Eliminarea urinară de albumină evaluată cu ajutorul raportului albumină/creatinină urinară a crescut odată cu creşterea indicelui de masă corporală atât la bărbaţi (normoponderali *vs*. supraponderali vs. obezi, 3 mg/g *vs*. 6,1 mg/g vs. 8,9 mg/g, p-0,018), cât şi la femei (normoponderali vs. supraponderali *vs*. obezi, 2,1 mg/g vs. 6,7 mg/g *vs*. 9,1 mg/g, p=0,03). Nu au existat diferenţe în ceea ce priveşte eliminarea urinară de albumină între cele două sexe (tab. II). Dintre subiecţii analizaţi, microalbuminuria a fost prezentă la 5 subiecţi (4,27%), dintre care 3 bărbaţi (4,69%) şi 2 femei (3,77%). Distribuţia subiecţilor cu microalbuminurie în funcţie de indicele de masă corporală, a fost următoarea: 2 subiecţi supraponderali (un bărbat şi o femeie) şi 3 subiecţi obezi (2 bărbaţi şi o femeie).

Analiza relaţiilor dintre parametrii analizaţi şi eliminarea urinară de albumină

La toţi bărbaţii nediabetici incluşi în studiu, în analiza univariată, raportul albumină/creatinină urinară s-a corelat pozitiv cu tensiunea arterială sistolică (r=0,46, p=0,0003) şi s-a corelat negativ cu adiponectina (r=-0,26, p=0,047) (tabel 3). La bărbaţii neobezi, raportul albumină/creatinină urinară s-a corelat pozitiv cu tensiunea arterială sistolică (r=0,39, p=0,041). La bărbaţii obezi, raportul albumină/creatinină urinară s-a corelat pozitiv cu tensiunea arterială sistolică (r=0,51, p=0,006) şi s-a corelat negativ cu adiponectina (r=-0,43, p=0,021) (fig. 1).

La subiecţii obezi, corelaţia dintre raportul albumină/creatinină urinară şi adiponectină a rămas semnificativă din punct de vedere statistic după ajustarea pentru tensiunea arterială sistolică (coeficient de regresie = - 0,348; 95% interval de încredere, 0,0075, 0,059; p=0,042).

La toate femeile nediabetice incluse în studiu, în analiza univariată, raportul albumină/creatinină urinară s-a corelat pozitiv cu tensiunea arterială sistolică (r=0,471, p=0,001) (tab. IV). La femeile obeze, raportul albumină/creatinină urinară s-a corelat pozitiv cu tensiunea arterială sistolică (r=0,485, p=0,022). La femeile neobeze, raportul albumină/creatinină urinară s-a corelat pozitiv cu tensiunea arterială sistolică (r=0,421, p=0,041) (tab. IV).

DISCUŢII

În lucrarea de faţă, am arătat, la subiecţii nediabetici, fără afecţiuni cardiovasculare, existenţa unei corelaţii între creşterea masei de ţesut adipos şi creşterea eliminării de albumină (evaluată cu ajutorul raportului albumină/creatinină urinară), în concordanţă cu datele altor studii (21,22,23). Shaw (23) arată la populaţia din Asia de Sud, faptul că, obezitatea centrală (evaluată prin intermediul raportului talie/şold) se corelează independent cu albuminuria la subiecţi normoglicemici - rude de gradul I ale pacienţilor cu diabet zaharat tip 2.

De asemenea, am evidenţiat diferenţe atât în funcţie de sex, cât şi în funcţie de IMC, în ceea ce priveşte determinanţii eliminării urinare de albumină. La bărbaţii obezi, eliminarea urinară de albumină, la valori mai mici decât cele considerate necesare pentru stabilirea diagnosticului de microalbuminurie s-a corelat independent cu tensiunea arterială sistolică (pozitiv) şi cu adiponectina (negativ), în timp ce la

bărbații neobezi şi la femei, indiferent de IMC, s-a corelat numai cu tensiunea arterială sistolică. Tsioufis (24) arată că adiponectina este predictor negativ pentru albuminurie, independent de vârstă, IMC şi tensiunea arterială, la bărbați hipertensivi. Yano (21) arată diferențe între subiecții obezi şi neobezi în ceea ce privește determinanții microalbuminuriei. La subiecții obezi, nediabetici, microalbuminuria s-a corelat negativ cu adiponectina şi pozitiv cu tensiunea arterială şi glicemia, în timp ce, la subiecții neobezi, microalbuminuria s-a corelat pozitiv cu vârsta şi tensiunea arterială. Sharma (22) arată existența unei relații negative strânse între adiponectină şi albuminurie, adiponectina reglând albuminuria prin intermediul căii AMPK, care contribuie la inhibarea stresului oxidativ la nivelul podocitelor.

În această lucrare, nu am evidențiat existența unei corelații între markerii inflamatori şi eliminarea urinară de albumină. Yudkin et al (25) arată existența unei asocieri între markeri inflamatori (IL-6, TNF-α şi proteina C-reactivă) şi markeri ai disfuncției endoteliale (factor von Willebrand, trombomodulina, fibronectina şi albuminuria). Astfel, TNF-α s-a corelat pozitiv cu factorul von Willebrand, trombomodulina, fibronectina şi albuminuria, IL-6 s-a corelat pozitiv cu albuminuria, în timp ce proteina C-reactivă s-a corelat pozitiv cu factorul von Willebrand şi fibronectina.

CONCLUZII

Aceste rezultate arată că la bărbații obezi, nediabetici, fără afecțiuni cardiovasculare, adiponectina are un rol important în controlul eliminării urinare de albumină.

THE LYMPH NODES STATUS – PROGNOSTIC FACTOR IN BREAST CANCER (Abstract): **Aim**: The assessment of the survival rate according to axillary lymph nodes status in patients diagnosed with breast cancer. **Material and methods**: The study group included 206 women, treated in the 4th Obstetrics and Gynecology Clinic during 2002-2005. All patients were treated surgically with lymph nodes dissection. The analyzed variables included clinical and morphological features of both primary tumor and axillary lymph nodes. We have evaluated 5 years survival in relation to positivity and number of dissected lymph nodes. In order to determine the prognostic value of evaluated variables we have used Kaplan Meir method. **Results**: 77.7% of all patients were aged between 40 and 49 years old and 62.6% of them presented stage II tumors. Invasive ductal carcinoma was the most frequent histologic type (79.12%) and 71.2% of tumors were moderated of poorly differentiated, lymph nodes invasion being presented in 93 cases. Survival was significantly influenced by lymph node status ($p = 0.0001$), number of involved nodes ($p = 0.0001$), number of dissected nodes in pN0 patients ($p = 0.0001$) and application of adjuvant systemic therapy in pN0 patients ($p = 0.0001$). **Conclusions**: The pathological examination of axillary nodes in breast cancer patients offers a valuable information regarding survival. The absence of lymph node metastases of 10 lymph nodes dissection or more, and the application of adjuvant systemic therapy favorably influence the survival. **Keywords**: BREAST CANCER, LYMPH NODES, PROGNOSTIC FACTOR

Cancerul mamar reprezintă o importantă problemă de sănătate publică la nivel mondial, prognosticul acestei afecţiunii fiind influenţat de factori precum dimensiunea tumorii, tipul histologic, gradul de diferenţiere, statusul receptorilor hormonali, statusul limfoganglionilor limfatici şi vârsta pacientei (1). Invazia limfoganglionilor locoregionali constituie principalul factor care condiţionează instituirea terapiei adjuvante (2,3). Tehnica chirurgicală standard presupune disecţia staţiilor limfatice I şi II Berg, procedură cu viză curativă care oferă importante informaţii prognostice. Limfadenectomia axilară este grevată de o rată crescută de morbiditate, fapt care a condus la promovarea investigaţiei limfoganglionului santinelă (4-6).

Studiul nostru are drept obiectiv analiza statusului limfoganglionilor axilari şi investigarea corelaţiilor existente între acest factor prognostic major şi alţi factori (consideraţi minori) care caracterizează tumora, pentru a pune în evidenţă valoarea independentă a invaziei tumorale, în relaţie cu supravieţuirea.

MATERIAL ŞI METODE

Studiul retrospectiv, descriptiv şi analitic a inclus 206 paciente diagnosticate şi tratate pentru cancer mamar în stadiile I-III în Clinica IV Obstetrică Ginecologie, Spitalul Clinic de Obstetrică Ginecologie "Cuza Vodă" Iaşi, în perioada 2002-2005.

Etapele alcătuirii lotului şi analiza foilor de observaţie s-au desfăşurat în conformitate cu principiile eticii cercetării medicale, în baza consimţământului informat al pacientelor pentru folosirea datelor în concordanţă cu obiectivele specifice ale studiului.

Variabilele analizate au fost reprezentate de vârstă, stadiul clinic, prezenţa şi tipul tratamentului adjuvant, dimensiunea tumorii, tipul histologic, gradul de diferenţiere celulară, prezenţa invaziei spaţiului vasculolimfatic, statusul receptorilor hormonali, statusul limfoganglionilor axilari, numărul de limfoganglioni pozitivi în cazul stadiului pN0.

Datele obţinute au fost analizate şi exprimate procentual, diferenţele dintre valorile medii ale parametrilor investigaţi au fost analizate prin intermediul testelor t student şi ANOVA, iar asocierile dintre diferiţi factori au fost interpretate cu ajutorul testelor de corelaţie şi regresie. Influenţa variabilelor analizate asupra supravieţuirii la 5 ani a fost efectuată cu ajutorul metodei Kaplan Meir. Prelucrarea statistică a fost realizată cu programul *Statistica* 8.0.

REZULTATE

Din totalul celor 206 paciente analizate, 160 cazuri (77,7%) au avut vârsta cuprinsă între 40-69 de ani, iar 129 paciente (62,6%) s-au aflat în stadiul II evolutiv. În 39 de cazuri (18,9%) s-a instituit doar tratament chirurgical, în restul de 69,1% din cazuri acesta fiind complementat de radio (71%) şi chimioterapie (69,7%) (tab. I).

TABELUL I

Distribuţia pacientelor funcţie de caracteristicile clinice şi de tratamentul instituit

Parametru	Nr. Cazuri	Procent
Vârsta		
< 40 ani	14	6,77%
40-69 ani	32	15,53%
>70 ani	160	77,7%
Stadiul clinic		
I	45	21,84%
II	129	62,6%
III	32	15,53%
Tratament		
Exclusiv chirurgical	39	18,9%
Chimioterapie	116	69,7%
Hormonoterapie	77	46,3%
Radioterapie	119	71%

Din lotul cuprins în studiu 163 de paciente (79,12%) au prezentat carcinom ductal invaziv (CDI). Majoritatea tumorilor diagnosticate au fost moderat (36,89%) şi slab diferenţiate (34,95%). Invazia spaţiului vasculolimfatic (ISVL) a fost prezent în 93 de cazuri (45,15%). Tumorile identificate au fost de mici dimensiuni (<2 cm) la 116 de paciente (56,31%), între 2-5 cm în 82 de cazuri (39,81%) şi mai mari de 5 cm în 8 cazuri (3,88%). Statusul receptorilor hormonali estrogenici (RE) şi progesteronici (PR) a fost evaluat în 93 de cazuri (45,14%) cu o rată de pozitivitate de 50,5% în cazul RE şi de 37,7% în cazul RP (tab. II).

TABELUL II

Distribuţia pacientelor funcţie de caracteristicile tumorii

Parametru	Valoare	Procent
Tip histologic		
CDI	163	79,12%
CLI	33	16,02%
Alte tipuri	20	9,76%
Gradul histologic		
I	58	28,16%
II	76	36,89%
III	72	34,95%
ISVL		
Da	93	45,15%
Nu	113	54.85%
pT		
<2 cm	116	56,31%
2-5 cm	82	39,81%
> 5 cm	8	3,88%
Statusul receptorilor		
ER +	47	50,5%
PR +	35	37,7%

În 128 (62,13%) de cazuri statusul limfoganglionilor limfatici axilari a fost negativ (pN0), iar în cazul pacientelor cu limfoganglioni pozitivi (37,87%) numărul limfoganglionilor afectaţi a fost de 3 în 52,3% din cazuri, 4-9 în 28,7% din cazuri, şi de ≥ 10 la 19,9% dintre paciente.

Rata de supravieţuire la 5 ani a fost de 88,3% în cazul pacientelor cu limfoganglioni negativi şi de 74,7% în cazul prezenţei de limfoganglioni axilari pozitivi ($p < 0,00001$). În cazul pacientelor cu 3 limfoganglioni pozitivi supravieţuirea a fost de 79,5%, spre deosebire de 53,9% în cazul pacientelor cu 10 sau mai mulţi limfoganglioni invadaţi metastatic ($p<0,00001$) (tab. III).

Stabilirea stadiului pN0 a fost realizată în raport de numărul limfoganglionilor disecaţi, acesta fiind peste 10 în 86,9% din cazuri şi peste 16 în 52% din cazuri. Am remarcat o relaţie directă între numărul limfoganglionilor disecaţi şi supravieţuirea la 5 ani, anume 76,9% în cazul pacientelor cu mai puţin de 10 limfoganglioni excizaţi, 88,7% pentru pacientele cu 10-16 limfoganglioni disecaţi şi 92,3% în cazul celor la care s-au excizat mai mult de 16 limfoganglioni (fig. 1).

TABELUL III

Evaluarea supravieţuirii la 5 ani funcţie de caracteristicile limfoganglionilor axilari

Parametru	Supravieţuire 5 ani	P
Statusul limfoganglionilor

Da	89,3%	0,0000
Nu	71,4%	

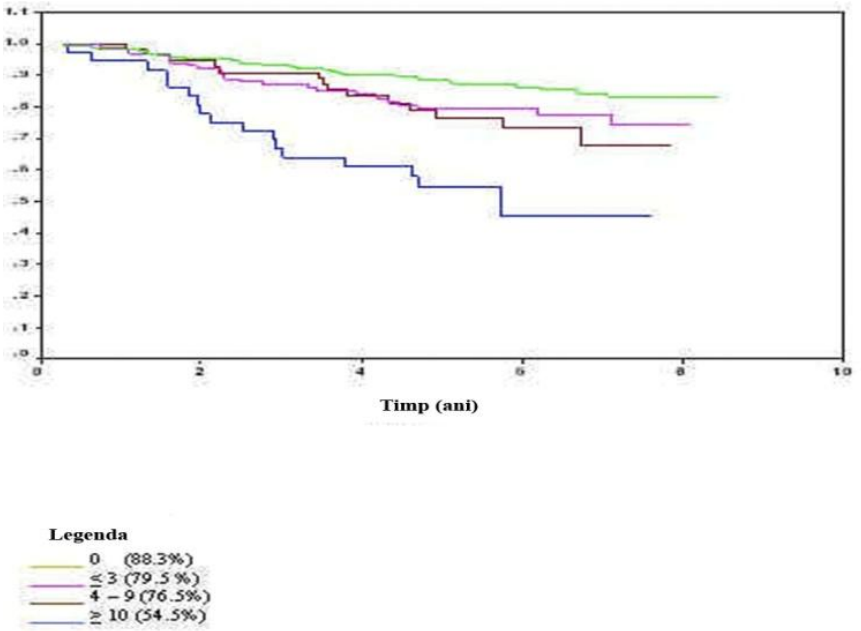

Fig. 1. Supravieţuirea la 5 ani în funcţie de numărul limfoganglionilor invadaţi metastatic

În cazul pacientelor aflate în stadiul pN0 care au primit terapie sistemică supravieţuirea la 5 ani a fost de 88,93%, spre deosebire de 71,4% în cazul celor care nu au beneficiat de acest tratament (p<0,00001).

DISCUŢII

Vârsta reprezintă un factor de risc pentru apariţia cancerului mamar. Un studiu efectuat pe 35769 paciente diagnosticate cu cancer mamar raportează că 81,7% dintre acestea aveau vârsta peste 46 de ani, iar 36,3% peste 65 de ani (7). Lotul investigat a relevat o creştere de 6,7 ori a incidenţei, în raport de vârstă. În ceea ce priveşte dimensiunea tumorilor, leziunile mai mici de 2 cm au fost cele mai frecvente, similar cu raportările din alte publicaţii (8). Procentajul de paciente diagnosticate în stadiul I a fost mai mic în cazul prezentei cercetări (21,84%) comparativ cu date prezentate în literatură (48%, respectiv 34,5%) (7). Carcinomul ductal invaziv a fost tipul histologic predominant, rezultat similar concluziilor altor cercetări (9). Rezultatele noastre referitoare la gradul de diferenţiere au fost însă neconcordante cu literatura, lotul nostru de studiu incluzând un procent mai mare, aproape 30%, de tumori bine diferenţiate.

Toate pacientele incluse în studiu au fost tratate chirurgical, radical sau conservator, iar aplicarea terapiei complementare, adjuvantă sau neoadjuvantă, a fost indicată în raport de: stadiul clinic, evaluarea histopatologică, care a permis stabilirea gradului de extensie al afecţiunii, şi alte caracteristici prognostice (gradul de diferenţiere, ISVL, statusul receptorilor). Prezenţa invaziei spaţiului vasculo-limfatic a fost raportată cu frecvenţe variabile între 20-50% probabil datorită dificultăţii de diferenţiere între vasele sangvine şi artefactele generate de retracţia tisulară, mai ales dacă sunt

folosite strict criteriile morfologice (10).

Invazia spaţiului limfovascular este considerată unul dintre principalii factori de risc pentru recidiva după tratamentul conservator. În ceea ce priveşte frecvenţa metastazelor în limfoganglionii limfatici şi numărul mediu de limfoganglioni invadaţi, rezultatele noastre sunt similare cu cele raportate de alţi autori (6). Supravieţuirea pacientelor diagnosticate cu cancer mamar este redusă considerabil în cazul prezenţei metastazelor limfatice, acesta fiind cel mai important factor de risc de recurenţă. Mai mult decât atât, prognosticul este influenţat de numărul limfoganglionilor limfatici invadaţi, acest parametru fiind considerat cel mai important factor de prognostic al recurenţelor la paciente cu limfoganglioni pozitivi. În majoritatea cazurilor au fost disecaţi minimum 10 limfoganglioni, în conformitate cu indicaţiile din literatură. Necesitatea implementării chimioterapiei sistemice la bolnavele cu limfoganglioni neinvadaţi (pN0) este condiţionată de numărul ganglionilor disecaţi.

În cazul pacientelor cu metastaze ganglionare, numărul limfo-ganglionilor disecaţi nu a influenţat semnificativ supravieţuirea, spre deosebire de pacientele aflate în stadiul pN0, la care numărul limfoganglionilor excizaţi a ameliorat supravieţuirea, mai ales în cazul asocierii terapiei sistemice. Cu excepţia numărului mic de paciente diagnosticate în stadiul I şi rata redusă de utilizare a hormonoterapiei, restul caracteristicilor clinice, morfologice şi terapeutice au fost asemănătoare cu cele regăsite în literatură.

CONCLUZII

Evaluarea corectă a statusului limfoganglionilor axilari a demonstrat rolul de factor prognostic major al acestui parametru morfologic. Acurateţea evaluării precum şi creşterea ratei de supravieţuire la 5 ani este în directă relaţie cu numărul ganglionilor excizaţi. Studiul nostru arată o relaţie directă între numărul limfoganglionilor disecaţi şi supravieţuirea la 5 ani, 76,9% în cazul pacientelor cu mai puţin de 10 limfoganglioni excizaţi, 88,7% pentru pacientele cu 10-16 limfoganglioni disecaţi şi 92,3% în cazul celor la care s-au excizat mai mult de 16 limfoganglioni.

Completarea tratamentului chirurgical cu chimioterapia chiar si la pacientele cu un status limfoganglionar pNo este utilă. Rezultatele studiului nostru demonstrează că pentru grupul pacientelor aflate în stadiul pN0 care au primit terapie sistemică supravieţuirea la 5 ani a crescut cu 17,53%.

NOUTĂȚI

VITAMINA D ŞI PROTECŢIA ANTICANCER I

Având în vedere studiile recente care menţionează potenţialul antitumoral al concentraţiilor eficiente de vitamina D, metaanaliza publicată de Manson şi colaboratorii, în ultimul număr al New England Journal of Medicine, îşi propune să revizuiască articolele principale care au evidenţiat utilizarea vitaminei D în bolile sistemului articular dar şi în trialurile în care s-au urmărit beneficiile antitumorale şi de stimulare a imunităţii. În ceea ce priveşte beneficiile asupra sănătăţii osoase, doza zilnică recomandată este de 600 UI pentru persoane sub 70 de ani şi de 800 UI la vârste de peste 70 de ani. Autorii metaanalizei au arătat că majoritatea studiilor efectuate până în prezent nu au fost randomizate şi nu au urmărit ca obiectiv principal potenţialul antitumoral. Majoritatea informaţiilor provin din studii de laborator, corelaţii de natură ecologică, sau studii care au dozat nivelul vitaminemiei D la pacienţii diagnosticaţi cu tumori maligne. În literatură au fost evidenţiate trei trialuri principale, inclusiv unul în care administrarea vitaminei D şi calciu a fost comparată cu administrarea izolată a calciului, parametrii urmăriţi fiind numărul de cazuri noi de cancer nou diagnosticate şi mortalitatea prin cancer. În cazul cancerului de sân, administrarea pe termen lung a unor doze suplimentare de vitamina D a fost urmată de creşterea incidenţei tumorale, iar pentru cancerul de colon administrarea de vitamină D a fost urmată de scăderea riscului. În ciuda unor ipoteze patogenice plauzibile, dovezile privind utilizarea vitaminei D pentru profilaxia antitumorală sunt inconsistente. (Manson JE, Susan PH, et al. Vitamin D and prevention of cancer – ready for prime time?, *N Engl J Med* 2011; 364 (15): 1385-7)

ASSESSMENT TUMOR MARKERS BY IMMUNOHISTOCHEMISTRY (Ki67, p53 AND Bcl-2) ON A COHORT OF PATIENTS WITH CERVICAL CANCER IN VARIOUS STAGES OF EVOLUTION (Abstract): In defining new potential prognostic factors in cervical cancer, p53 protein expression, Ki67 or issues related to Bcl-2 oncogene involved in cellular apoptosis process, have been the subject of numerous publications. This paper aims to study with immunohistochemical methods, the way in which these factors are involved in influencing the prognosis of patients with cervical cancer. The study was conducted on 42 pieces operators from the same number of patients diagnosed with this disease, aged between 25-65 years and in different clinical stages. We used an experimental design type 2 (histopathological type squamous cell / adenocarcinoma) x 3 (degree of differentiation weak / moderate / well differentiated) x 4 (stage I / II / III / IV disease). Diagnosis was based on clinical examination and confirmed by histopathology, and hypothesis testing we used Kruskal-Wallis ANOVA test of ranks test, Mann-Whitney U test, χ 2 test, Spearman's correlation test and crosstabs ranking difference. The results on the study group showed the prognostic value of both the proliferation marker Ki67 and p53 oncogene, the presence of tandem Ki67 / p53 in cervical carcinoma meaning more so a poor prognosis, Bcl-2 overexpression was detected in none of the 42 cases investigated. Key words: Ki67, p53, Bcl-2, PROLIFERATIVE ACTIVITY, IMMUNOHISTOCHEMISTRY, PROGNOSIS, CERVICAL CANCER

Deşi neoplasmul de col uterin este o afecțiune ce poare fi prevenită, în România încă reprezintă o problemă de sănătate publică prin lipsa unor programe de scrining, şi o deficiență în educația pentru sănătate a populației. Această situație particulară a incidenței şi mortalității prin cancer de col uterin care se înregistrează în țara noastră, alături de unele posibilități de explorare şi de analiză histopatologică au creat premisele necesare care ne-au determinat să alegem studierea neoplasmului de col uterin drept temă de cercetare.

În ceea ce priveşte investigarea unor biomarkeri, rezultatele studiilor publicate încă sunt contradictorii şi în parte incomplete. Totuşi, pe lângă valoarea lor prognostică, inhibarea acestor biomarkeri ar

putea avea efect terapeutic în mai multe situații.

Dezvoltarea fără precedent a biologiei moleculare în ultimii ani a permis depistarea unor anomalii cromozomice precizând astfel etapele carcinogenezei uterine şi orientând cercetările spre definirea unor noi factori prognostici potențiali. Dintre aceştia expresia proteinelor p_{53}, Ki67 sau aspecte legate de prezența oncoproteinei Bcl-2 cu rol în procesul de apoptoză celulară au făcut obiectul a numeroase publicații.

Studiile publicate au demonstrat semnificația prognostică a fiecăruia din markerii menționați cât şi corelațiile dintre aceştia şi factorii prognostici clasici.

OBIECTIVE

Lucrarea de față are ca obiectiv studierea cu ajutorul metodelor imunohistochimice a modului în care markerii de proliferare celulară (Ki67 şi p_{53}) precum şi oncoproteina Bcl-2 sunt implicați în influențarea prognosticului pacientelor cu cancer de col uterin. S-a încercat identificarea modului în care valorile acestora influențează tipul histopatologic, gradul de diferențiere şi stadiul clinic al tumorii şi dacă există corelații între gradul de exprimare al acestor markeri celulari.

Ne-am aşteptat ca nivelul markerilor de proliferare celulară Ki67 şi p_{53}, precum şi a oncoproteinei Bcl-2 în tumoră să influențeze prognosticul bolii; cu cât nivelul Ki67 şi p_{53} va fi mai crescut, iar cel al oncogenei Bcl-2 mai scăzut în prelevatele tisulare, cu atât prognosticul pacientelor va fi mai grav.

MATERIAL ŞI METODĂ

Cercetarea a fost efectuată pe un număr de 42 piese operatorii provenind de la acelaşi număr de paciente diagnosticate cu cancer de col uterin, internate în cadrul Clinicii Chirurgie – Compartimentul Ginecologie al Spitalului Clinic Militar de Urgență „Dr. Iacob Czihac" Iaşi, în perioada 2007-2010. Pacientele au avut vârsta cuprinsă între 25-65 ani, aflate în stadii clinice diferite şi proveneau atât din mediul urban, cât şi din mediul rural. Modul de selectare a acestor piese a ținut cont de materialul biologic care a trebuit să fie suficient pentru studiul morfologic şi imunohistochimic. Prelevatele tisulare au fost fie piese operatorii, fie biopsii de col uterin efectuate pentru precizarea diagnosticului. Diagnosticul s-a bazat pe examenul clinic şi a fost confirmat de examenul histopatologic al fragmentelor de biopsie a colului uterin şi al pieselor de rezecție chirurgicală. Piesele de rezecție şi prelevatele de biopsie au fost examinate şi prelucrate în cadrul Laboratorului de Anatomie Patologică al Spitalului Clinic Militar de Urgență „Dr. Iacob Czihac" Iaşi.

S-au utilizat ca instrumente de culegere a datelor foile de observație ale pacientelor, registrele de protocoale operatorii şi registrul examenelor anatomo-patologice. S-au studiat datele clinice şi aspectele anatomo-patologice tumorale – macroscopia, microscopia şi stadiul patologic. S-a utilizat, de asemenea, programul de prelucrare statistică a datelor *SPSS 13.0* şi Microsoft Office Excel 2003 pentru realizarea graficelor.

Ca metodă statistică, pentru verificarea ipotezelor, am utilizat tehnicile neparametrice *ANOVA Kruskal-Wallis* al rangurilor, *testul U a lui Mann-Whitney*, *testul chi 2* (hi patrat), *crosstabs* şi *testul Spearman al corelatiei* diferenței rangurilor.

Metoda histopatologică a presupus examinarea anatomo-patologică a pieselor tumorale, descrierea macroscopică, microscopică şi imunohistochimică. Examenul

microscopic s-a realizat utilizând colorația standard (hematoxilină-eozină) şi colorații speciale pentru componentele celulare, tisulare şi a mucusului (Van Gieson, Albastru Alcian). De asemenea, imunohistochimia a permis o analiză structurală şi fenotipică, utilizând criteriul molecular în diagnosticul histopatologic şi oferind date privind diferențierea, histogeneza şi progresia tumorală.

S-a interpretat o reacție *p_{53}* pozitivă colorarea nucleară distinctă, omogenă sau granulară. Produsul de reacție a prezentat culoare brună. Am considerat de asemenea, că tumorile supraexprimă proteina p_{53} numai când am obținut o colorație nucleară intensă, prezentă într-unul din cele 3 pattern-uri. Cazurile cu o colorație nucleară echivocă sau slabă le-am considerat negative. Tot negative am considerat şi cazurile cu nuclei pozitivi extrem de rari sau izolați. Am folosit un sistem de gradare pentru evaluarea reactivității *p_{53}* notând astfel: 0 colorația negativă; + reacție pozitivă în mai puțin de 10% din nucleii celulelor tumorale; ++ reacție pozitivă în mai mult de 10% din nucleii celulelor tumorale dar mai puțin de 33%; +++ reacție pozitivă în mai mult de 33% din nucleii celulelor tumorale. (Ivan, Mihailovici, 2004), (1).

Pentru Ki67 am considerat ca pozitivă orice colorare nucleară detectabilă (punctiformă sau difuză), iar în vederea cuantificării imunoreacției Ki67 am determinat procentul de celule reactive. Pornind de la heterogenitatea în distribuția şi intensitatea colorării, pentru a evita subiectivitatea şi dificultățile în aprecierea rezultatelor, am utilizat un scor semnificativ (corespunzător intensității colorării şi procentului de nuclei reactivi), care a permis clasificarea imunoreactivității Ki67 în trei grupe de scor: scor jos (malignitate joasă) – s-au colorat între 5-20% dintre nucleii celulelor tumorale; scor mediu (malignitate intermediară) - s-au colorat 20-70% dintre nucleii celulelor tumorale; scor înalt (malignitate înaltă) – s-au colorat peste 70% din nucleii celulelor tumorale .

Marcarea imunohistochimică a anti-oncoproteinei Bcl-2, AM287-5M a identificat un pattern de colorare membranară.

REZULTATE

1. analiza vârstei pacientelor a surprins următoarele date: în studiu sunt 31% din paciente cu vârsta cuprinsă între 25-35 ani, 28,6% paciente cu vârsta cuprinsă între 56-65 ani, 26,2% paciente cu vârsta cuprinsă între 46-55 ani şi 14,3% paciente cu vârsta cuprinsă între 36-45 ani.

a) analiza ***tipului histopatologic:*** *$\chi 2$ = 21,36 este semnificativ: p<0,001, la 3 grade libertate.*

- *pentru tipul scuamocelular* 43,3% cazuri cu vârsta cuprinsă între 25-35 de ani, 33,3% cazuri cu vârsta cuprinsă între 56-65 ani şi 23,3% cazuri cu vârsta cuprinsă între 46-55 ani;

- pentru *tipul adenocarcinom*, 50% cazuri la pacientele cu vârsta cuprinsă între 36-45 ani, 33,3% cazuri cu vârsta cuprinsă între 46-55 ani şi 16,7% cazuri cu vârsta cuprinsă între 56-65 ani;

b) analiza ***gradului de diferențiere***: *χ 2=20,33 este semnificativ: p=0,002, la 6 grade libertate;*

- pentru gradul *slab diferențiat:* 58,3% cazuri cu vârsta cuprinsă între 25-35 de ani, 41,7% cazuri cu vârsta cuprinsă între 46-55 ani;

- pentru gradul *moderat diferențiat*: 50% din cazuri cu vârsta cuprinsă între 56-65, 33,3% cazuri cu vârsta cuprinsă între 25-35 ani şi 16,7% cazuri cu vârsta cuprinsă între 46-55 ani.

- pentru gradul *bine diferenţiat*: 33,3% din cazuri cu vârsta cuprinsă între 36-45 şi 56-65 ani, 22,2% cazuri cu vârsta cuprinsă între 46-55 ani şi 11,1% cazuri cu vârsta cuprinsă între 25-35 ani.

c) analiza ***stadiului bolii:*** *χ 2=25,83 este semnificativ: p=0,002, la 9 grade libertate; r = - 0,015, p = 0,92, r^2 = 0,0002.*

- în *stadiul avansat (IV):* 66,7% cazuri cu vârsta cuprinsă între 46-55 ani şi 16,7% cazuri cu vârsta cuprinsă între 36-45 ani, respectiv 25-35 ani;

- în *stadiul III*: 41,7% paciente cu vârsta cuprinsă între 25-35 ani, 33,3% cazuri cu vârsta cuprinsă între 56-65 ani şi 25% cazuri cu vârsta cuprinsă între 46-55 ani;

- în *stadiul II*: 66,7% paciente cu vârsta cuprinsă între 56-65 ani şi 33,3 % paciente cu vârsta cuprinsă între 25-35 ani;

- în *stadiul I*: câte 33,3% cazuri de paciente cu vârsta cuprinsă între 25-35 ani, 36-45 ani şi 56-65 ani.

2) studiul asocierii markerului de proliferare Ki67 cu oncogena p_{53}: *χ 2=3 ,66 este semnificativ: p < 0,001 la 4 grade libertate;* r = 0,837; p < 0,001, r^2 = 0,70.

TABELUL I

Asocierea dintre gradul de malignitate Ki67 si pozitivitatea p53

			P53			
			+ (pozitiv 10%	++ (pozitiv intre 11-33%)	+++ (pozitiv peste 33%)	Total
Ki67	malignitate joasă (5%-20%)	număr cazuri	12	6	0	18
		% din p53	100,0%	50,0%	,0%	42,9%
		% din total	28,6%	14,3%	,0%	42,9%

		% din p53	,0%	50,0%	66,7%	42,9%
		% din total	,0%	14,3%	28,6%	42,9%
	malignitate înaltă (>70%)	număr cazuri	0	0	6	6
		% din p53	,0%	,0%	33,3%	14,3%
		% din total	,0%	,0%	14,3%	14,3%
Total		număr cazuri	12	12	18	42
		% din p53	100,0%	100,0%	100,0%	100,0%
		% din total	28,6%	28,6%	42,9%	100,0%

3) studiul asocierii Ki67 cu tipul histopatologic; influenţa tipului histopatologic asupra scorului de malignitate al Ki67: incidenţa lui Ki67 este de 71,4% în cazurile de carcinom scuamocelular şi de 28,6% în cazuile de adenocarcinom; Ki67 cu malignitate înaltă este prezent 100% în cazurile de adenocarcinom, Ki67 cu malignitate intermediară prezent 100% în cazurile de carcinom scuamocelular, iar Ki67 cu malignitate joasă este prezent 66,7% în cazurile de carcinom spinocelular şi 33,3% în cazurile de adenocarcinom; ***Chi-pătrat = 22,400; df = 2, p < 0,001;*** U = 144, p = 0,27; r = 0,17; p = 0,28.

4) studiul asocierii p_{53} cu tipul histopatologic; influenţa tipului histopatogic asupra oncogenei p_{53}: incidenţa p_{53} este de 71,4% în cazurile de carcinom scuamocelular şi de 28,6% în cazurile de adenocarcinom; p_{53}+ este prezent 50% şi în cazurile de carcinom scuamocelular şi în cele de

adenocarcinom, p_{53}++ este prezent 100% în cazurile de carcinoma scuamocelular, iar p_{53}+++ este prezent 66,7% în cazurile de carcinom scuamocelular şi 33,3% în cazurile de adenocarcinom: Chi-pătrat = 7,70; df = 2, p = 0,021; U = 162, p = 0,592; r = - 0,08; p = 0,598.

5) studiul asocierii Ki67 cu gradul de diferenţiere; influenţa gradului de diferenţiere asupra scorului de malignitate al Ki67: incidenţa Ki67 este de 42,9% în cazurile bine diferenţiate şi câte 28,6% în cazurile slab şi moderat diferenţiate; Ki67 cu malignitate înaltă este prezent 100% în cazurile bine diferenţiate, Ki67 cu malignitate intermediară prezent 66,7% în cazurile slab diferenţiate şi 33,3% în cele moderat diferenţiate, iar Ki67 cu malignitate joasă este prezent 66,7% în cazurile bine diferenţiate şi 33,3% în cele moderat diferenţiate: Chi-pătrat = 32,667; df = 4, p < 0,001; ANOVA Kruskal Wallis: Chi-pătrat =4.84, df = 2, p = 0.089; r = - 0,26; p = 0,089.

6) studiul asocierii p_{53} cu gradul de diferenţiere; influenţa gradului de diferenţiere asupra oncogenei p_{53}: incidenţa p_{53} este de 42,9% în cazurile bine diferenţiate şi câte 28,6% în cazurile slab şi moderat diferenţiate; p_{53}+ este prezent 100% în cazurile bine diferenţiate, p_{53}++ este prezent câte 50% în cazurile slab şi moderat diferenţiate, iar p_{53}+++ este prezent câte 33,3% în toate cele trei tipuri de diferenţiere: Chi-pătrat = 25,667; df = 4, p < 0,001; ANOVA Kruskal Wallis: Chi-pătrat =8.61, df = 2, p = 0.014; r = - 0,42; p = 0,006.

7) studiul asocierii Ki67 cu stadiul clinic; influenţa stadiului clinic asupra scorului de malignitate al Ki67: incidenţa Ki67 este de 28,6% în fiecare din stadiile I, III şi IV, iar în stadiul II de 14,3%; Ki67 cu malignitate înaltă este prezent 100% în stadiul IV, Ki67 cu malignitate intermediară prezent 66,7% în stadiul III şi 33,3% în stadiul IV, iar Ki67 cu malignitate joasă este prezent 66,7% în stadiul I şi 33,3% în stadiul II: Chi-pătrat = 56; df = 6, p < 0,001; ANOVA Kruskal Wallis: Chi-pătrat =37,58; df = 3; p < 0,001; r = 0,912; p < 0,001.

8) studiul asocierii p_{53} cu stadiul clinic; influenţa stadiului clinic asupra gradului de pozitivitate al p_{53}: incidenţa p_{53} este de 28,6% în fiecare din stadiile I, III şi IV, iar în stadiul II de 14,3%; p_{53}+ este prezent câte 50% în stadiile I şi II, p_{53}++ este prezent câte 50% în stadiile I şi III, iar p_{53}+++ este prezent 66,7% în stadiul IV şi 33,3% în stadiul III: Chi-pătrat = 45,50; df = 6, p < 0,001; ANOVA Kruskal Wallis: Chi-pătrat =32,59; df = 3; p < 0,001; r = 0,806; p < 0,001.

DISCUŢII

Studiul demonstrează că ***vârsta*** pacientelor din lot se asociază semnificativ cu: tipul histopatologic (la vârsta 25-35 ani predomină carcinomul scuamocelular, faţă de adenocarcinom care predomină în următoarea categorie de vârstă (36-45 de ani), cu gradul de diferenţiere (la vârsta tânără predomină gradul de diferenţiere slab diferenţiat, faţă de cel bine diferenţiat care predomină la vârsta înaintată), cu stadiul bolii (stadiul foarte avansat (IV) predomină în categoria de vârstă 46-55 ani, pe când stadiul incipient al bolii – în categoria premergătoare acesteia, 36-45 ani). Putem spune că pacientele tinere vor avea un prognostic mai rezervat decît cele cu vâstă mai înaintată.

Supraexpresia Bcl-2 nu a fost decelată în nici una din cele 42 de cazuri cercetate, astfel încât a fost imposibil de demonstrat

importanţa ei în ceea ce priveşte prognosticul pacientelor cu cancer de col uterin, deşi unii cercetători susţin că în ceea ce priveşte carcinogeneza cervicală, supraexpresia acestei proteine poate fi determinată în fiecare stadiu al patogenezei, sau că distribuţia şi intensitatea imunoreacţiei Bcl-2 corelează semnificativ cu gradul de diferenţiere al tumorii, acest lucru putând fi un important factor adjuvant în stabilirea unui prognostic corect. Alţi autori găsesc că nu este un factor de predicţie al prognosticului în cancerul cervical.

Analiza studiului markerului de proliferare Ki67 în ceea ce priveşte tipul histopatologic a relevat faptul că a*socierea dintre procentul Ki67 şi tipul histopatologic s-a dovedit a fi statistic semnificativă, expresia Ki67 aflându-se într-un procent semnificativ mai mare în tipul scuamocelular decât în adenocarcinomul de col uterin, dar* cazurile de malignitate înaltă s-au decelat doar în adenocarcinoamele de col uterin. Acest lucru demostrează că prezenţa markerului de proliferare Ki67 cu malignitate înaltă la pacientele cu neoplasm de col uterin va determina un prognostic rezervat.

Analiza studiului markerului de proliferare Ki67 legat de grading-ul tumoral ne permite să concluzionăm că *expresia Ki67 se află într-un procent semnificativ mai mare în tipul bine diferenţiat, comparativ cu tumora de col uterin cu grad de diferenţiere moderat sau slab.* Prin studiul corelaţiei am identificat *existenţa unei corelaţii invers proporţionale, slabe, şi nesemnificative între gradul de malignitate al Ki67 şi gradul de diferenţiere a tumorii.*

De asemenea, analiza stadiului clinic a evidenţiat o a*sociere semnificativă dintre procentul Ki67 şi stadiu bolii: am observat o asociere a scorului crescut şi intermediar de malignitate cu stadiul bolii avansat (stadiul III şi IV) şi invers. Mai mult, s-a putut observa că valorile Ki67 au înregistrat modificări semnificative în funcţie de stadiul bolii, astfel că, în stadiile III şi IV rangurile medii ale Ki67 au fost semnificativ mai mari comparativ cu cele din stadiile I şi II. Totodată sa evidenţiat şi existenţa unei corelaţii pozitive, puternice şi semnificative între gradul de malignitate al Ki67 şi stadiul bolii: pe lotul studiat, cu cât malignitatea Ki67 a fost mai mare, cu atât a crescut stadiul bolii şi invers. Astfel, putem aprecia un prognostic nefavorabil al pacientelor cu valori mari ale lui Ki67.*

În studiile lui Veronese et. al. (1993), (2) detecţia antigenului Ki67 s-a dovedit superioară metodei de determinare a gradului histologic de diferenţiere sau a indexului mitotic şi consideră că, indiferent de tipul histologic, toate tumorile cu peste 5% celule Ki67 pozitive, au un curs clinic nefavorabil. Bouzubar şi colab (1989), (3) susţin că tumorile în care valoarea lui Ki67 este peste 20% au un risc crescut de recădere, Wintzer şi colab (1991), (4), au raportat un prognostic mai sever la pacienţii cu tumori având valori ale lui Ki67 mai mari decât 16%, în timp ce alţi autori notează o probabilitate mai mică de supravieţuire la 5 ani a pacienţilor cu valori ale lui Ki67 mai mari de 13% (Nakano, Oka 1993), (5).

Cu cât activitatea proliferativă a unei tumori este mai mare, cu atât este mai mare potenţialul său malign, iar supravieţuirea (din momentul diagnosticului) mai redusă (Tsamandas et al., 2009, Ivan, Toma 2009), (6), (7). Chen şi colab. (2008), (8), arată că valoarea prognostică a markerului de proliferare Ki67 este redusă .

Analiza studiului oncogenei p_{53} pe lotul nostru de paciente, în ceea ce priveşte ***tipul histopatologic*** a evidenţiat că oncoproteina

p_{53} se află într-un procent semnificativ mai *mare în tipul scuamocelular decât în adenocarcinomul de col uterin. Această asociere este statistic semnificativă. În schimb, în tipul histopatologic scuamocelular valoarea lui p_{53} nu este semnificativ mai mare comparativ cu valoarea medie înregistrată în cazul adenocarcinomului de col uterin şi nici nu s-a evidenţiat existenţa unei corelaţii semnificative între gradul de pozitivitate al p_{53} şi tipul histopatologic.*

În studiul nostru *asocierea dintre procentul oncogenei p_{53} şi* ***gradul de diferenţiere al tumorii*** *este statistic semnificativă: cazurile slab şi moderat diferenţiate s-au asociat cu pozitivitate p_{53} intermediară (++) şi înaltă (+++), iar cele bine diferenţiate cu pozitivitate scăzută (+). Mai mult, valorile oncogenei p_{53} în tumorile slab şi moderat diferenţiate sunt semnificativ mai mari comparativ cu valorile aflate în tumorile bine diferenţiate, ceea ce ne permite să concluzionăm că, cu cât o tumoră va avea aspecte histologice bine diferenţiate, cu atât ne vom aştepta la un prognostic bun şi invers.* De asemenea, s-a evidenţiat *prezenţa unei corelaţii invers proporţionale, medie şi semnificativă între gradul de pozitivitate al p_{53} şi gradul de diferenţiere a tumorii. Pozitivitatea pentru p_{53} a arătat o creştere a intensităţii patternului de colorare de la formele bine diferenţiate, cuantificate cu +, spre formele slab diferenţiate, cuantificate cu +++. Această evoluţie anticipează un comportament agresiv al tumorilor.* Putem spune că p_{53} şi-a dovedit valoarea în aprecierea prognosticului pacientelor cu cancer de col uterin.

De asemenea, ***studiul oncogenei p_{53} legat de stadiul bolii*** a evidenţiat că a*socierea dintre procentul p_{53} şi stadiu bolii este statistic semnificativă: aceasta este explicată prin prezenţa unui procent ridicat de cazuri ce prezintă p_{53} + şi sunt în stadii mici ale bolii (I sau II) şi a unui procent ridicat de cazuri ce prezintă p_{53} +++ şi sunt în stadii avansate ale bolii (III sau IV). Valorile lui p_{53} au înregistrat modificări semnificative în funcţie de stadiul bolii. S-a mai evidenţiat şi existenţa unei corelaţii pozitive, puternice şi semnificative între gradul de pozitivitate al p_{53} şi stadiul bolii: astfel, cu cât pozitivitatea p_{53} a fost mai înaltă, cu atât a crescut stadiul bolii şi invers Putem spune că pacientele cu valori crescute ale p_{53} vor avea un prognostic rezervat.*

CONCLUZII

În studiul nostru determinarea imunohistochimică a oncoproteinei BCL-2 nu este un factor predictiv în stabilirea prognosticului cancerului de col uterin.

Faptul că *markerul de prolifirare tumorală Ki67 poate fi considerat un factor de prognostic* este susţinut astfel: cazurile cu malignitate înaltă s-au înregistrat doar în adenocarcinoamele de col uterin; există *o corelaţie pozitivă, puternică şi semnificativă între gradul de malignitate a lui Ki67 şi stadiul bolii (cu cât malignitatea Ki67a fost mai mare, cu atât a crescut şi stadiul bolii şi invers*); valori crescute s-au înregistrat în formele nediferenţiate de neoplasm de col uterin. *Cu cît valorile lui KI67 vor fi mai mari cu atît prognosticul pacientelor va fi mai sever.*

Oncoproteina p_{53} poate fi un factor de prognostic, întrucât valori mari ale markerului au fost determinate la tipul histologic slab diferenţiat şi în stadiile avansate (lll-lV) ale bolii, deci conduce la un prognostic mai sever a pacientelor.

S-a observat o corelaţie pozitivă, puternică şi semnificativă între intensitatea

reacţiei p_{53} cuantificată cu +, ++, +++ şi numărul de nuclei reactivi Ki67, respectiv scorul de malignitate: cu cât pozitivitatea p_{53} a fost mai crescută, cu atât şi malignitatea Ki67 a fost mai înaltă. Putem susţine că, deşi se încadrează în aceeaşi grupă de malignitate, p_{53} +, ++, şi +++ prezintă o relaţie direct proporţională cu procentul de nuclei reactivi Ki67, sugerând probabil gradul de agresivitate tumorală.

GREEN SYNTHESIZED SILVER NANOPARTICLES VIA PLANT EXTRACTS AS ANTI-MELANOMA AGENTS (Abstract): Melanoma is one of the most common and aggressive type of cancer. The actual treatment includes excisional surgery, electrochemotherapy and pharmacotherapy. The pharmaceutical treatment has major drawbacks such as severe side effects and development of drug resistance, fact that orientated the research towards the formulation of new drug delivery systems. Nanocarriers represent an innovative and alternative tool which significantly improves the bioavailability and site-specific targeting of pharmaceutical agents. Due to their biological activities, flexibility and reliability, silver nanoparticles (AgNPs) have gained high attention. The green synthesis of AgNPs, mediated by a plant extract, is an eco-friendly, cheap and effective method. Green synthesized AgNPs have been reported to develop cytotoxic effects against different tumor cell lines. With respect to melanoma, few studies have been conducted until now, but with promising results. The antitumor activity depends on the size and shape of AgNPs and relies on the synergistic effect between phytochemicals and nanocarriers. Overall, green synthesized AgNPs represent a promising strategy for melanoma treatment. **Keywords**: ANTI-MELANOMA, SILVER NANOPARTICLES, GREEN SYNTHESIS, PLANT EXTRACTS.

Melanoma is the most dreadful form of skin cancer and one of the most aggressive cancers in its metastatic forms. Lately, the incidence of melanoma in the developed countries has grown more rapidly than any other type of cancer, especially in the population older than 50 years (1). There are two types of factors that are incriminated for a high risk in the development of skin cancer: genetic and environmental factors (exposure to UV radiation) (2). Other major risk factors for melanoma development include family history, fair pigmentation phenotypes, high numbers of melanocytic nevi (over 50) or the presence of dysplastic nevi, exposure to arsenic and other chemicals (polycyclic hydrocarbons, polyvinylchloride, asbestos) and immunosuppressive drugs (azathioprine, cyclosporine A), viral infections (papillomavirus infections) and tobacco consumption (2, 3). Several molecular mechanisms have been associated with melanoma pathogenesis. They are mainly related to

the oncogenic driver mutations in the major signaling pathways that are involved in apoptosis, proliferation and differentiation of melanocytes, such as ERK/MAP-kinase and PI_3-kinase pathways (tab. I) (4).

TABLE I

Molecular changes associated with melanoma pathogenesis

Molecular event	Outcome
Mutations of BRAF and NRAS genes	activation of ERK/MEK pathways uncontrolled cell proliferation tumor development and growth
Activation of PI3K/AKT	activation of anti-apoptotic β-catenin inhibition of pro-apoptotic BAD melanoma proliferation and metastasis
Inhibition of CDKN2A	activation of CDK4 cell proliferation melanoma uncontrolled growth
Mutations/chromosomal duplications of C-KIT	increase of KIT protein expression alteration of melanocyte proliferation tumorigenesis development
MC1R polymorphisms	increase of susceptibility to melanoma impairment of melanin production increase of UV-induced DNA-mutagenesis
Increase of N-cadherin and VE-cadherin expressions	activation of PI3K-AKT pathway metastasis

BAD, Bcl-2-associated death promoter; BRAF, gene that encodes the protein B-RAF, involved in cell growth; NRAS, gene that encodes the protein N-RAS, involved in the regulation of cell division; CDKN2A, cyclin-dependent kinase inhibitor 2A; CDK4, cyclin-dependent kinase 4; C-KIT, receptor tyrosine kinase protein encoded by the KIT gene; ERK/MEK, extracellular signal-regulated kinase/mitogen-activated protein kinase; MC1R, melanocortin 1 receptor; N-cadherin, VE-cadherin, members of type-1 transmembrane proteins; PI3K, phosphatidylinositol 3-kinase/protein kinase B; AKT, serine/threonine kinase known as protein kinase B.

The excisional surgery, electrochemotherapy, pharmacotherapy and immunotherapy are the main therapeutic approaches in melanoma. The modern pharmacotherapeutics are selected after tumor genotyping process and they mainly include BRAF inhibitors (dabrafenib, vemuranifib), MEK inhibitors (cobimetinib, selumetinib, trimetinib), KIT inhibitors (imatinib) and agents targeting the endoplasmic reticulum stress-associated pathways (ruthenium-derived compounds) (4). These compounds possess a rate of response of approximately 50% and develop a rapid effect. The main disadvantage is the resistance of the melanomic cells which appears after seven months of treatment. Besides, these compounds induce cutaneous toxicities (1, 2).

ERK inhibitors such as GDC-0994 and SCH 772984 are currently in clinical trials. Another therapeutic strategy is related to compounds that target non-coding RNAs such as antisense oligopeptides. The monoclonal antibodies (ipilimumab, pembrolizumab, nivolumab) are recommended in the late stage of metastatic melanoma, advanced or unresectable melanomas but they can lead to autoimmune side effects (4). The severe side effects of the conventional chemotherapeutic or immunotherapeutic agents and the development of drug resistance are the major drawbacks of melanoma pharmacotherapy. The identification of drug delivery systems that can ensure site-specific targeting and optimal bioavailability is an important approach in the development of a successful treatment. Nanostructured materials have attracted considerable attention due to their pleiotropic applications in various fields, such as: electronics, medicine, cosmetics, mechanical engineering, applied physics and chemistry, environmental area, and biotechnology (5, 6, 7). In drug delivery field, nanocarriers represent an important tool to develop formulations that can solve some issues affecting the therapeutic efficacy of antitumor agents, such as poor bioavailability, low therapeutic index, lack of targeting, nonspecific bio-distribution, poor water solubility, and low chemical stability (8, 9). The noble metal nanoparticles are of interest due to their exceptional magnetic, optical, and electronic properties (10). AgNPs and gold nanoparticles (AuNPs) are among the most frequently used nanocarriers due to their flexibility and reliability (11). They also have biological activities and promising results have been reported in antitumor assays. In this review we focused on the potential applications of plant extract synthesized AgNPs in melanoma treatment.

Silver nanoparticles: synthesis and properties

In the nano-sized form (1-100 nm), Ag has unique optical, electronic, thermal, chemical, and biological properties, as well as a high electrical conductivity compared to its macroscopic form (12, 13, 14). The spectrum of AgNPs applications is very wide including pharmaceutical industry (diagnostics, therapeutics, drug delivery), orthopedics, medical device coatings (catheters, dentures, surgical masks), wound dressings, food industry, textile industry, cosmetics, catalysis, optoelectronics, photonics, electronics, and production of household, healthcare-related products and antimicrobial nanopaints (8, 14, 15). The synthesis of AgNPs can be accomplished by physical, chemical, and biological (green synthesis) methods. The physical methods include evaporation-condensation, laser ablation, arc-discharge, energy ball milling technique, and direct current magnetron sputtering (13, 16). Although the physical approaches allow the synthesis of shape-controlled AgNPs, they are highly energy consuming (5). The chemical methods include chemical reduction by using organic and inorganic reducing agents, microemulsion techniques, microwave-assisted synthesis, electrochemical techniques, irradiation-assisted techniques, and pyrolysis (13, 16). The main disadvantage of the chemical approaches is the toxicity of reactants and organic solvents (12).

Both microorganisms (bacteria, fungi and Actinomycetes) and plant extracts have been used in the synthesis of AgNPs (12). There is a growing interest for the green synthesized AgNPs. The green synthesis is eco-friendly, cheap, and gives high yields. Plants are easily available and safe to handle. In addition, plants contain a broad

spectrum of metabolites (polyphenols, terpenoids, alkaloids, proteins, carbohydrates) that might act as reducing agents more efficiently than microorganisms (15, 16). These plant metabolites can ensure the stability and biocompatibility of AgNPs (12). Over 200 plants belonging to different families were screened for green synthesis of metallic nanoparticles (Ag, Au, Fe, and Cu nanoparticles). Among them, AgNPs were the most intensively studied (13). The green synthesis of AgNPs involves a plant extract and a solution of Ag salt. The reaction takes place at room temperature and atmospheric pressure and it is completed within a short period of time (12). The green synthesized AgNPs showed better antimicrobial, antioxidant, and antitumor properties compared to bulk Ag, being very promising for the development of new therapeutic agents (11).

Potential application of green synthesized AgNPs via plant extracts in melanoma treatment

AgNPs showed promising effects against a wide variety of tumor cell lines: U251 human glioblastoma, MDA-MB-231, MCF-7, and T47D human breast adenocarcinoma, HCT15, HT29, and Caco-2 human colon cancer, A549 human alveolar adenocarcinoma, HepG2 hepatocellular adenocarcinoma (11, 14, 17), HeLa human cervical cancer (18), Hep2 human epidermoid larynx carcinoma (19), A375 human melanoma, and B16F10 mouse murine melanoma (14) cell lines. Various plant extracts were used to synthesize AgNPs with antitumor properties. Some examples include extracts isolated from *Vitex negundo* (Chinese chaste tree), *Piper nigrum* (black pepper), *Euphorbia nivulia* (leafy milk hedge), *Annona squamosa* (11), *Origanum vulgare* (oregano), *O. heracleoticum*, *Alpinia katsumadai*, *Ficus sp*., *Mentha arvensis* (corn mint), *Taxus sp*., *Panax ginseng* (true ginseng), *Coriandrum sativum* (coriander) (20). Antitumor efficacy of AgNPs is mediated mainly by upregulation of apoptosis and autophagy, cell cycle arrest, activation of caspases, induction of mitochondrial dysfunction, endoplasmic reticulum stress, oxidative stress, and DNA damage (14). Only a few studies have investigated the antitumor effects of green synthesized AgNPs in melanoma. In these studies, AgNPs were obtained using hydroalcoholic and aqueous extracts from several plant species (tab. II).

Flavonoids were the main constituents of plant extracts that serve as bio reducing and capping agents in the green synthesis of AgNPs. The cytotoxic effects were variable depending on the plant species, chemical composition of extracts, concentration and size of AgNPs. It is well-known the fact that the physicochemical properties of AgNPs (particle shape, size, surface chemistry) but also their concentrations are important parameters that influence the antitumor activity (11). Generally, low concentrations of AgNPs induce antiproliferative effects and smaller nanoparticles cause stronger cytotoxic effects (13).

A potent antimelanoma activity was determined for AgNPs synthesized using extracts from the roots of *Gelsemium sempervirens* (IC_{50}=50 μg/mL) and *Phytolacca decandra* (IC_{50}=78 μg/mL) (21). Also, at 100 μg/mL, AgNPs obtained using extracts from peels and leaves of *Citrus maxima* exhibited a significant cytotoxicity (more than 75%) in B16F10 mouse melanoma cells (27). Several mechanisms of AgNPs-induced cytotoxicity in melanoma cell lines have been described,

such as: induction of apoptosis, up-regulation of autophagy, DNA breakage, chromatin condensation, activation of caspase-3 and endonucleases, as well as cell cycle arrest. Caspase-3 plays an important role in the cascade of reactions that induces apoptosis. Endonucleases are enzymes involved in the DNA fragmentation at the internucleosomal linker regions (21, 27).

It has been suggested that the antiproliferative activity of green synthesized AgNPs is based on the synergism between plant constituents and Ag (21). Numerous studies proved the chemo preventive and antitumoral potential of different flavonoids and flavonoid-rich extracts in melanoma. Flavonoids act by targeting different pathways, immune and inflammatory responses involved in melanoma pathogenesis. Thus, flavonoids like apigenin inhibit the signal transducer and activator of transcription (STAT) and AKT pro-survival signaling and activate ERK pro-apoptotic signaling pathways. Kaempferol has an inhibitory activity on ribosomal S6 kinase and stress activated protein kinase (MSK1), which were found to be overexpressed in human squamous cell carcinomas (28). Also, triterpenoids such as oleanolic acid from *Phytolaccca decandra* showed cytotoxic effects in melanoma cells. Oleanolic acid displays antiproliferative effects by suppression of epidermal growth factor receptor (EGFR) activity and inducing mitochondria-dependent caspase 3-mediated apoptosis in A375 human skin melanoma cells (29). It is obvious that the constituents of plant extracts can functionalize silver nanoparticles enhancing their antitumor activity.

TABLE II

The anti-melanoma effects of green synthesized AgNPs

Plant species	Extract	Reducing and capping agents	AgNPs		Cell line	IC_{50} (µg/mL)	Outcome	Ref.
			Size (nm)	Shape				
Phytolacca decandra, Phytolaccaceae, pokeweed	ethanolic, 70%, v/v	flavonoids triterpenes	90.87	spherical	A375	78	antiproliferative activity, apoptosis, activation of caspase 3, cell cycle arrest, DNA fragmentation	21, 22
Gelsemium sempervirens, Gelsemiaceae, yellow jessamine	ethanolic, 70%, v/v	flavonoids alkaloids	112.2	spherical	A375	50		21, 23
Hydrastis canadensis, Ranunculaceae, orangeroot	ethanolic, 70%, v/v	flavonoids alkaloids	111.3	spherical	A375	80		21, 24
Thuja occidentalis, Cupressaceae, northern white cedar	ethanolic, 70%, v/v	flavonoids terpenes	122.8	spherical	A375	120		21,25
Butea monosperma, Fabaceae, flame of forest	aqueous	chalcones flavonoids	20-80	spherical	B16F10	-	no cytotoxicity	26
Citrus maxima, Rutaceae, pomelo	aqueous	flavonoids polyphenolic acids tannins terpenes	2-50	spherical	B16F10	-	oxidative stress, apoptosis, cell cycle arrest	27

CONCLUSIONS

Although the available data fail to define the whole picture of bioactivity of green synthesized AgNPs in melanoma, the results of up to date studies are very promising. The identification of plant extracts having potent intrinsic antitumor properties and being able to generate easily AgNPs with high stability and biocompatibility could be one of the successful approaches to develop new anti-melanoma agents. Also, more research is needed to evaluate the overall impact of AgNPs on human health.

EVALUATION OF LIFE QUALITY IN PATIENTS WITH CERVICAL CANCER WITH HOLISTIC APPROACHES PSYCHOLOGICAL AND MEDICAL (Abstract): Assessment of quality of life requires a multidimensional measurement of health and wellness, as reported by the patient. The central objective of this research was to capture the phenomenon of impact on cancer diagnosis; disease and treatment have on physical and emotional status of patients with cervical cancer. **Material and method**: The study was realized on a group of 70 patients diagnosed with this disease, aged 25-55 years and from different intellectual categories both in rural and urban. We used an experimental design of type 2 (early disease stage/advanced) x 5 (surgical therapeutic method / surgery with radiotherapy / surgery with chemotherapy / surgery with radiotherapy and chemotherapy / palliative) x 2 (low therapeutic compliance / high) x 2 (low depression / high). As data collection instruments were used histopathological examinations and psychological tests (to measure quality of life SF-36 test and test sensory and affective pain McGill and independent variables Beck Depression Scale and IPQ-R), and to verify hypotheses T test for independent samples and comparing Univariate ANOVA. **Results**: The results showed the importance of emotional state on the development of cancer disease and its quality of life. **Key words**: QUALITY OF LIFE, CERVICAL CANCER, ILLNESS PERCEPTIONS, DEPRESSION, CHEMORADIOTHERAPY

Valoarea oricărei intervenţii, incluzându-i în mod direct pe bolnavii cu cancer, este determinată judecând impactul atât asupra numărului de ani de viaţă câştigaţi cât şi al calităţii vieţii. Acest impact, măsurat din punctul de vedere al costului, determină o anumită valoare. Calitatea vieţii ridică numeroase probleme şi creează suficiente dezbateri. Din punct de vedere istoric timpul de supravieţuire a fost cel mai util indicator de măsurare al eficacităţii tratamentului. Recunoscând că problema timpului, fără calitate are o valoare discutabilă, cercetătorii din domeniul oncologic au avut tendinţa să presupună că adăugarea de timp în supravieţuire ar însemna şi un plus de valoare pentru pacienţii oncologici, deşi în mod frecvent acest lucru nu este întotdeauna adevărat, în special atunci când toxicitatea tratamentului şi efectele întârziate ale acestuia nu sunt luate în considerare. În prezent, prin disponibilitatea recentă a chestionarelor care vizează calitatea vieţii, este oportun a se măsura cele trei dimensiuni: starea de bine fizică, psihică şi socială alături de cantitatea ei. Acest lucru ne permite să

spunem doar că, timpul adăugat de unele tratamente este de o valoare suficientă pentru a justifica costurile lor şi că s-ar impune analiza valorii unor terapii care adaugă timp pentru prelungirea vieţii, dar nu şi a calităţii acesteia. Partea critică a acestui lucru este că nu întotdeauna se poate alege între toleranţa la tratament (efectele lui secundare) şi timpul de supravieţuire ; uneori, un tratament temporar, paleativ al cancerului poate evita simptome greu de suportat, însă fără a prelungi supravieţuirea. Pacienţii pot găsi acest lucru dezirabil chiar şi în faţa competiţiei cu toleranţa. Numai o evaluare atentă, raportată la calitatea vieţii lor, poate permite aprecierea acestor compromisuri, între simptomele relatate şi toxicitate (1).

OBIECTIVE DE LUCRU

Pornind de la premisa că între pacientele cu o dispoziţie afectivă negativă ridicată şi cele cu dispoziţie afectivă negativă scăzută există o diferenţă în ceea ce priveşte calitatea vieţii acestora, am încercat să realizăm o cercetare în care am dorit să stabilim relaţiile între variabilele investigate şi în ce măsură evoluţia unei variabile influenţează celorlalte variabile. Am considerat că este important de evidenţiat stadializarea bolii, a metodei terapeutice urmate de paciente şi implicaţiile acestor proceduri folosite în scop terapeutic asupra dispoziţiei lor afective negative, iar nu în ultimul rând importanţa autocontrolului pacientelor cu cancer de col uterin precum şi percepţia acestora în controlul tratamentului.

Studiul urmăreşte evidenţierea impactului cancerului de col uterin asupra calităţii vieţii pacientelor diagnosticate cu această afecţiune şi a factorilor ce conduc la scăderea calităţii vieţii acestora.

Obiectivele urmărite au fost :

1. Evaluarea influenţei metodei terapeutice asupra stării de sănătate fizică, mentală şi durere.
2. Aprecierea ponderii în care autocontrolul şi controlul tratamentului (complianţa la tratament) influenţează starea de sănătate fizică, mentală şi durerea.
3. Influenţa depresiei asupra stării de sănătate fizică, mentală şi durerii.
4. Înregistrarea unor posibile efecte de interacţiune între stadiul bolii şi depresie, cu consecinţe asupra calităţii vieţii pacientelor cu cancer de col uterin.
5. Cercetarea relaţiei dintre stadiul bolii şi complianţa la tratament, cu importanţă asupra calităţii vieţii pacientelor.

MATERIAL ŞI METODĂ

Pentru a aprecia dacă există diferenţe între grupele de paciente studiate s-a efectuat un studiu transversal, care are ca scop evaluarea diferitelor nivele de durere, de depresie, stare de sănătate fizică şi mentală, stadializare, metodă terapeutică, complianţă la tratament, investigând fiecare subiect (2). Colectarea datelor s-a realizat pe o perioadă de 3 ani (2007 – 2010). Au fost selecţionate diferite grupe în funcţie de aceste variabile, pacientele fiind aflate atât în evidenţa Spitalului Clinic Militar de Urgenţă „Dr. Iacob Czihac" Iaşi, cât şi a Maternităţii „Cuza-Vodă" Iaşi. Subiecţii au fost evaluaţi cu ajutorul instrumentelor de măsurare a variabilelor alese în studiu o singură dată, respectiv la un interval de 3 luni de zile de la intervenţia chirurgicală, sau de la diagnosticare – pentru cele care au ales sa urmeze doar metoda paleativă, iar apoi am verificat în ce măsură aceste variabile se influenţează reciproc.

Lotul de subiecţi a fost alcătuit dintr-un număr de 70 paciente diagnosticate - în urma examenului clinic preoperator coroborat cu examenul histopatologic pre- şi postoperator (aspectele anatomo-patologice tumorale – macroscopia, microscopia şi stadiul patologic) - cu cancer de col uterin, aflate în diferite stadii ale bolii. Pacientele cuprinse în cercetare au avut vârsta cuprinsă între

25-55 ani, de categorii sociale diferite şi provenind atât din mediul rural cât şi din cel urban. O parte dintre subiecţi au beneficiat atât de tratamentele complexe ale cancerului de col uterin (chirurgical cu radioterapie şi chimioterapie), altele au urmat tratamente parţiale (numai chirurgicale, ori chirurgicale cu radioterapie, chirurgicale cu chimioterapie) sau numai tratament paleativ. De asemenea, stadializarea bolii a fost cea decisivă în privinţa recomandării procedurii terapeutice ulterioare pe care pacientele urmau să o efectueze.

S-au utilizat ca instrumente de culegere a datelor testele psihologice (pentru măsurarea calităţii vieţii s-a folosit chestionarul SF-36 şi chestionarul McGill pentru măsurarea durerii senzoriale şi afective ; pentru măsurarea variabilelor independente – Scala de depresie Beck şi Illness Perception Questionnaire R), iar pentru verificarea ipotezelor Testul T pentru compararea eşantioanelor independente, pentru a analiza influenţa variabilelor independente asupra celor dependente şi, de asemenea, ANOVA Univariată, cu interesarea efectelor principale ale variabilelor, cât şi efectele de interacţiune ale acestora. Întreaga metodologie utilizată în cercetare a fost adaptată, şi validat pe populaţia românească. S-au calculat mediile (M) scorurilor obţinute de paciente la testele aplicate, valorile Testului Levene (F) pentru verificarea egalităţii varianţelor, diferenţele dintre medii cu aflarea gradelor de libertate (df) şi a pragului de semnificaţie (p), precum şi Testul de Contrast (Difference) pentru compararea diferitelor grupuri de paciente rezultate din împărţirea lor în funcţie de categoriile variabilelor independente, iar în cazul variabilei ‚metoda terapeutică' Testul Post Hoc Bonferroni. S-a considerat testele statistice ca fiind semnificative dacă pragul de semnificaţie, p, a fost mai mic sau cel mult egal cu valoarea 0,05 (pentru un interval de încredere de 95%).

REZULTATE

1. Pentru realizarea primului obiectiv s-a analizat dacă metoda terapeutică influenţează starea de sănătate fizică, mentală şi durerea. În urma comparării rezultatelor a câte două categorii privind metoda terapeutică 1 (chirurgicală), 4 (chirurgicală + radioterapie + chimioterapie) şi 5 (tratament paleativ) urmată de paciente, am obţinut următoarele date :

a) media scorurilor obţinute pentru starea de sănătate fizică şi mentală :

- *la pacientele care au urmat metoda terapeutică chirurgicală, M=114,40, iar la pacientele care au urmat metoda terapeutica chirurgicală cu radioterapie şi chimioterapie, M=105 ;* F = 47,25 ; p< 0,001 ; t (18) = 30,76 ; p <0,001.
- *la pacientele care au urmat metoda terapeutică chirurgicală cu radioterapie şi chimioterapie, M=105, iar la pacientele care au urmat metoda terapeutică paleativă, M=67,30 ;* F = 647 ; p<0,001 ; t (28) = 14,03 ; p <0,001.

b) media scorurilor obţinute pentru durerea senzorială şi afectivă :

- *la pacientele care au urmat metoda terapeutică chirurgicală, M=8,70, iar la pacientele care au urmat metoda terapeutică chirurgicală cu radioterapie şi chimioterapie, M=7 ;* F = 34,63 ; p < 0,001 ; t (9) = 4,63 ; p = 0,001.
- *la pacientele care au urmat metoda terapeutică chirurgicală cu radioterapie şi chimioterapie, M=7, iar la pacientele care au urmat metoda terapeutica paleativă, M=36,5 ;* F = 51,43 ; p < 0,001 ; t (19) = 51,43 ; p < 0,001.

2. În urma aprecierii ponderii în care autocontrolul şi controlul tratamentului (complianţa la tratament) influenţează starea de sănătate fizică şi mentală şi durerea, se remarcă următoarele :

a) media scorurilor obţinute pentru starea de sănătate fizică şi mentală : la pacientele care au prezentat un control per-

sonal şi al tratamentului scăzut, M=61,80, iar la pacientele cu un control personal şi al tratamentului crescut, M=99,88 ; F = 25,52 ; p < 0,001 ; t (65,90) = 15,92 ; p < 0,001.

b) media scorurilor obţinute pentru durerea senzorială şi afectivă : la pacientele cu un nivel scăzut al complianţei terapeutice, M=31,85, iar la pacientele cu o complianţa crescută,M=16,18 ; F = 39,86 ; p < 0,001 ; t (57,64) = 8,24 ; p < 0,001.

3. În ceea ce priveşte influenţa depresiei asupra stării de sănătate fizică, mentală şi durerea s-au constatat următoarele rezultate :

a) media scorurilor obţinute pentru starea de sănătate fizică şi mentală : la pacientele care au prezentat un nivel al depresiei scăzut, M=106,94, iar la pacientele cu un nivel crescut al depresiei, M=70 ; F = 6,38 ; p = 0,001 ; t (59,13) = 15,52 ; p < 0,001.

b) media scorurilor obţinute pentru durerea senzorială şi afectivă : la pacientele care au prezentat un nivel al depresiei scăzut, M=9,25, iar la pacientele cu un nivel crescut al depresiei, M=32,72 ; F = 0,16 ; p > 0,05 ; t (68) = 17,81 ; p < 0,001.

4. Înregistrarea unor posibile efecte de interacţiune între stadiul bolii şi depresie asupra calităţii vieţii pacientelor cu cancer de col uterin a evidenţiat următoarele rezultate :

a) influenţa stadiului bolii asupra stării de sănătate fizică şi mentală : F (1,69) = 5,25 ; p = 0,02 ; media scorurilor obţinute la pacientele aflate în stadiul 1-2 al bolii, M = 90,35, iar la pacientele aflate în stadiul 3-4 al bolii, M = 85,29 ; p = 0,025 ; ***influenţa depresiei asupra stării de sănătate fizică şi mentală*** : F (1,69) = 278,19 ; p < 0,001 ; media scorurilor obţinute la pacientele cu un nivel scăzut al depresiei, M = 106,22, iar la pacientele cu un nivel crescut al depresiei, M = 69,41 ; p < 0,001 ; ***efectul de interacţiune a stadializării bolii şi depresiei asupra stării de sănătate fizică şi mentală*** : F (1,69) = 980,11 ; p = 0,001 : ***efectul stadializării bolii la fiecare nivel al depresiei :*** în grupul pacientelor cu un nivel scăzut al depresiei, media scorurilor obţinute la pacientele aflate în stadiul 1-2 al bolii este M = 112,70, iar la pacientele aflate în stadiul 3-4 este M= 99,75 ; t (34) = 7,19 ; p < 0,001 ; în grupul pacientelor cu un nivel ridicat al depresiei, media scorurilor obţinute la pacientele aflate în stadiul 1-2 al bolii este M = 68, iar la pacientele aflate în stadiul 3-4, este M = 70,83 ; t (32) = 1,01 ; p > 0,05 (0,321) *;* ***efectul depresiei la fiecare nivel al stadializării bolii :*** în grupul pacientelor aflate în stadiul 1-2 al bolii, media scorurilor obţinute la pacientele cu nivelul depresiei scăzut este M = 112,70, iar la pacientele cu un nivel crescut al depresiei, M= 68 ; t (28) = 83,68 ; p < 0,001 ; în grupul pacientelor aflate în stadiul 3-4 al bolii, media scorurilor obţinute la pacientele cu un nivel al depresiei scăzut este M = 99,75, iar la pacientele cu un nivel ridicat al depresiei, este M = 70,83 ; t (38) = 8,81 ; p < 0,001, (fig. 1,2).

b) influenţa stadiului bolii asupra durerii senzoriale şi afective : F(1,69) = 15,70 ; p <0,001 ; media scorurilor obţinute la pacientele aflate în stadiul 1-2 al bolii este M = 18,17, iar la pacientele aflate în stadiul 3-4 al bolii, M = 23,16, p <0,001 ; ***influenţa depresiei asupra durerii senzoriale şi afective*** : F (1,69) = 311,81 ; p < 0,001 ; media scorurilor obţinute la pacientele cu un nivel scăzut al depresiei este M = 9,55, iar la pacientele cu un nivel crescut al depresiei, M = 31,79, p<0,001 ; ***efectul de interacţiune a stadializării bolii şi depresiei asupra durerii*** : F (1,69) = 0,105 ; p = 0,747 : ***efectul stadializării bolii la fiecare nivel al depresiei :*** în grupul pacientelor cu un nivel scăzut al depresiei, media scorurilor obţinute de pacientele aflate în stadiul 1-2 al bolii la durere este M = 6,85, iar la pacientele aflate în stadiul 3-4, M= 12,25 ; t (34) = 2,29 ; p = 0,008 ; în grupul pacientelor cu un nivel ridicat al depresiei, media sco-

< 0,001 ; în grupul pacientelor cu un nivel ridicat al complianţei, media scorurilor obţinute de pacientele aflate în stadiul 1-2 al bolii este M = 6,85, iar la pacientele aflate în stadiul 3-4, M = 22,40 ; t (48) = 6,31 ; p < 0,001 ; ***efectul complianţei terapeutice la fiecare nivel al stadializării bolii :*** în grupul pacientelor aflate în stadiul 1-2 al bolii, media scorurilor obţinute la durere de pacientele cu nivelul complianţei scăzut este M =29,50, iar la pacientele cu un nivel crescut al complianţei, M= 6,85 ; t (28) = 23,45 ; p < 0,001 ; în grupul pacientelor aflate în stadiul 3-4 al bolii, media scorurilor obţinute de pacientele cu un nivel al complianţei scăzut este M = 34,20, iar la pacientele cu un nivel ridicat al complianţei, M = 22,40 ; t (38) = 17,93 ; p < 0,001, (fig. 7,8).

DISCUŢII

În cazul tratamentului pentru cancerul de col uterin, oboseala, care este un factor de scădere a stării de sănătate fizică şi mentală şi care, de altfel, a fost măsurat în studiu, se asociază mai frecvent radioterapiei şi chimioterapiei ; în schimb, după aplicarea doar a intervenţiei chirurgicale fie diagnostice, fie terapeutice, oboseala tinde să dispară în timp ; nu se întâmplă acest lucru în cazul terapiilor combinate ; chimioterapia are cele mai multe inconveniente dintre toate tratamentele din cauza numeroaselor efecte secundare, deşi ele pot varia de la individ la individ şi într-un oarecare grad ; s-a observat că pe termen mai lung durerea la pacientele tratate chirurgical a scăzut semnificativ comparativ cu durerea preoperatorie, în schimb dacă tratamentul cancerului nu a fost continuat, aceasta a recidivat în intensitate şi frecvenţă (3,4) ;

Complianţa la tratament este legată mai ales de percepţia de către pacientă a stării ei de boală, de atitudinea faţă de tratament şi de conştientizarea bolii, de costurile medicamentelor, efectele secundare ale tratamentului şi tratamentul inadecvat al simptomelor de boală (5) ; convingerile personale despre durere pot fi predictive pentru nivelul durerii percepute de paciente, suferinţele emoţionale şi credinţa că durerea semnalează o înrăutăţire a stării de sănătate au reprezentat predictori ai raportării durerii ; complexitatea tratamentului a putut fi un factor cu influenţă directă asupra aderenţei terapeutice, o influenţă negativă fiind determinată de numărul mare de medicamente, dozele frecvente, durata lungă a tratamentului, efecte secundare numeroase şi forme diferite de administrare ; aderenţa terapeutică este cu atât mai mică cu cât remisiunea bolii este de durată mai lungă ; în toate cazurile, beneficiile terapeutice trebuie să contra-balanseze

disconfortul (cu cât este mai mare beneficiul perceput, cu atât e mai mare dorinţa de a tolera un oarecare disconfort) ;

Prin progresia cancerului, apariţia durerilor se asociază cu simptome depresive mai severe, în timp ce depresia comorbidă se asociază cu diminuarea funcţionării şi o calitate a vieţii mai scăzută (6) ; cele mai multe complicaţii depresive au apărut cu probabilitate mai mare la pacientele cu durere şi invers (7) ;

Cele mai mici scoruri la starea de sănătate fizică şi mentală au fost obţinute de pacientele aflate în stadiul incipient al bolii (1-2) dar cu un nivel ridicat al depresiei, ceea ce demonstrează influenţa nu atât a stadializării bolii cât mai important a depresiei asupra calităţii vieţii ; rezultatele acestora sunt comparative cu cele ale pacientelor aflate în stadiul 3-4 şi cu depresie ridicată, care au obţinut scoruri mici la calitatea vieţii, dar diferenţe semnificative nu există între aceste două grupe de paciente.

Este o mare diferenţă între problemele cu care se confruntă şi trebuie să le facă faţă o bolnavă cu o leziune incipientă la nivelul colului uterin, faţă de alta, cu o tumoră invazivă, cu posibile metastaze, aici fiind vorba de un stres particular asociat diagnosticului care poate influenţa reacţia la problemele cu care se confruntă, implicit starea psihică ; s-au întâlnit în clinică paciente cu tumori în stadiu incipient având şanse mari de vindecare, dar care au reacţionat cu neîncredere faţă de eficacitatea tratamentului, prin stare depresivă şi senzaţie de neputinţă şi lipsă de speranţă, în timp ce bolnave aflate în stadii avansate, cu un prognostic mai rezervat, s-au angajat să-şi asume boala, iar între curele terapeutice s-au străduit să ducă o viaţă cât mai apropiată de cea dinaintea îmbolnăvirii (8) ;

Cele mai mici scoruri la starea de sănătate fizică şi mentală le-au obţinut pacientele aflate în stadiul 3-4 al bolii şi cu un nivel scăzut al controlului personal şi al tratamentului, iar cele mai bune scoruri - cele aflate în stadiul 1-2 al bolii, cu un autocontrol şi control al tratamentului ridicat ; între cele două grupe de paciente, unele aflate în stadiul 1-2 al bolii, iar altele în stadiul 3-4, diferenţele semnificative în ceea ce priveşte starea de sănătate fizică şi mentală au fost date de modul în care aceste paciente şi-au gestionat autocontrolul şi s-au adaptat tratamentului oncologic recomandat.

Analizând grupul pacientelor aflate în aceleaşi stadii ale bolii, diferenţele semnificative pentru scala durerii sunt date de gradul lor de aderenţă la tratamentul oncologic ; pacientele cu o încredere în sine extrem de puternică au exprimat scepticism faţă de cadrele medicale ; în schimb pacientele care au dezvoltat un control ridicat personal au fost mai puţin deprimate, mai puţin ostile şi s-au adaptat mai bine din punct de vedere psihosocial decât cele cu un control scăzut ; aşteptările negative privind boala au fost asociate cu mai multe complicaţii în timpul spitalizărilor şi cu o probabilitate mai mare de a dezvolta episoade de depresie ; dacă pacientele au înţeles scopul tratamentului şi motivul precis al administrării medicamentelor, s-a obţinut un grad superior de aderenţă ; cel mai important factor de influenţare a complianţei ar fi nu neapărat stadializarea bolii, cât perceperea de către pacientă a interesului acordat de către medic, aceasta fiind ameliorată atunci când îi sunt oferite explicaţii clare, încurajare, susţinere şi o urmărire sistematică a evoluţiei.

CONCLUZII

Pacientele care au urmat doar metoda chirurgicală au prezentat un nivel al stării de sănătate fizică şi mentală, precum şi un nivel al durerii semnificativ crescut comparativ cu a celor care au urmat metoda chirurgicală + radioterapie + chimioterapie. Pacientele care au urmat doar metoda paleativă au prezentat un nivel al stării de sănătate fizică şi mentală semnificativ scă-

zut comparativ cu a celor care au urmat metoda terapeutică complexă ; apar diferenţe semnificative şi între nivelul durerii la pacientele care au urmat metoda terapeutică complexă şi celor care au urmat doar un tratament paleativ ; pacientele care au urmat metoda chirurgicală complexă au prezentat un nivel al durerii semnificativ scăzut comparativ cu a celor care au urmat doar terapia paleativă.

Pacientele care au prezentat un control personal şi al tratamentului crescut au prezentat un nivel al stării de sănătate fizică şi mentală semnificativ crescut şi un nivel al durerii semnificativ scăzut comparativ cu a celor cu un grad redus al complianţei. Pacientele cu un nivel al depresiei crescut au prezentat un nivel al stării de sănătate fizică şi mentală semnificativ scăzut şi un nivel al durerii semnificativ crescut comparativ cu pacientele care au avut un nivel al depresiei scăzut.

Pacientele aflate în stadiul 1-2 al bolii şi cu un nivel redus al depresiei au prezentat un nivel al stării de sănătate fizică şi mentală semnificativ crescut decât pacientele aflate în stadiul 3-4 al bolii ; în schimb nu există diferenţe semnificative între nivelul stării de sănătate fizică şi mentală la pacientele cu un nivel crescut al depresiei, indiferent de stadiul bolii. Pacientele aflate în stadiul 3-4 al bolii şi cu un nivel redus al depresiei au prezentat un nivel al stării de sănătate fizică şi mentală semnificativ mai mare comparativ cu cele cu un nivel crescut al depresiei ; în ceea ce priveşte durerea, pacientele aflate în stadiul 1-2 al bolii şi cu un nivel redus al depresiei au prezentat un nivel al durerii afective şi senzoriale semnificativ scăzut comparativ cu pacientele aflate în stadiul 3-4 al bolii.

Pacientele aflate în stadiul 1-2 al bolii şi cu un nivel redus al controlului personal şi autocontrolului au prezentat un nivel al stării de sănătate fizică şi mentală semnificativ mai mare decât pacientele aflate în stadiul 3-4 al bolii. Pacientele aflate în stadiul 1-2 al bolii şi cu un nivel redus al controlului personal şi autocontrolului au prezentat un nivel al durerii semnificativ mai mic decât pacientele aflate în stadiul 3-4 al bolii ; nivelul durerii a crescut invers proporţional cu nivelul autocontrolului şi controlul tratamentului.

THE EVALUATION OF SOME ANTIBACTERIAL DRUGS INFLUENCE ON EXPERIMENTAL-INDUCED ACUTE INFLAMMATION IN RATS (Abstract): In present study we aimed to investigate the effects of some antibiotics on carrageenan-induced rat paw inflammation. **Material and methods:** The experiment was performed on white male Wistar rats, randomly distributed into 7 groups of 6 rats each. The animals were treated intraperitoneally with saline solution, prednisone (PDN), indomethacin (IND); cefotaxime (CEF), gentamicin (GEN) and sulfamethoxazole (SMT), 30 minutes before carrageenan sub-plantar injection. Control group contains rats with intra-paw injection of saline. Prednisone and indomethacin were administered in a single daily injection, and the antibiotics every 12 hours, for 3 days. The paw volume was assessed plethysmographycally before, and 1, 3, 6, 24 and 72 hours after the administration of carrageenan. We studied the effects of the tested antibiotics in acute inflammation, by evaluating their influence on leukocyte formula, erythrocyte sedimentation rate and fibrinogen levels, before and at 3, 24 and 72 hours in the study. Experimental protocol was implemented according our University Committee for Research and Ethical Issues guidelines. **Results**: The treatment with CEF, GEN, SMT was associated by an important suppression of the edema development, in all time moments of the investigation, but less intense than those of PDN and IND. **Conclusions:** CEF manifested the most potent anti-inflammatory activity, compared to GEN and SMT at 3 hours and 6 hours in this acute of paw`s inflammation test. **Keywords:** CEFOTAXIME, GENTAMICIN, SULFAMETHOXAZOLE, CARRAGEENAN, RAT.

Inflammation is an essential part of the body's immune response. It is the organism's attempt to heal after an injury; to protect against foreign invaders such as viruses, bacteria or fungi; but also repairing damaged tissues (1). The inflammatory response is a defense mechanism that has evolved to the organs to protect them from infection and wound. Its purpose is to locate and remove the harmful agent, to eliminate the damaged tissue components, helping the organism`s healing process. The response consists of changes in blood flow, an increase in vessels permeability, the

migration of fluids, proteins, and leukocytes from the circulation to the tissue lesion (1, 2). An inflammatory response lasting only a few days is called acute inflammation, while a continuing response is defined as chronic inflammation.

For many years, it has been thought that acute and chronic inflammatory processes have different causes, with the involvement of various cells and numerous mediators of inflammation, which could be responsible for distinct clinical manifestations. Over time, however, several hypotheses have been suggested, among which, a more modern vision postulates, that these processes would be interconnected. Moreover, in the evolution of acute inflammation, tissue healing processes may progress in another direction and lead to the development of a chronic inflammatory state, in which fibrotic changes predominate (4). Acute inflammation has a rapid onset and immediately becomes severe. Signs and symptoms are present for only a few days, but in some situations, inflammation may persist for several weeks. A series of biochemical events propagate and contribute to the evolution of the inflammatory response, involving the local vessels, the immune system, and various cells in the wound tissue. As characteristic elements of acute inflammatory process are mentioned: the protein exudate and the presence of neutrophils (5, 6). Chronic inflammation has a prolonged evolution for several months or even years. Continued inflammation leads to a progressive change in the type of cells present at the site of inflammation, such as mononuclear cells, and is characterized by simultaneous destruction and tissue healing. As characteristic elements of chronic inflammation are considered: the presence of macrophages and lymphocytes, few neutrophils; blood vessel proliferation, fibrosis and tissue necrosis (2, 6).

The current trend involves the performing of multiple researches, to evaluate the influence of antibiotics on the mediators of inflammation, on the body`s immune defense parameters and on the mechanisms responsible for oxidative stress. All these investigations include complex studies to define the pathophysiological mechanisms involved, the evolution, consequences on the body, and to find new methods for the prevention and treatment of infectious diseases.

The analysis of data obtained from the experimental researches, will open up the prospects of completing, theoretical and practical information about the influence of antibacterial chemotherapies on the acute inflammatory markers.

We aimed to investigate the effects of some antibacterial chemotherapeutic agents (from the groups of cephalosporins, aminoglycosides, sulfonamides) on carrageenan-induced rat paw inflammation.

MATERIAL AND METHODS

White male Wistar rats (200-250 g) purchased from the bio-base of "Grigore T. Popa" University of Medicine and Pharmacy from Iasi, were used for the researches.

The animals were randomly distributed into 7 groups of 6 rats each, according to the following protocol: Group 1 (Control): rats with intra-paw injection of saline - control group without inflammation. For the following groups, carrageenan-induced paw inflammation was induced. Group 2 (SS): saline solution - 0.3 ml/100g body – control group with inflammation; Group 3 (PDN): prednisone 5 mg/kg b.w. /day; Group 4 (IND): indomethacin 150 mg/ kg b.w. /day; Group 5(CEF): cefotaxime 200 mg/ kg b.w. /day; Group 6 (GEN): gentamicin 20 mg/ kg b.w. /day; Group 7 (SMT): sulfamethoxazole 250 mg/ kg b.w. /day. The substances used in the experi-

ment were purchased from Sigma-Aldrich Chemical Co. Germany.

In order to familiarize with the experimental environment, the animals were housed for 7 days in laboratory, under standard conditions (constant temperature of 21 ± 2°C, relative humidity of 50-70% and alternating illumination regimen, with a light/dark ratio of 12 hours/12 hours). Rats received granulated diet and water *ad libitum* except of the day of investigations. To avoid the chronobiological influences, experimental researches were performed in the interval between 8.00-13.00 a.m.

The animals were treated intraperitoneally with the tested substances, 30 minutes before 1% carrageenan sub-plantar injection, and for 3 consecutive days. Two known anti-inflammatory drugs have been used as positive control substances, in the experiment: prednisone (corticosteroid with marked anti-inflammatory and immunosuppressive effects) and indomethacin (non-steroidal anti-inflammatory with strong anti-inflammatory effects), in a single daily injection, for 3 days. The antibiotics were administered every 12 hours, for 3 days.

Study design

Carrageenan-induced acute paw inflammation model

The experimental induced paw inflammation (using carrageenan, oil of turpentine), is a standardized and internationally recognized model of acute inflammation, being an easy and convenient method for studying the anti-inflammatory effects of different substances, the evaluation being based on their ability to prevent or reduce the development of the animal`s paw inflammatory process (7,8). The local subcutaneous injection of 0.2 ml 1% carrageenan solution, on the rat`s paw, induces a biphasic response: an immediate inflammatory reaction and neurogenic pain, lasting for 6 hours, and a late response phase (inflammatory hyperalgesia), with a maximum intensity after 72 hours, that gradually decreases over time to 96 hours (9).

Plethysmometer assessment

The paw volume was measured before injection of the chemical agent (at baseline), 1 hour, 3 hours, 6 hours, 24 hours and 72 hours after the inducing of inflammation, using a Digital Water Plethysmometer (PanLAB Apparatus).

Blood tests

Under general anesthesia with isoflurane, blood samples (2 ml) were collected from the rat`s retro-orbital plexus and hematological determinations were performed before inflammation, as well as, after 3 hours, 24 hours and 72 hours in the experiment. Using the ACCENT 200 Analyzer, the leukocyte formula was determined. Measurement of erythrocyte sedimentation rate (ESR) was performed by micro capillary technique in EDTA (ethylene-di-amine tetra-acetic acid) anti-coagulated blood. The whole fibrinogen levels were assessed by coagulometry method in citrated venous blood. The both ESR and the acute-phase protein fibrinogen were considered to be markers of inflammatory reaction. The evaluation of ESR value is a nonspecific test for inflammation assessing indirectly its presence and evolution. It is well known that, ESR, as well as fibrinogen raise in response to inflammatory processes.

Data were centralized and statistically processed using the t-student test and analysis of variance (ANOVA) method for *Microsoft Office Excel* 2010. The results were expressed as arithmetic mean of values ± the standard deviation (SD). The p-values (representing the probability), lower than the 0.05 and 0.01 levels were considered to be statistically significant, respec-

tively very significant, comparing with control group.

The experimental protocol was approved by the Ethic Committee on Research of "Grigore T. Popa" University of Medicine and Pharmacy, Iasi, Romania, in concordance with EU Directive 2010/63/EU, regarding the handling of laboratory animals (10, 11).

RESULTS

The statistical analysis of the data revealed that, intra-paw administration of carrageenan 1%, induced local acute inflammation, manifested by an increase in rat paw volume, statistically significant comparing with baseline volume. The local pain was suggested by flinching and licking of the injected paw, redness and swelling of inflamed paw were observable in direct examination.

Inflammation has progressively developed, with a maximal intensity at 6 hours, after which it has slowly diminished, being persistent for 72 hours, in the experiment. These results are consistent with the data communicated in the literature, about the evolution of carrageenan paw edema in rats (12, 13). No evidence of acute inflammatory manifestations, nor significant changes in paw volume and skin color, have been observed, in control group with intra-paw injection of saline solution.

The administration of PDN and IND determined a substantial inhibition of the paw local edema, evidenced in all time points of testing, after the administration of carrageenan. These observations are in accordance with the literature data, regarding the effects of different non-steroidal anti-inflammatory drugs, in the experimental model of carrageenan-induced paw inflammation in rats (14, 15, 16). For CEF, GEN, SMT groups, an important suppression of the local inflammation, was observed, at all the moments at which paw edema was evaluated.

The use of PDN resulted in the most accentuated diminution of the paw volume, statistically significant compared to control group with local inflammation. The weakest reduction in the volume of the inflamed paw, was induced by SMT. The effects of the tested substances on the decreasing of paw edema volume, were in the descending order, the following: PDN > IND > CEF > GEN> SMT (fig. 1).

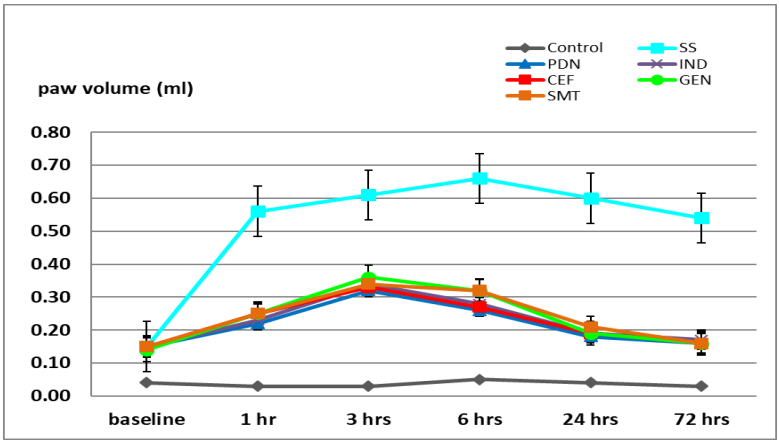

Fig. 1. The effects of CEF, GEN and SMT on carrageenan-induced paw inflammation in rats. Each point represents the mean ± S.D. of paw volume for 6 animals in a group.

The use of PDN, respectively of IND resulted in a considerable decreasing of the neutrophils percentage in peripheral blood, statistically significant compared to saline group, in each moment of determinations, in carrageenan-induced paw inflammation model in rats. Intraperitoneal injection of the tested antibiotics was associated by a slight diminution in the percent of the serum neutrophils, statistically non-significant compared to the group treated with saline solution, during the experiment (fig. 2). Due to the absence of acute paw inflammation, control group has not been used in the blood tests.

No significant changes in the values of the ESR, between GEN, SMT groups and SS group were shown, during the experiment. The use of PDN, IND and CEF was associated by a decrease in ESR, statistically significant comparing with SS group at 24 hours and 72 hours (fig. 3).

The treatment with PDN, IND, CEF, GEN and SMT was associated with a significant decrease in plasma fibrinogen values, statistically significant comparing with control. The use of PDN, IND and SMT showed the strongest effects after 3 hours; of CEF at 3 hours and 72 hours; and of GEN after 72 hours in carrageenan-induced paw inflammation test in rats (fig. 4).

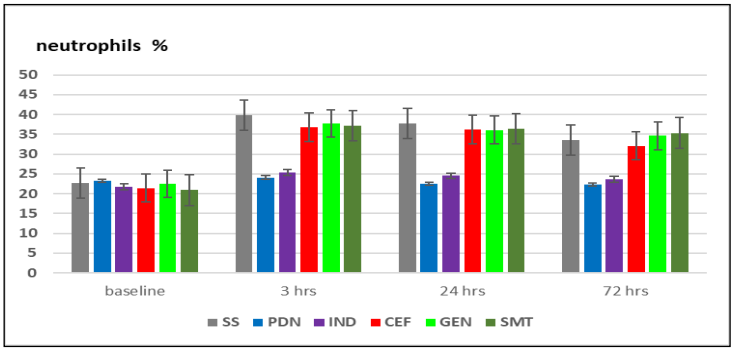

Fig. 2. The effects of CEF, GEN and SMT on the neutrophil's percentage in carrageenan-induced paw inflammation in rats.
Each point represents the mean ± S.D. of mean for 6 animals in a group.

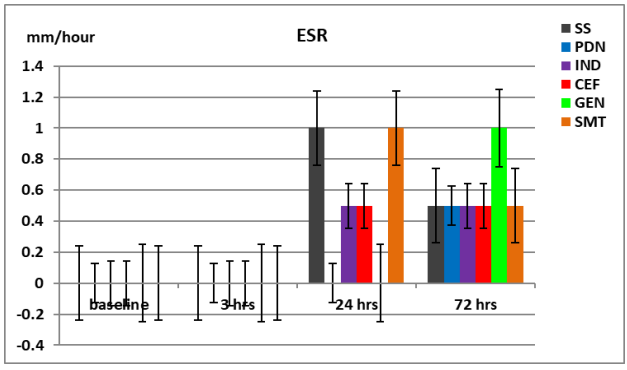

Fig. 3. The effects of CEF, GEN, SMT on the ESR (mm/hour) in carrageenan-induced paw inflammation model in rats.
Data are expressed as mean values ± S.D. of mean for 6 animals in a group.

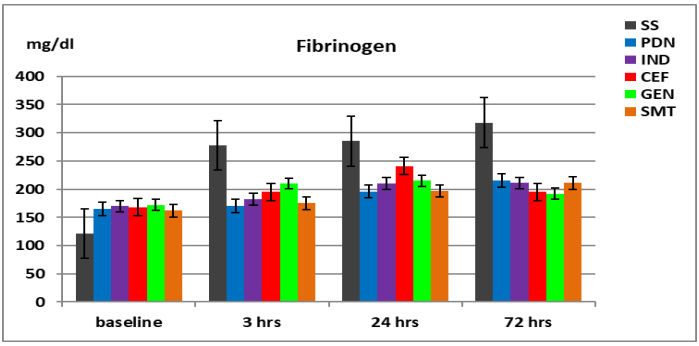

Fig. 4. The effects of CEF, GEN, SMT on the serum fibrinogen levels (mg/dL). Data are expressed as mean values ± S.D. of mean for 6 animals in a group.

DISCUSSION

Inflammatory reaction is of particular interest in immuno-pharmacology, the evaluation of the influence on the inflammatory response, being a key step in the testing of pharmacological agents. The inflammatory process is a complex of biochemical and cellular phenomena, evolving in cascade, that are activated in response to tissue damage or to the presence of foreign substances in the body. The observed effects of these two anti-inflammatory drugs PDN and IND, reinforce the idea of white blood cells involvement in the immune defense (17). Literature data (18) suggests that, the inflammatory process, can significantly influence the effects of chemotherapeutic drugs. Also, the various types of antibiotics interact with the cellular and/or humoral components of the immune system.

In terms of effects on the immune system, antibacterial substances have been classified into four groups: chemotherapeutic agents that do not alter the immune system: β-lactam antibiotics (with the exception of 3rd, 4th and 5th generation cephalosporin); aminoglycosides (depending on the dose); chemotherapeutic agents depressing the immune system: tetracyclines, rifampin, erythromycin, sulfonamides; chemotherapeutic drugs, that act synergistically with the immune system: macrolides, roxithromycin, quinolones; chemotherapeutic agents, that stimulate immune system functions: isoniazid, 3rd, 4th and 5th generation cephalosporin, aminoglycosides (depending on the dose) (19). Usually, the immune-compromised hosts (for example, in the case of human immunodeficiency virus infections) have difficulty in healing after the antibacterial treatment of opportunistic infections. Furthermore, acute or chronic infections or inflammatory processes, in these patients are resistant to many antimicrobial therapy schemas (20, 21).

In our experimental conditions, the local injection of carrageenan caused a visible inflammation, after about one hour with important edema, which increased the volume of the paw. Acute inflammation of the paw has progressively evolved, with a maximum intensity at 6 hours, which then has gradually diminished and maintained up to about 72 hours, after local administration of the irritant chemical agent.

The treatment with PDN and IND was associated with a reduction in the volume of the inflamed paw, statistically significant compared to the group receiving SS;

the anti-inflammatory effects of PDN being more intense than those of IND at any time of determination in the experiment. All three investigated antibacterial agents: CEF, GEN and SMT produced significant anti-inflammatory effects by reducing the volume of swelling that persist throughout the experiment. The most pronounced decrease in paw inflammation was produced by CEF, its effects being however lower than those of PDN and IND. The anti-inflammatory effects of the tested are positive correlated with the modifications of the white blood elements, which are specific for the assessing of the inflammatory process evolution.

The treatment with PDN, IND, CEF, GEN and SMT was associated with a significant reduction in plasma fibrinogen levels, statistically significant comparing with control group, in this experimental model of acute paw inflammation. The serum fibrinogen profile is directly linked with the changes in neutrophils percent values, during the progress of the inflammatory reaction.

CONCLUSIONS

We can appreciate that, in our experimental conditions, CEF manifested the most potent anti-inflammatory activity, compared to GEN and SMT at 3 hours and 6 hours, in this acute of paw`s inflammation test. The anti-inflammatory effects of CEF were less pronounced than those of PDN and IND, at each time point of the investigations, in the acute inflammatory edema test induced with carrageenan.

PRENYLATED COMPOUNDS FROM LEGUMES INDUCE ANTIBACTERIAL AND MEMBRANE PERMEABILIZATION OF *LISTERIA MONOCYTOGENES* AND *ESCHERICHIA COLI*

Background: Under (a)biotic stress, plants from Fabaceae family, produce prenylated phenolic compounds as a defense mechanism, which have shown very good antibacterial activity. Aim of the study: To study the antibacterial proprieties and the effects on the permeability of the bacterial membrane. Materials and methods: *L. angustifolius*, *A. hypogaea* and *G. max* underwent germination, CC extraction, RP-UHPLC-UV-MS analysis, antibacterial susceptibility and cell membrane permeability tests using fluorescent propidium iodine. Results: Pools contained cca. 165-350 mg prenylated phenolics/g. Chain prenylated isoflavones (*L. angustifolius*) were the most active against *L. monocytogenes* (10 μ/ml) compared to controls. None of the pools showed activity against *E. coli* alone. However, cIsf realized the most efficient permeabilization in combination with efflux pump inhibitor (EPI) PaβN, in a dose-dependent manner. Conclusion: Co-administration of prenylated isoflavones with EPI in-creased bacterial membrane permeabilization and an antimicrobial effect has been shown. Further experiments with different phenolic classes are necessary to confirm the antibacterial activity (Carla Araya-Cloutier, Jean-Paul Vincken, Roan van Ederen *et al*. Rapid membrane permeabilization of *Listeria monocytogenes* and *Escherichia coli* induced by antibacterial prenylated phenolic compounds from legumes *Food Chemistry* 2018; 240: 147-155).

THE ASSESSMENT OF RELATIONS BETWEEN MAIN HISTOLOGIC TYPE OF OVARIAN CANCER AND SOME RISK AND PROGNOSTIC FACTORS. (Abstract) : The authors have highlighted some aspects regarding the domestic risk and prognostic factors for different types of ovarian cancer. **Material and method** : The study has included 249 women diagnosed with ovarian cancer. **Results** : The assessment of age group distribution of patients with serous carcinoma (150 cases) underlying that the age group of 60-69 years was more frequent compared with the other age groups (OR = 0.20 ; IC 95% = 0.12–0.33 ; $p < 0.01 \times 10^{-5}$) and the mean of age was 61 years, 8 months, 19 days (DS = 11 years, 11 months, 22 days). The most frequent risk factor for serous type was the ovulation lifetime over 30 years (78.66%) ; followed by early menarche (under 12 years) (13.33%) ; smoking (12%) ; late menopause (over 52 years) (10%) and hormone replacement therapy (HRT) (2.67%), compared with mucinous carcinoma for which the most frequent was the ovulation lifetime over 30 years (65.21%) ; followed by early menarche (under 12 years) (34.78%) ; late menopause (over 52 years) (26.08%) and smoking (17.39%). **Conclusions** : The ovulation lifetime over 30 years was identified as the main risk factor for both histological types, but it was significant more frequent among women with serous type. The smoking was more frequent among those who had mucinous carcinoma compared with serous type. No significant differences were identified among women with both histological types regarding the age at first menstrual bleeding and parity. **Key words** : OVARIAN CANCER, RISK FACTORS, PROGNOSTIC FACTORS, HISTOLOGICAL TYPE

The ovarian cancer comprises a family of malignant entities presenting a great histo-pathological and biological diversity (1,2). All these histo-pathological types differ by the cell line from which they grow, frequency, risk factors, the rate of progression, the possibility of early detection, prognosis and response to treatment (4,5,6,7,8,9,10,11,12).

The epithelial cancers account for 90% of ovarian cancers, and, among these, the most common histological types are serous (75-80%), mucinous (10-15%), endometrioid (9-25%) and with clear cells (5-13%). The uncommon types are *Brenner tumors*, those with *small cells* and the *undifferentiated* cancers (3,4,5,11).

In many epidemiological studies and clinical investigations on confirmed and well

established risk factors, such as the nuliparity or not using oral contraceptives (OC), ovarian malignancies have been treated as a single condition, without distinguishing between histological types. The first reporting of differences in risk factors for epithelial ovarian cancer according to histological type was that of Rich et al., 1996 (13) identifying a protective role of reproductive factors, such as parity (multiple births) and the use of O.C., regarding non-mucinous tumors, but not to the serous tumors.

The diverse potential impact of ovarian cancer risk factors on different histological types of disease has not been well investigated, some studies suggesting that the mucinous ovarian neoplasia differs in several respects from other types, that involving a different approach of these malignancies in the aspects of carcinogenesis, diagnosis, prevention, treatment and prognosis (7,8,9,10,12,14, 15,16,17).

In these circumstances we considered appropriate to realize a survey on the influence of risk factors on different histological types of ovarian cancer.

The purpose of this study was to evaluate the relationship between the main histological types of ovarian cancer and some risk or prognostic factors in the studied population.

Study objectives were: to highlight the characteristics of sublots with serous and mucinous histologic type; to characterize of risk factors for the two most common histological subtypes identified in the studied population; to analyze relationships between identified factors and histological subtypes of interest.

MATERIAL AND METHODS

The study included 249 patients diagnosed with ovarian cancer. The patients with ovarian cancer selected from the Outpatient Oncology Department (Oncology County Office) and the Department of Oncology from the University Hospital St. Spiridon Iaşi, in 1999-2009, were divided in two subgroups according to their appurtenance to a particular histopathological type, which were compared then in terms of risk factors. Epidemiological data were collected via a questionnaire validated in a previous study (18), they were included in a database in Excel, which was then processed using the program *Epi Info 3.5.1*. In interpretation the results, values of $p < 0.05$ were considered significant.

RESULTS

The distribution of cases after histological types reveals the predominance of serous carcinomas. Most of them (70%) were serous and mucinous carcinomas (60.24%, and 9.24%, respectively), 6.02% were un-

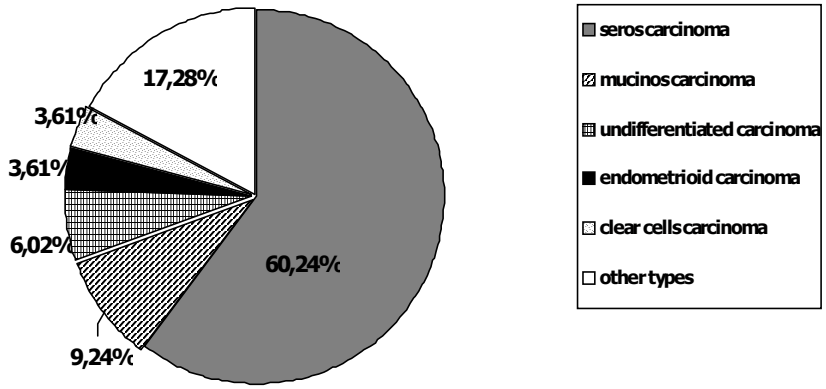

Fig. 1. The distribution on histological types of the patients with ovarian cancer

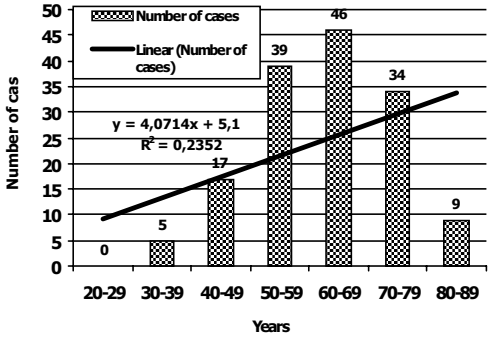

Fig. 2. The groups distribution trend of diagnosed patients with serous ovarian carcinoma

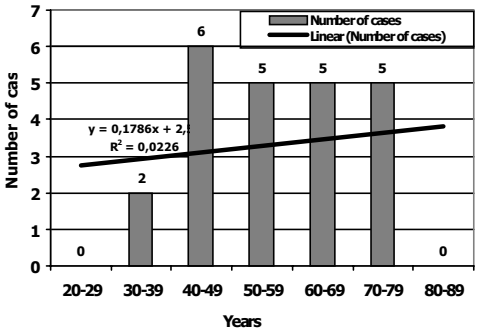

Fig. 3. Age distribution of cases diagnosed with ovarian mucinous carcinoma

differentiated carcinomas, endometrioid and clear cell carcinomas were 3.61% each, and the rest were histological types, in small proportions (Krukenberg tumor, squamous carcinoma, small cells carcinoma, disgerminom, granulosa carcinoma, teratoma, sarcoma, endodermal sinus carcinoma)(Fig. 1).

The evaluation of age-group distribution of patients with serous carcinoma (150 cases) shows the prevalence of the age group 60--69 years, compared with the other age groups ($p < 0.01$ x10-5) (Fig. 2) with an average age of 61 years (SD = 12 years). The average age at the time of diagnosis was slightly higher compared with women hospitalized for mucinous ovarian carcinoma (serous - 56 years versus mucinous - 51 years).

In Table I there is collated information on risk factors for serous type of ovarian cancer. We can notice that between risk factors for this histologic type, the most common was ovulatory period more than 30 years (78.66%), followed by early menarche (under 12 years) (13.33%), smoking (12%), late menopause (over 52) (10%) and hormone replacement therapy (HRT) (2.67%).

For patients with mucinous ovarian carcinoma (23 cases), the most affected age group was 40-49 years (as the scientific literature specificates) ($p = 0.003$) (Fig. 3), with an average age of 57 years (SD = 13 years).

In Table II there is collated information on risk factors for mucinous type of ovarian cancer. It notes that between risk factors for this histologic type, the most common was the ovulatory period more than 30 years (65.21%); followed by early menarche (under 12 years old) (34.78%); late menopause (more than 52 years old) (26.08%)

TABLE I

The relation of studied factors with the risk of serous ovarian cancer in the analysed population studied

No.	Studied factor	Number of patients	Frequency (%)	OR	IC	p
1.	Ovulatory period > 30 years	118	78.66	13.6	7.56 – 24.62	$<0.01 \times 10^{-5}$
2.	Early menarha (under 12 years)	20	13.33	0.02	0.01 - 0.05	$<0.01 \times 10^{-5}$
3.	Smoking	18	12	0.02	0.01 – 0.04	$<0.01 \times 10^{-5}$
4.	Late menopause (over 52 years)	15	10	0.01	0.01 – 0.03	$<0.01 \times 10^{-5}$
5.	THS	4	2.67	0.00	0.00 – 0.00	$<0.01 \times 10^{-5}$

* for values < 5, we applied the Yeats correction

TABLE II
The relations of studied factors with the risk for mucinous ovarian cancer in the studied population

No.	Studied factor	No. of patients	Frequency (%)	OR	IC	*p*
1.	Ovulatory period > 30 years	15	65.21	3.52	0.89 – 14.83	0.076
2.	Early menarha (under 12 years)	8	34.78	0.20	0.07 - 1.12	0.070
3.	Late menopause (over 52 years)	6	26.08	0.12	0.03 – 0.55	0.003
4.	Smoking	4	17.39	0.04	0.01 – 0.25	$<0.01x10^{-5}$

* for values < 5, we applied the Yeats correction

and smoking (17.39%).

Regarding the comparison between serous and mucinous carcinoma, applying t-Student significance test, we noticed the following (Table III) :

- the average age of patients with serous carcinoma is significantly higher than the average age of patients with mucinous carcinoma (p = 0.035) ;
- the average age for diagnosis of serous carcinoma is significantly higher compared with the average age for diagnosis of mucinous carcinoma (p = 0.021) ;
- the average age of installing of menopause in patients with serous carcinoma is significantly higher than the average age of patients with mucinous carcinoma (p = 0.025) ;
- the average duration of exposure to estrogen (ovulatory period) in patients with serous carcinoma is significantly higher than the average duration of exposure to estrogen of patients with mucinous carcinoma (p = 0.038).
- on the number of births and age at first menstruation, the differences between patients in the 2 subgroups were insignificant.

TABLE III
Characteristics of studied factors that have statistic significance in serous carcinoma compared with the mucinous

No.	Risk factor	*t-Student Test*	*p*
1.	Ovulatory period > 30 years	2.08	0.021
2.	The average age at time of diagnosis	2.32	0.025
3.	The average age at menopause	2.25	0.038

If analysing the serous carcinoma compared with mucinous, applying the significance test χ^2 we have found the following results :

- patients whose menarche occurred before 12 years are more common among those with mucinous compared to serous carcinoma (p = 0.009) ;
- patients whose menopause installed after the age of 52 years are more common among those with mucinous compared to serous carcinoma (p =0.028) ;
- patients who smoked had a higher frequency among those with mucinous carcinoma compared with the serous (p = 0.046) ;
- in terms of personal history (polycystic ovary, endometriosis, infertility) we ob-

TABLE IV
Characteristics of studied factors that have statistic significance for serous carcinoma compared with the mucinous

No.	Risk factor	χ^2	*p*
1.	Ovulatory period > 30 years	6.72	0.009
2.	The average age at time of diagnosis	4.81	0.028
3.	The average age at menopause	3.96	0.046

served no statistically significant differences between the two histologic types (Table IV).

DISCUSSIONS

Histopathologic distribution observed in this study is consistent with published data (8,9,15). With regard to potential sources of error, the selection should not have a big influence on the results, because cases and controls were selected from hospitals covering the same region, the participation in the study was almost complete, and women with chronic, gynecological or hormonal diseases have been excluded.

In an Italian study (9) parity was inversely associated with risk for non-mucinous cancers, but not for mucinous ones. Other studies show that pregnancy is associated with reduced risk for all histological types of cancer. In the current study, for a number of 249 cases, the pregnancy was not significantly associated with reduced risk for ovarian cancer for either of the two major histological types identified in the population studied.

A protective role of O.C. use in serous and endometrioid tumors, but not for mucinous ones was reported by Modugno (19). Risch et al. (13) have also identified a stronger protection of O.C. in non-mucinous cancers (OR = 0.89) compared with mucinous (OR = 0.98).

Hormone replacement therapy (HRT) (non-contraceptive estrogens) increases the risk of endometrioid ovarian cancer but not for other types (13). Chiaffarino et al (9) found no difference between the different histological types.

In their study, Kurian et al. (8) found a positive association of *serous ovarian carcinoma* and a family history of breast, ovarian or colorectal cancer (OR = 2.9, CI = 2.2 to 3.7) and an inverse association with body mass index (BMI) (OR = 0.72, CI = 0.59 to 0.88), educational level (OR = 0.76, CI = 0.64 to 0.90) and tubal ligation (OR = 0.68 , CI = 0.50 to 0.95). The authors also showed that histological type is not associated with smoking (OR = 1, CI = 0.77 to 1.3). We have identified also similar results in our current research, in terms of BMI and educational level. As for *mucinous carcinoma*, this was the only one positively associated with smoking (OR = 2.4, CI = 1.5 to 3.8). Another significant positive association is with family history of breast, ovarian or colorectal cancer (OR = 1.8, CI = 1.1 to 3.2) and insignificant with BMI (OR = 1.3, CI = 0.88 - 2.00). Cited research found an inverse association of mucinous histologic type with the educational level (OR = 0.69, CI = 0.49-0.98) and no association with tubal ligation (OR = 0.89, CI = 0.49 -1.6) (8), a situation also found in the current study.

In contrast to the results from Kurian et al. (8), who found, in their research, no association with age at first menstruation, age at menopause, number of incomplete pregnancies (abortions), duration of HRT use or alcohol consumption, this study has identified early menarche, late menopause and smoking as risk factors for mucinous ovarian cancer. For all histological types we observe a descending trend with increasing parity : serous (OR = 0.87, CI = 0.83 to 0.91), mucinous (OR = 0.85, CI = 0.77 to 0.93), endometrioid (OR = 0.72, CI = 0.66 to 0.77) and with clear cell (OR = 0.56, CI = 0.49-0.65). A number of 3-4 births protects against ovarian cancer risk, endometrioid histologic and with clear cells type (8).

All histological types of ovarian cancer, except that with clear cells, showed an inverse association with lactation : serous (OR = 0.98, CI = 0.97-0.99), mucinous (OR = 0.97, CI = 0.95 to 1), endometrioid (OR = 0.98, CI = 0.96 to 1) and with clear cells (OR = 1, CI = 0.97 to 1.03). An inverse association with CO was observed for all histological types : serous (OR = 0.66, CI

= 0.55 to 0.80), mucinous (OR = 0.60, CI = 0.43 to 0, 84), endometrioid (OR = 0.70, CI = 0.52 to 0.93) and with clear cells (OR = 0.65, CI = 0.41 to 1) (8).

Another study investigating risk factors and histological types of ovarian cancers is that of Tung et al (15). The authors state that : women with mucinous type of ovarian cancer had a lower education level compared with those who have non-mucinous types ; those in postmenopausa had a risk of developing malignant ovarian tumors 2 times higher than those in premenopausal, the association being stronger in those with non-mucinous invasive cancer (particularly serous and endometrioid). Our results were in contrast with the findings of Tung team.

In terms of total number of years the woman has menstrual cycle, it was correlated with an increase of the risk for non-mucinous tumors, but not for mucinous ones (p = 0.001) (15), data which this research were consistent. We noticed a significant positive association with risk for non-mucinous carcinomas, but not for mucinous ones, with increasing number of lifetime ovulatory cycles (p = 0.005).

Pregnancy was associated with reduced risk for all histological types - women who had at least one pregnancy had a significantly lower risk for invasive endometrioid cancer or with clear cell than those without any birth ; except for mucinous cancers, breast--feeding by suppressing ovulation, also reduces the risk for non-mucinous types, especially endometrioid and with clear cells (p = 0.03), consumption of CO was associated with decreased risk for all types (15). For these factors, our study has not identified differences between histological types.

In the Tung et al study (15), ovulation factors (age at menopause and at first menstruation) had little influence on the risk for all histological types. Neither in our study we showed no strong relationship between these factors and the risk for ovarian cancer.

CONCLUSIONS

1. The average age of patients, the mean age at diagnosis clarification, and the average age of menopause instauration in patients with serous carcinoma is significantly higher than that of subjects with mucinous carcinoma.
2. The ovulatory period (median duration of exposure to endogenous estrogens) in patients with serous carcinoma is significantly higher than during the ovulatory period at patients with mucinous carcinoma.
3. There are no significant differences between patients with both histological types in terms of age at first menstruation and parity.
4. Patients who had their first menstruation before the age of 12 are more common among those with mucinous carcinoma, compared to serous carcinoma ; those with menopause installed after the age of 52 years are more common among those with mucinous carcinoma compared with the serous.
5. Patients who smoked were more common among those with mucinous carcinoma, compared to serous carcinoma, and in terms of personal history (uterine polyps, polycystic ovary, infertility) there are no statistically significant differences between the two histological types.
6. Ovulatory period of more than 30 years was identified as the main risk factor for both histological types.

ACKNOWLEDGEMENTS

This study was performed under CNCSIS ID_2500/2008 code, contract no. 1129/2009 - funded by the Executive Unit for Higher Education and Educational Research Financing (UEFISCSU) in the Exploratory Research Projects, “IDEAS” Programme of the National Council of Scientific Research in Higher Education.

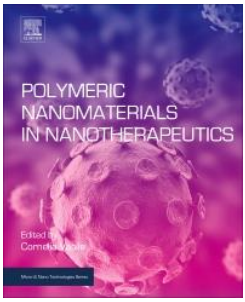
BOOK REVIEW



POLYMERIC NANOMATERIALS FOR NANOTHERAPEUTICS

Ed. C. Vasile, Elsevier, 1st Edition. 2018. Series Volume Editor: Cornelia Vasile,
eBook ISBN: 9780128139332; Paperback ISBN: 9780128139325:
Elsevier, Published Date: 2nd November 2008; 558 pages In Micro and Nano Technologies Series.

Polymeric Nanomaterials in Nanotherapeutics describes how polymeric nanomaterials are used in the obtainment of nanosensors and nanorobotics as biomedical instrumentation, surgery, diagnosis and controlled and targeted drug delivery for cancer, improved pharmacokinetics, monitoring of diabetes and other healthcare problems. Polymeric nanomaterials (synthetic and/or natural) used for these purposes described in this book are: polymers as drugs, polymer drug conjugates, polymeric nanoparticles, micelles, nanogels, nano emulsions, viruses, dendrimers, polyplexes, multi-functional nanoparticles, polymersomes, viral nanoparticles, stimuli-responsive nanomaterials, etc. Various ways of drug administration and to create drug formulations for controlled and targeted delivery and release of active agents (drug molecules) to non-healthy tissues and cells as new nanotherapeutics are described. As methods of administration described are included oral, dental, topical and transdermal, pulmonary and nasal, ocular, vaginal, and brain drug delivery. In different chapters it is demonstrated how these nanotherapies are applied to dental work, wound healing, cancer, cardiovascular diseases, neurodegenerative disorders, infectious diseases, chronic inflammatory diseases, metabolic diseases, and more.

In most cases are presented new drugs existing in various stages of development as: FDA or EU-approved polymeric or polymers containing "nanopharmaceuticals", commercial state as *Abraxane case* or in different clinical trials or in research stage. The applications are depended on physicochemical properties of nanomaterials, and because of the novelty of both drugs and carrier systems the risk assessment is necessary to be established. Therefore, the toxicity and regulatory status of therapeutic polymeric nanomaterials are also examined. All the 15 chapters are written by experts in the field.

As key features of the book it can be mentioned: it is demonstrated how the properties of polymeric nanomaterials can be used to create more efficient medical treatments/therapies; the potential and range of applications of polymeric nanomaterials in disease prevention, diagnosis, drug development, and for improving treatment outcomes, it is explained in detail how nanotherapeutics can help in solving problems in the field through the latest technologies and formulations.

The book gives a broad perspective on the topic for researchers, postgraduate students and professionals in the fields of nanomaterials, biomaterials, biotechnology and applications in biomedical fields and medicine.

PSA AS A MARKER FOR PROSTATE CANCER PROGRESSION (Abstract): Monitoring the evolution of prostate cancer has crucial importance since this tip of neoplasia has a variable biology, ranging from latent cancers to extremely aggressive tumors. At the moment, PSA (prostate specific antigen) values point out to either successful or unsuccessful prostate cancer therapy. Depending on therapeutic strategies, biochemical recurrence (BCR) is differently defined. After radical prostatectomy, the PSA declines to undetectable levels in 3-4 weeks; BCR: PSA = 0.2-0.5 ng/mL for a single measurement or two consecutive values which surpass 0,2-0,4 ng/mL. PSADT < 10 months is a predictor for the progression of the disease. After external beam therapy, PSA is slowly decreasing reaching up the nadir of 0.2-0.5 ng/mL in months or years; BCR: PSA = nadir + 2 ng/mL. In the case of brachytherapy, the nadir is reached in 2-4 years; BCR: nadir + 2 ng/mL. After hormonal therapy, PSA declines in 3-6 months, maintains low values for 18-24 months, then increases, settling for hormone independency. After chemotherapy, PSA is considered normal at values < 2 ng/mL; the response of PSA represents a confirmed decreasing from the second test at 4 or more weeks after the initial decline; the length of the response is the period between first decline with 50 % of PSA to 50 % increase from nadir; the progression of PSA is shown in the increase with 25 % in comparison to the basic level. In the case of active monitoring, a PSADT < 2 years is an indication for radical prostatectomy, but there are cancers which can evoluate despite a stable PSA. The „PSA bounce" phenomenon and the „PSA surge postchimiotherapie" syndrome can complicate the assessment of biochemical recurrence. **Key words**: PSA, PROGRESSION OF PROSTATE CANCER, BIOCHEMICAL RECURRENCE/ RECURRENCE OF TUMORAL MARKERS

Cancerul de prostată se remarcă prin eterogenitate la nivel clinic, histologic şi biologic. În prostată pot coexista în acelaşi timp celulele epiteliale canceroase în diferite pattern-uri arhitecturale şi diferite grade de diferenţiere (care se reflectă în scorul Gleason), celule stromale fibromusculare, multipli foci de neoplazie intraepitelială benignă (PIN), leziuni atrofice, noduli de hiperplazie prostatică benignă (BPH) şi glande normale. Clasic, se consideră că multe cancere umane se dezvoltă printr-o serie de etape genetice secvenţiale care culminează în carcinom şi boala metastatică, iar acestea se reflectă la nivel genetic, histologic şi clinic. Multe aspecte din biologia cancerului de prostată nu se potrivesc acestui model. Tehnicile genetice clasice au adus informaţii limitate cu privire la procesul progresiei cancerului de prostată (1).

Cel mai utilizat marker, în prezent, pentru urmărirea evoluţiei cancerului de prostată este PSA (antigenul specific prostatic). PSA este eliberat în sistemul circulator când

membrana bazală prostatică este compromisă, cum se întâmplă în cancer, şi, prin urmare, este utilizat ca marker seric sensibil pentru screening-ul, diagnosticul şi progresia cancerului de prostată. (În lucrarea noastră nu ne vom referi la rolul determinant al PSA în screening-ul şi diagnosticul neoplaziei prostatice, ci doar la rolul său în urmărirea evoluţiei cancerului, în cursul sau după diferite terapii). De fapt detecţia recidivei bolii a fost aplicaţia clinică iniţială a PSA în cancerul de prostată (2).

PSA, o serinprotează produsă de celulele epiteliale secretorii, este codificat de gena kalicreinei umane 3 (hK3). Expresia PSA este AR (receptor androgenic) - dependentă, iar nivelele transcripţionale sunt semnificativ reduse în absenţa androgenilor (3). Alături de PSA total, în urmărirea evoluţiei cancerului de prostată s-au remarcat a fi utile derivatele acestuia, în principal PSADT (timpul de dublare al PSA) şi PSAV (velocitatea PSA).

Aproximativ o treime până la jumătate din pacienţii trataţi, indiferent de metoda terapeutică, vor experimenta recidivă biochimică (creşterea valorilor PSA după normalizarea lor iniţială)(4). Semnificaţia recidivei biologice este, ea însăşi, neclară, întrucât nu toţi pacienţii cu recidivă biochimică vor experimenta boala metastatică. Se defineşte astfel recurenţa biochimică agresivă, pentru valori ale PSADT < 6 luni (5).

Recurenţa biochimică reprezintă un marker al progresiei spre boala metastatică şi al mortalităţii cancer-specifică (6). Momentul recurenţei biochimice postterapie este crucial în urmărirea evoluţiei cancerului prostatic, deoarece permite administrarea precoce a terapiei de salvaj în cazul pacienţilor cu recurenţă locală.

RECURENŢA BIOCHIMICĂ DUPĂ PROSTATECTOMIA RADICALĂ

Nivelul seric al PSA ar trebui să scadă la valori nedetectabile ($< 0,1$ ng/mL) în 3-4 săptămâni după prostatectomia radicală. Definiţia recurenţei biochimice variază de la valori cuprinse între 0,2 ng/mL şi 0,5 ng/mL, pentru o singură măsurătoare, la două valori consecutive care depăşesc 0,2 sau 0,4 ng/mL. Un nivel al PSA $\geq 0,4$ ng/mL este asociat puternic cu progresia bolii şi este considerat că defineşte recurenţa biochimică, care poate avea loc după mai mulţi ani de la prostatectomia radicală (7). 27% din recidivele biochimice apar la mai mult de 5 ani de la prostatectomie radicală, iar riscul de recurenţă continuă până la 15 ani postoperator, ceea ce impune urmărirea prelungită a valorilor PSA (6).

În prezent pacienţii sunt monitorizaţi, în ce priveşte valoarea PSA, o dată la 3 luni în primul an, la 6 luni pentru următorii 4 ani, şi apoi anual. Intervalul de timp dintre recurenţa biochimică şi metastaze depinde de stadiul patologic preoperator, de scorul Gleason şi de PSADT postoperator. Un PSADT mic (< 10 luni) este cel mai puternic predictor pentru progresia bolii. În cazuri rare, pacienţii pot dezvolta metastaze la distanţă postprostatectomie fără creşterea nivelului PSA.

Pound et al. au raportat o recurenţă biochimică în 15 % din cazuri şi metastaze osoase în 5 % din cele 1997 cazuri de pacienţi cu stadiu clinic T1-2 trataţi prin prostatectomie radicală, după o monitorizare de 5 ani (8). Timpul median de la recurenţa PSA la metastaze a fost de 8 ani. După dezvoltarea metastazelor, timpul median până la deces a fost de 5 ani. Factorii de risc pentru progresia către metastazele osoase, după prostatectomia radicală, au inclus un scor Gleason ≥ 7, prezenţa invaziei veziculelor seminale, sau atingerea ganglionară, sau recurenţa biochimică < 2 ani de la prostatectomie.

Recurenţa biochimică agresivă poate fi, din fericire, identificată precoce în cursul bolii pe baza PSADT scurt postoperator (< 6 luni). Timpul până la recurenţa bio-

chimică se corelează cu supravieţuirea cancer specifică, dar el nu este un indicator pentru moartea prin cancer. Dimpotrivă, un PSADT foarte scurt este un indicator pentru moartea prin cancer (5). Pacienţii cu PSADT < 3 luni prezintă un risc extrem de crescut pentru rezultate clinice negative. Dimpotrivă, bărbaţii cu PSADT > 15 luni au un risc foarte mic pentru moarte cancer-specifică (9).

Conform unui studiu canadian, numai 30% din pacienţii cu recurenţă biochimică după prostatectomia radicală au prezentat metastaze la distanţă, iar 20% au murit de cancer de prostată la 15 ani după recurenţa biochimică. 40% dintre pacienţii cu metastaze osoase mor de cancer la 5 ani după apariţia lor. Mortalitatea prin cancer la 5 ani după diagnosticarea metastazelor este de 40% (8).

RECURENŢA BIOCHIMICĂ DUPĂ RADIOTERAPIA EXTERNĂ

Nivelul PSA descreşte lent şi e posibil să nu atingă niciodată nivele nedetectabile după radioterapia externă. Uneori se atinge nadirul (0,2-0,5 ng/mL) (4) după luni sau chiar ani, în funcţie de doza de iradiere, mărimea prostatei şi valoarea PSA pretratament. Recurenţa biochimică după radioterapia definitivă a fost iniţial definită de către American Society for Therapeutic Radiology and Oncology (ASTRO) drept trei creşteri consecutive ale PSA după ce se atinge nadirul (10). Ulterior, conform definiţiei Phoenix (7), recurenţa biochimică a fost definită drept creşterea absolută cu ≥ 2 ng/mL faţă de nadir (creştere continuă, fără reducere). Totuşi, ca şi în cazul prostatectomiei radicale, eşecul clinic postiradiere poate fi apreciat mai bine de către PSADT decît de valorile absolute ale PSA. Ca şi în cazul pacienţilor trataţi chirurgical, bărbaţii cu PSADT < 3 luni (calculat după substracţia nadirului PSA) prezintă un risc extrem de crescut, cu mortalitate cancer-specifică atingând 100% (9).

Există un fenomen – *saltul PSA (PSA bounce)* – observat la 10-30% dintre pacienţii trataţi prin radioterapie externă, care apare de obicei în primele 9 luni postterapie, dar care poate să apară până la 60 de luni după tratament. Este o creştere tranzitorie a PSA de cel puţin 0,4 ng/mL sau o creştere de 15% faţă de PSA precedent, care ulterior dispare spontan. Etiologia fenomenului nu este cunoscută. Pentru a distinge între recurenţa biochimică şi *"saltul PSA" (PSA bounce),* se consideră că are loc recurenţa biochimică dacă se înregistrează valori nadir plus 2 ng/mL (4).

RECURENŢA BIOCHIMICĂ DUPĂ BRAHITERAPIE

După brahiterapie, regresia valorilor PSA este lentă, atingându-se nadirul la 2-4 ani (11). Supravieţuirea fără recurenţă biochimică la 5 şi 10 ani a fost raportată ca fiind 71-93%, respectiv (65-85%) (12).

"Saltul PSA" este frecvent după brahiterapie (32-46 %). În unele studii, pacienţii care au experimentat "saltul PSA" au prezentat o probabilitatea mai redusă pentru recurenţa biochimică (4).

Prognosticul pentru pacienţii trataţi prin brahiterapie şi care nu prezintă recurenţă biochimică la 5 ani este excelent. Este improbabil ca pacienţii cu valori < 0,2 ng/mL la 5 ani posttratament să prezinte o recurenţă biochimică ulterioară (13).

Standardul "nadir + 2", valabil pentru recurenţa biochimică postradioterapie externă, este valabil şi pentru pacienţii trataţi prin implant radioizotopic (2).

PSA ÎN MONITORIZAREA ACTIVĂ ŞI *WATCHFUL WAITING*

Monitorizarea activă este o alternativă terapeutică pentru pacienţii cu cancer de prostată cu risc mic de progresie. Bărbaţii cu cancer de prostată bine diferenţiat au o supravieţuire la 20 de ani de 80-90%. Moni-

torizarea activă implică urmărirea regulată a evoluţiei bolii (prin PSA, DRE şi, posibil, repetarea periodică a biopsiei) în vederea instituirii terapiei curative, când există indicii că boala progresează (14).

Monitorizarea activă este indicată în cazul cancerelor localizate (T1c-T2), de grad mic (< 3) şi de volum < 0,5 cm^3, cu valori ale PSA < 10 ng/mL, cu scorul Gleason = 6 (12). Acestea sunt cancerele considerate, conform nomogramelor, cu potenţial evolutiv redus. Dozajul PSA se realizează la fiecare 6 luni timp de 4 ani, apoi anual (15). PSADT este un indicator important în strategia de monitorizare a acestor cancere, pentru a indica necesitatea unui tratament. Se consideră că un PSADT < 2 ani constituie indicaţie terapeutică de prostatectomie totală, dar există cancere care pot progresa în ciuda unui PSA stabil (11). Un studiu recent al Universităţii *John Hopkins* susţine că cinetica PSA postdiagnostic nu reprezintă un test prognostic valid şi nu ar trebui utilizată pentru înlocuirea biopsiei anuale pentru urmărirea bărbaţilor prin monitorizare activă (16).

Spre deosebire de monitorizarea activă, *watchful waiting* implică o urmărire mai puţin agresivă şi, în general, absenţa tratamentului până la apariţia bolii simptomatice (14).

Această alternativă terapeutică este aplicată în cazul pacienţilor cu boală incurabilă. Terapia de privare androgenică, recomandată acestor pacienţi, este aplicată fie în cazul creşterii valorii absolute a PSA, fie când PSADT < 6 luni (4).

PSA ÎN CAZUL PACIENŢILOR TRATAŢI HORMONAL

După tratamentul hormonal, nadirul PSA este un factor prognostic important, care se corelează cu timpul de supravieţuire fără recidivă. Valoarea PSA descreşte în 3-6 luni şi se menţine la valori scăzute timp de 18-24 de luni, după care survine o creştere a PSA, care defineşte hormono-independenţa. Când PSA continuă să crească după a doua linie de hormonoterapie, este vorba de hormono-rezistenţă (11). Recidiva metastatică este asociată întotdeauna cu creşterea PSA, în afara cazurilor rare de tumori nediferenţiate, când PSA poate rămâne nedetectabil.

EVALUAREA RĂSPUNSULUI LA CHIMIOTERAPIE

Normalizarea PSA este considerată la valori < 2ng/mL. Un răspuns al PSA este demonstrat de descreşterea PSA confirmată de un al doilea test, la 4 sau mai multe săptămâni după declinul iniţial. Durata răspunsului PSA reprezintă perioada dintre prima reducere cu 50% a PSA până la 50% creştere de la nadir. PSA este considerat că progresează când creşte cu 25% faţă de nivelul de bază sau când există o creştere progresivă în valoare absolută a PSA de cel puţin 5ng/mL (17).

Thuret et al. au studiat modificările iniţiale ale PSA în cursul chimioterapiei la pacienţii cu cancer de prostată hormono-refractar şi au corelat aceste modificări cu răspunsul ulterior la terapie. S-a observat că PSA poate creşte iniţial (în 20% din cazuri), apoi descreşte, la pacienţii cu un răspuns bun la chimioterapie. Acest fenomen – numit sindromul *PSA surge post-chimioterapie* – a fost observat în primele 1-8 săptămâni după iniţierea chimioterapiei. Aceeaşi observaţie este valabilă pentru chimioterapia second line. Cunoscând acest fenomen, clinicienii vor evita întreruperea precoce, inoportună, a chimioterapiei (18).

TRATAMENTUL METASTAZELOR OSOASE

O constatare neaşteptată în studiul lui Porter et al. a fost o reducere semnificativă a valorilor PSA în grupul tratat cu ^{89}Sr. S-a sugerat astfel că tratamentul cu radiofarmaceutice cu tropism osos ar putea exercita, dincolo doar de ameliorarea durerii,

un efect tumoricid important (19).

DIFERENŢIEREA ÎNTRE RECIDIVA LOCALĂ ŞI RECIDIVA METASTATICĂ

După prostatectomia radicală sau radioterapie pentru un stadiu localizat, intervalul mai scurt de un an înaintea recidivei biologice, creşterea rapidă a valorilor PSA cu o velocitate crescută (în ng/mL pe an) sau un PSADT scurt sunt în favoarea unei recidive metastatice la distanţă, în timp ce o creştere lentă în mai mult de un an a PSA ar sugera mai curând o recidivă locală (11). Caracteristicile anatomopatologice şi biologice în favoarea unei recidive locale, după prostatectomia radicală, sunt scorul Gleason ≥ 7 (3+4), stadiul pT3, pN0, reascensiunea PSA după mai mult de un an şi un PSADT $>$ 10 luni. În favoarea unei recidive metastatice pledează un PSA detectabil în mai puţin de un an postoperator, un PSADT inferior la 4-6 luni, un scor Gleason = 7 (4+3) şi un stadiu pTxN1.

După radioterapie, valoarea nadirului PSA $<$ 2 ng/mL, timpul până la nadir de 12-18 luni şi un PSADT de 11-13 luni sunt în favoarea unei recidive locale. Un nadir al PSA $>$ 2 ng/mL, obţinut în mai puţin de 12 luni şi un PSADT de 3-6 luni pledează pentru o recidivă la distanţă (11).

PROGRESE ÎN URMĂRIREA EVOLUŢIEI CANCERULUI DE PROSTATĂ

Modificările moleculare care determină progresia cancerului de prostată de la glandele benigne, la leziunile precursoare, cancerul local şi în final boala metastatică sunt puţin înţelese. Tehnicile *ADN microarray* au permis studiul unor aspecte ale progresiei cancerului de prostată. În această progresie sunt implicate mai multe gene şi căi, precum *GSTP1*, *PTEN*, *NKX3.1*, *AR*, *c-MYC* şi calea de semnalizare *hedgehog* (1). Studiile s-au concentrat pe identificarea profilului expresiei genice caracteristic pentru diferite scoruri Gleason. *SPARC* a fost asociată cu un scor Gleason mare. Alte studii au avut drept scop identificarea genelor diferenţial exprimate în cancerul local comparativ cu cel metastatic. De exemplu într-un model Cox care a inclus statusul marginii chirurgicale, mărimea tumorii, scorul Gleason şi valoarea PSA preoperator, expresia crescută a proteinei EZH2 a fost cel mai bun predictor al recurenţei (1). Câteva studii s-au concentrat pe identificarea profilului care anticipează care dintre cancerele localizate sunt mai predispuse la recurenţa PSA după prostatectomie. Astfel pierderea genei *TRPM8* constituie un predictor semnificativ pentru recurenţa biochimică.

CONCLUZII

Detecţia recidivei cancerului de prostată a fost prima aplicaţie clinică a PSA. În prezent, PSA continuă să fie cel mai utilizat marker pentru urmărirea evoluţiei bolii. Recurenţa biochimică este diferit definită, în funcţie de diferitele strategii terapeutice :

1. După prostatectomia radicală, PSA descreşte la valori nedetectabile în 3-4 săptămâni. BCR : PSA = 0,2-0,5 ng/ pentru o singură măsurătoare sau două valori consecutive care depăşesc 0,2-0,4 ng/mL.
2. După radioterapia externă, nadirul de 0,2-0,5 ng/mL se atinge în luni sau ani. BCR : PSA = nadir + 2 ng/mL.
3. În cazul brahiterapiei, nadirul este atins în 2-4 ani. BCR : PSA = nadir + 2 ng/mL.
4. După terapia hormonală, PSA descreşte în 3-6 luni, se menţine la valori scăzute 18-24 de luni, după care creşte, instalându-se etapa de hormono-independenţă.
5. După chemoterapie, PSA este considerat normal la valori $<$ 2 ng/mL.
6. În cazul monitorizării active, un PSADT $<$ 2 ani constituie indicaţie pentru prostatectomia radicală.

Conform consensului ASTRO, este important de notat că definiţiile propuse preci-

zează succesul sau eşecul terapeutic în contextul unei populaţii, nu al unui individ (2). Ele oferă un context în care fiecare caz clinic va fi judecat individual.

ANATOMICAL VARIATIONS OF LANDMARKS IN ENDOSCOPIC SURGERY OF THE PARANASAL SINUSES REVEALED BY MRI IMAGING (Abstract): Continue development of endoscopic techniques of rinosinusal approach involves knowledge about the anatomy of this region, with a three-dimensional orientation before surgery, a therapeutic plan well thought, anticipating the gesture controller, taking into account the particularities of each case. Endoscopic surgical anatomic variants parts at this level can be well identified by imaging methods (CT, MRI). CT study of patients who are candidates for surgery Fess is on top, as the technique of choice. MRI is the imaging method to supply the CT data, providing a study carried out the normal anatomy and standard deviation of the numerous variants, single or in combination. This paper aims a randomized retrospective study of 120 MRI of the head and face region, to investigate and highlight the anatomical variations of structures at this level of impact and those with sinusitis etiopatologia, as well as those with operative risk (bleeding complications, ocular, vital risk) to determine the prevalence in the general population and have to compare the data with the literature. Using all sections (axial, sagittal and coronal) with the aid of different sequences (T1, T2, Flair and diffusion) allowed study of three-dimensional images of whole rhino-sinus-related pathology. Anatomic variations of surgical landmarks have investigated a wide range of expression, which are unique or associated with a complex architecture, with sufficient accuracy and visible on MRI. Their prevalence in the group studied was generally consistent with the literature studied. **Key words**: MRI, ANATOMIC VARIANTS, PARTS RHINO-SINUS SURGERY

THE RELATIONSHIP BETWEEN SOIL QUALITY, SECONDARY METABOLITE CONTENT AND ANTIOXIDANT EFFICACY IN *CARTHAMUS TINCTORIUS* L. AND *CALENDULA OFFICINALIS* L.

CARTHAMUS TINCTORIUS L. AND CALENDULA OFFICINALIS L.: NATURAL SOURCE OF ANTIAGING AGENTS FOR COSMETIC FORMULATIONS (Abstract): Asteraceae plants are commonly used for their antibacterial, anti-inflammatory and anti-aging effects. They are widely utilized in therapeutic and cosmetic formulations, while also serving decorative purposes. Safflower also serve a range of purposes, from medicine, food coloring and ornaments. *Calendula officinalis* is widely cultivated for medicinal and cosmetic purposes, especially for its therapeutic effects in topical formulations. Thus, the **aim** of our study was to investigate the influence of soil fertility on the secondary metabolites profile and its antioxidant activity. **Materials and methods:** To achieve this, *Calendula officinalis* and *Carthamus tinctorius* were cultivated in Romania under two different conditions: local soil, and enriched soil respectively. After collection, fragments of dried leaves and inflorescences were extracted with either ethanol or acetonitrile and analyzed. Semiquantitative analysis was performed using the HPLC method and he total phenolic content of each sample was quantified with Folin-Ciocalteu reagents. For the *in vitro* tests, 2,2-diphenyl-1-picryl-hydrazyl-hydrate (DPPH) was used to evaluate the radical scavenger activity, and reaction with ferrozine was used to evaluate the ferrous iron chelation capacity. **Results**: The quantitative analyses showed a clear influence of soil fertility on polyphenolic profile, impacting the antioxidant activity. **Conclusions:** The timing of harvest and the soil quality should be taken into consideration in order to ensure optimal pharmacological effects. **Keywords**: *CARTHAMUS TINCTORIUS, CALENDULA OFFICINALIS,* PHENOLS, ALLERGENIC RISK, ALANTO-LACTONE.

INTRODUCTION

Secondary metabolites (SMs) identified in Asteraceae plants possess proven pharmacological effects, which are attributed to their phytochemical compounds, such as polyphenols, phenolic acids, flavonoids, acetylenes and triterpenes (1). The specific SMs profile is related to local environmental conditions and agro-techniques of cultivated plants (2). The Asteraceae are also a source of sesquiterpene lactones (SLs). Of those, alantolactone has been documented as one of the principal allergenic and sensitizing compounds in such species (3). Alantolactone (helenin, eupatal, inula camphor), an eudesmanolide derived from *Inu-*

la helenium, also has antibacterial, anti-helmintic, anti-inflammatory properties and has been studied as a novel antineoplastic agent (4-6). The plant-related allergy symptoms involve contact dermatitis, hay fever, asthma or even anaphylaxis. The typical routes of exposure include skin contact, eye contact, ingestion or inhalation (4). The evidence of cross-reactivity of Asteraceae species with other plants and anaphylactic reactions has been reported (4). Cross-reactivity can occur between plant allergens and food and pollen allergens, especially in patients sensitive to Asteraceae (4).

Species of this plant family are now widely utilized in cosmetic formulations (creams, soaps, shampoos), aromatherapy or massage, in professional care or folk medicine. This high usage leads to speculation that sensitization to Compositae will increase. Compositae containing cosmetics are thought to provoke allergic reactions in susceptible individuals because they contain SLs (4).

Carthamus tinctorius (Safflower) has been grown for various purposes: medicine, food coloring, ornamental, fabric dye, biofuel. It is adaptable to arid conditions worldwide (7). It has many beneficial effects, such as: anti-inflammatory, antioxidant, antitumor effects. Injectable formulas have been widely applied in clinics. Although this species is considered non-toxic and has negligible side effects, anaphylactic reactions to safflower injections have been reported. This annual plant is not very used in modern cosmetic products (8). Studies of extracts from seeds, stems, buds and flowers suggest the potential cosmetic of safflower has not yet been completely uncovered (9).

Calendula officinalis, usually known as common marigold, is widely cultivated and used for medicinal and decorative purposes (8, 10). Much scientific research has established that marigold has a wide spectrum of pharmacological effects (11, 12). Phenolic acids and flavonoids have been identified mainly from inflorescences (8, 13). Compounds of a sesquiterpene nature were also detected or isolated (13). Calendula cream and products have shown very few allergic and side effects (14). The European Commission accepted calendula as a safe cosmetic ingredient (15). Although sensitization to calendula and allergic contact reactions are observed, anaphylaxis incidents were only reported in the context of infusion of marigold after gargling (14). Special care must be taken by people who are allergic to species from the Asteraceae family when using or consuming preparations containing marigold extract or oil (14). Only flowers are commonly used, while the rest of the biomass is considered waste. Unfloral parts of the plant should also be taken into consideration (9).

This study aims to evaluate *Carthamus tinctorius* and *Calendula officinalis* as sources of antiaging agents for cosmetics related to their allergenic potential in cosmetic formulations. The allergenic risk factor considered consisted in assessing the presence and quantity of alantolactone in the plant. Total phenolic content was evaluated as a marker of antioxidant capacity. The two species were cultivated in local and enriched soil conditions, to evaluate their biosynthesis capacity for SLs and antiaging secondary metabolites. Aerial parts of plants were investigated, floral and unfloral, to study the potential of "waste" vegetal material as a source of natural products.

MATERIALS AND METHODS

Plant material. *Calendula officinalis*

and *Carthamus tinctorius* were cultivated in north-eastern Romania in the year 2015 under two nutritional statuses: local (V1) and enriched soil conditions (V2) with N-P-K (Mg) 15: 10: 12. The fertilizer was administered just before planting (75g/m^2). Rooted cuttings were planted at a density rate of 4 plants/m^2. Aerial parts of the plants were collected: fully bloomed inflorescences (F), leaves and stems, defined as unfloral aerial parts (L). The samples were codified as follows: V1F, V2F, V1L, V2L. Fresh aerial parts of plants were dried in a thermostatic oven at 35°C until three consecutive measurements turned out identical. Voucher specimens are deposited as DE-8425906 (marigold) and NL-62850040 (safflower) at the Department of Pharmacognosy ("Grigore T. Popa" University of Medicine and Pharmacy Iasi) for ready reference.

Extraction. Fragments (2 g) of dried leaves and inflorescences were extracted with methanol or acetonitrile R in the Laboratory of Pharmacognosy, Faculty of Pharmacy, "Grigore T. Popa" University of Medicine and Pharmacy Iasi, Romania. For polyphenol quantification, the methanolic extract was obtained (1:10, m/m) by repeated sonication for 15 minutes.

For alantolactone evaluation by HPLC, the test solutions were obtained in acetonitrile R (1.0 g powdered drug in 3 mL solvent, three times, sonicated for 15 minutes). The filtrates were reunited and brought to 10 mL in a volumetric flask. A quantum of 0.20 µL was used for HPLC analysis.

Total phenolic content determination. The total phenolic content of each sample was quantified with Folin-Ciocalteu reagent according to the Singleton and Rossi method (1965), using gallic acid as a standard (16). The measurements were performed on ABLE-JASCO V 550 UV-VIS spectrophotometer. The absorbance was measured at 765 nm versus blank samples. The blank consisted of samples and all reagents and solvents except sodium carbonate. The results were expressed as mg gallic acid equivalents (GAE)/100 g dried sample.

HPLC analysis. Semiquantitative analysis of alantolactone was performed using the HPLC method described by Ivănescu (2015) with modifications (18). The method was adapted for a Thermo-Fischer UltiMate 3000 system coupled with DAD detector used to assess the profile of sesquiterpene lactones. The working conditions were: Accucore XL-C18 column (4.6 x 150 mm, 4 Wm); column temperature: 34 °C; detection wavelength was set at 225 nm and the flow rate was 1.2 mL/min. The mobile phase consisting of two eluents as A (water) and B (methanol) used the following linear gradient elution: 0-3 min 38% B; 3-20 min 45% B; 20-30 min 45% B; 30-55 min 55% B; 55-57 min100% B; 70 min 100% B; 90 min 38% B. As standard, alantolactone was used in the amount of 20 µL of a 5 mg/mL solution. Five consecutive injections were done for repeatability purposes. Samples UV spectra registered at 225 nm were automatically compared by Chromeleon 7.2 software and the concentration was expressed as % of the standard's area/concentration.

Antioxidant activity. For the *in vitro* tests, 2,2-diphenyl-1-picryl-hydrazyl-hydrate (DPPH) was used to evaluate the radical scavenger activity. The test was performed using the method of Hatanao *et al.* For each sample EC50 value (expressed in µg extract/mL) was calculated by plotting the radical scavenger activity variation and the concentration of the extract. Gallic acid

was posed as positive control (20). The scavenger activity was determined according to the formula:

$$\% \text{ activity} = (A_{DPPH}-A_P) \cdot 100/A_{DPPH}$$

where ADPPH represents the absorbance of alcoholic DPPH solution, AP represents the absorbance after 10 minutes of DPPH solution treated with methanol extract.

The ferrous iron chelation capacity was also evaluated. When reacting with ferrozine, Fe^{2+} forms a pink-colored complex, exhibiting maximum absorbance at 562 nm. The presence of a chelating agent in the reaction medium results in reduced absorbance of the complex, causing a decrease in the solution's color intensity (21).

All reagents were of analytical purity and were purchased from Sigma Aldrich (St. Louis, MO, USA). All measurements and analyses were performed in triplicates. The variants were compared with their average. Data for quantitative and semi-quantitative analytical determinations were presented as mean values ± standard deviations.

RESULTS AND DISCUSSION

Total phenolic content. Flavonoids and polyphenolic derivatives are proven natural antioxidants. Phenolic content reflects the potential of investigated Asteraceae to have important value as a source of anti-ageing compounds. Analysis of samples from different nutritional plant status pointed out the capacity of plant biosynthesis for SMs depending on local and enriched soil conditions.

The literature data confirm the polyphenolic contents in marigold flowers (11), especially in safflower oils, worldwide (10, 11, 17). As it can be seen from Table I, the amount of phenols differs between samples.

Carthamus has approximately double phenolic content in leaves and stems of unfertilized plants in comparison with flowers. Enriched soil conditions will increase total phenols in flowers, but decrease their total phenols in the aerial parts level. Total phenols in *Carthamus* are similar with quantities found in *Echinacea purpurea* cultivated in similar biotic conditions (18), but lower than the amounts of phenols found in *Tagetes erecta* and *Rudbeckia hirta* (19). The results point out the important role of biomass (leaves, stems) as a source of phenolic compounds from unfertilized cultivated safflower in circular economy.

TABLE I.

Total polyphenols determined in *Carthamus tinctorius* and *Calendula officinalis* (mg GAE/100 g dried sample)

Sample	V1F	V2F	V1L	V2L
Carthamus	145.79± 0.25	228.91± 0.52	276.07± 0.43	204.39± 0.50
Calendula	160.62± 0.35	189.41± 0.22	198.77 ± 0.40	124.36± 0.38

Similar to that of *Carthamus*, the polyphenolic content of marigold leaves and stems is greater in comparison with content determined in flowers in unfertilized plants. This emphasizes the economic importance of "vegetal waste" obtained from crops cultivated especially for flowers. The fertilization increases phenolic content in flowers but not in the aerial parts.

Alantolactone content. Proven aller-

gen, alantolactone presence is confirmed in marigold and safflower in our study (tab. II). The quantity of alantolactone detected in samples is greater in unfertilized plants, both in flower tops and in the aerial parts. On a general note, flowers have smaller quantities of alantolactone in comparison with leaves and stems in safflower and marigold. That could explain the low allergenic potential of flower tops. The risk of allergen reactions still exists in patients with known allergies.

TABLE II.

Semiquantitative determination of alantolactone in *Carthamus tinctorius* and *Calendula officinalis* (µg %)

Sample	V1F	V2F	V1L	V2L
Carthamus	0.1740	0.1561	0.6568	0.5333
Calendula	0.2414	0.0213	6.0045	0.0438

Marigold aerial parts of unfertilized plants have large amounts of alantolactone (V1L). This data suggests that the leaves and stems could be a potent source of alantolactone. The quantities found in our study are superior to data published on other ornamental Asteraceae cultivated in eastern Romania (19). On the other hand, these data could explain the low allergenic profile of marigold flower, but also point out a high allergenic risk for people who handle the crops or vegetal material.

Antioxidant capacity of the investigated samples. The obtained results for the antioxidant assays are given in third table and indicate that the nutritional status of the soil influences the biosynthetic capacity of the plant. Moreover, the accumulation pattern of secondary metabolites with antiradical potential is similar for both species, and increases in the flower tops of the fertilized group.

TABLE III.

The antioxidant potential of *Carthamus tinctorius* and *Calendula officinalis* samples against DPPH and iron radicals

Sample	V1F	V2F	V1L	V2L
DPPH inhibition (IC50, µg/mL)				
Carthamus	105.2±1.84	37.4±0.56	43.1±0.96	89.5±1.13
Calendula	147.3±0.96	100.2±1.04	128.2±0.67	213.7±0.07
Iron chelation (IC50, µg/mL)				
Carthamus	460.1±0.87	310.3±0.04	242.6±1.04	712.3±0.24
Calendula	228.2±1.02	184.2±0.16	237.1±0.82	378.6±0.09

According to our results, the investigated samples have a good effect against free radicals, but much lower if compared to gallic acid that had a value of IC50 at 1.15 µg/mL for DPPH assay, and 6.65 µg/mL for iron chelation assay. Also, the variation of the activity is directly correlated to the polyphenolic content. Interestingly, for *Carthamus* flowers the iron chelation inhibition is much lower than the capacity to

quench DPPH radicals.

Considering that the oxidative stress is a multifactorial complex process cell membrane are exposed to, the use of cosmetic applications that include natural components with antioxidant potential should prevent the degradation induced by such factors (2, 7, 22, 23). Polyphenols are compounds recognized for their antioxidative and protective activities, therefore they have been used for various preparations (22). Both marigold and safflower represent important raw materials for pharmaceutical and cosmetics industries and the quality of the plant products have a direct impact on the benefits given by the final products (2, 22). This is why the chemical composition and the antioxidant capacity of the plant material is extremely important for further development of different preparations.

Another important aspect is shown by the low quantity of alantolactone in the flower tops of the both investigated species, which indicates that harvesting should be done at the complete maturity when terpene lactones decrease and total phenols accumulate in higher amounts. This will ensure a low allergenic profile and a good protective potential of the formulations obtained from the flower material.

CONCLUSIONS

The studied Asteraceae cultivated in NE Romania are a potent source of polyphenols and could be a natural source of anti-aging agents in cosmetics. The allergenic risk of calendula and carthamus flowers extracts is low as confirmed by HPLC analysis. The allergic potential is greater in the unflower aerial parts of the plants, especially in the marigold. The use of flowers as raw materials for cosmetic formulation is generally safe. The biomass of nonflower aerial parts has very important economic value as a natural source of polyphenols (*Carthamus*) and alantolactone (*Calendula*). Our data confirm that vegetal "waste" is an important source for secondary metabolites. Other studies are needed to extend these findings.

RELATIONSHIP BETWEEN LEVELS OF STREPTOCOCCUS MUTANS AND SOCIOECONOMIC STATUS OF SCHOOLCHILDREN IN IASI, ROMANIA (Abstract). **Aim:** To evaluate the dental and salivary level of *Streptococcus Mutans* among Iasi schoolchildren in relationship with their family socioeconomic status. **Material and methods**: This cross-sectional study included 533 schoolchildren aged 7-12 years from Iasi town. The level of *Streptococcus Mutans* on dental surfaces (mesial and occlusal surfaces of the molars 1.6 and 3.6) and in saliva was assessed using Dentocult® SM Strip mutans kits (Orion Diagnostica Oy) according to manufacturer's instructions. Subjects were given one of the following scores: 0 = $<10^4$ CFU/ml; 1 = $<10^5$ CFU/ml; 2 = 10^5–10^6 CFU/ml; 3 = > 10^6 CFU/ml. Parental occupation, income and number of children in the family were considered for the assessment of the socioeconomic status. **Results**: Score 0 was predominant both in saliva and on the mesial and occlusal surfaces of first permanent molars of children of high socioeconomic status. Scores 2 and 3 were predominant in children of medium socioeconomic status, while score 3 was predominant on dental surfaces and in the saliva of children of low socioeconomic status. **Conclusions**: Children from families with low socioeconomic status have a higher prevalence of increased levels of *Streptococcus Mutans*, as compared to children from families with high socioeconomic level, underlining the need for complex prevention programs that should reduce inequalities in children oral health status caused by socioeconomic factors. **Keywords**: SCHOOLCHILDREN, STREPTOCOCCUS MUTANS, SOCIOECONOMIC STATUS.

Pointing out the risk factors for oral diseases enables the identification of their role in oral health. Knowledge about the population distribution of those factors is an essential step in developing preventive strategies and in planning preventive oral healthcare services.

Numerous studies have shown the correlation between parental social status and oral health status of children. In Romania, despite the fact that all children receive free dental services through the National Health Insurance, there are marked inequalities in oral health. Besides the social aspects, parents' oral health education level plays an important role.

The aim of the present study was to comparatively evaluate the dental and salivary level of *Streptococcus Mutans* (*SM*) among schoolchildren in Iasi town,

depending on the socio-economic status (SES) of their families.

MATERIAL AND METHODS

The cross-sectional, clinical and microbiological study was conducted between May 2015 and September 2016. The following criteria were considered for the selection of the study sample: children aged 7 to12 years; children attending schools in various districts of Iasi town; schools in which a dental office was available. The sample was selected using the probabilistic method and included 533 children (50.47% males and 49.53% females). Clinical examinations were performed in the dental offices of the selected schools.

The level of *SM* on dental surfaces (mesial and occlusal surfaces of the molars 1.6 and 3.6) and in saliva was assessed using Dentocult® SM Strip mutans kits (Orion Diagnostica Oy), according to manufacturer's instructions. For the assessment of dental *SM* level, special tips were used to obtain bacterial plaque samples, which were subsequently spread on the four sites of the square-tipped strips. For salivary *SM* evaluation, the patient was invited to chew a paraffin pellet for 1 minute, then the rough surface of the round-tipped strip was pressed against the saliva remaining on patient's tongue. The two strips were then placed in the selective culture broth; the vials were incubated at 35-37°C for 48 h; after incubation, the density of the grown colonies was compared to the chart provided by the producer, according to the following scores: 0 = $<10^4$ CFU (colony-forming unit)/ml; 1 = $<10^5$ CFU/ml; 2 = $10^5 – 10^6$ CFU/ml; 3 = > 10^6 CFU/ml.

Tests were performed at least 1 h after eating and toothbrushing, in a distinct dental visit and not during a treatment session; patients on antibiotic therapy during the last month before testing were excluded.

The socioeconomic status of the family (SES), established as low, medium or high, was assessed considering parents' occupation, income and number of children in the family. A balanced distribution of the subjects belonging to the three socioeconomic levels was ensured in the study sample.

Children participation in the study was conditioned by parental written consent. Children also had the opportunity to accept or refuse participation.

Data privacy as well as the impossible identification of subjects in the case the results are published were guaranteed.

SPSS 17.0 was used for the statistical analysis of data. The statistical significance threshold p was set at 0.05; chi-square test was used for data comparison and correlation analysis was performed using Spearman test.

RESULTS

Analysis of data obtained from the bacteriological tests for the evaluation of dental levels of *SM* indicated that score 3, meaning a density of more than 10^6 CFU/ml was predominant both on the mesial surfaces of 1.6 and 3.6 and on the occlusal surfaces of the same teeth.

Comparative evaluation depending on SES indicated significant differences in *SM* number; on the dental surfaces, such differences were observed particularly on the mesial surfaces of first permanent molars (1.6) (tab. I). Score 0 was predominant in children of high SES (48.8%), while score 2 prevailed in children of medium SES (35.1% for upper teeth 1.6 and 36.8% for lower teeth 3.6) and score 3 - in the group of low SES (56.2% and 63.6%, respectively).

TABLE I

Children distribution (%) depending on *Streptococcus Mutans* scores on mesial surfaces of the teeth and socioeconomic status

Score	*Situs*					
	Mesial surface 1.6			Mesial surface 3.6		
	Low SES	Medium SES	High SES	Low SES	Medium SES	High SES
0	10.8	21.1	48.8	10.8	21.1	48.8
1	4.5	12.4	20.3	4	14.6	20.3
2	28.4	35.1	27.3	21.6	36.8	27.3
3	56.2	31.4	3.5	63.6	27.6	3.5

Chi-square statistical test showed that the differences were statistically significant at a threshold of 0.01, and the correlation between *SM* number on the mesial surfaces of first permanent molars (1.6) and SES was strongly inversely proportional (Spearman coefficient r = -0.510 and r = -0.539, respectively).

Such differences, but slightly reduced, were observed in the number of *SM* on the occlusal surfaces (tab. II): score 0 was predominant in children of high SES (47.1%), while score 3 prevailed in children of low and medium SES (58.5%, 56.2% and 44.3%, 35.7%, respectively).

Differences remained statistically significant ($p < 0.01$) and the correlation between the number of *SM* on the occlusal surfaces of first permanent molars (1.6) and SES was still inversely proportional, but moderate (r = -0.456 and r = -0.471, respectively).

TABLE II

Children distribution (%) depending on *Streptococcus Mutans* scores on occlusal surfaces and socioeconomic status

Score	*Situs*					
	Occlusal surface 1.6			Occlusal surface 3.6		
	Low SES	Medium SES	High SES	Low SES	Medium SES	High SES
0	10.8	21.1	47.1	10.8	21.1	47.1
1	1.7	15.1	20.3	4.5	14.6	20.9
2	29	19.5	20.9	28.4	28.6	23.8
3	58.5	44.3	11.6	56.2	35.7	8.1

Among the most important differences in caries risk factors between children of different socioeconomic levels were those in the number of salivary *SM* (tab. III); nearly 50% of the subjects of high SES presented score 0, while in those of low SES scores 2 and 3 were predominant (29.5% and 54%, respectively).

TABLE III

Children distribution (%) depending on *Streptococcus Mutans* salivary scores and socioeconomic status

Score	Low SES	Medium SES	High SES
0	10.8	21.1	48.8
1	5.7	15.1	24.4
2	29.5	38.9	23.8
3	54	24.9	2.9

Chi-square analysis indicated statistically significant differences ($p < 0.01$). Spearman correlation coefficient showed an inverse, strong correlation: *SM* salivary level increases as SES decreases ($r = -0.521$).

DISCUSSION

One of the greatest challenges of public health systems in the XXI century is represented by detecting and reducing inequalities in oral health status of the population (1, 2). Reasons for disparities in oral health are complex. There are differences caused by biological factors (e.g. gender, age), their existence being normal and unavoidable in a balanced society.

However, there are avoidable inequalities that are unacceptable in modern society, caused mainly by socioeconomic differences (3). Studies have shown that, over the last decade, differences in health between individuals of high and low socioeconomic level have increased (4).

Given these considerations, the present study analyzed the influence of the family socioeconomic level on the salivary and dental level of *SM*. Comparative assessment and use of statistical correlation tests showed that there were statistically significant inequalities in terms of *SM* density caused by SES. Among high SES children, score 0 of *SM* density was predominant both in saliva and on the mesial and occlusal surfaces of first permanent molars (1.6). Scores 2 and 3 were predominant in medium SES children, while score 3 of dental and salivary *SM* prevailed among low SES subjects.

Of the four major categories of factors that influence oral health (environmental factors, biological factors, behavioral factors and dental care system), social environmental factors have the greatest impact (5). The results of the present study confirm it by the evident differences in *SM* levels according to the socioeconomic level.

The most plausible explanation for these discrepancies is the behavioral differences related to oral hygiene habits and healthy diet. Although behaviors towards oral health, including various types of behavior, cannot be influenced by the same social and economic variables, two of the most important behaviors in terms of etiology of dental caries, i.e. brushing and sugar consumption are directly correlated with income level, educational level and occupational status (6). High SES individuals usually have a higher level of oral health knowledge and good oral health behaviors, mainly due to the improved access to information means (7). In addition, their income allows them to access more expensive hygiene products and healthy foods.

Results consistent with those obtained in this study were highlighted by other studies in the literature. In a study that assessed oral colonization of small children with *SM* it was found that mothers of children infected with this microorganism showed increased levels of salivary *SM*, poor oral hygiene and a low socioeconomic level (8, 9).

Parental educational level plays an important role in oral hygiene status of their children and, thus, in the level of cariogenic microorganisms. Studies conducted in this regard have shown higher *SM* levels among adolescents from families with low education level (7).

The impact of SES on the level of cariogenic microorganisms is further reflected in the level of dental caries. Numerous studies showed that lower-class children experience more caries. Children of highly educated, professional and high income parents are at lower risk for dental caries (10).

Socioeconomic level impacts on many of the healthy oral behaviors. The more likely they visited a dentist for routine checkup, the higher the SES, the less frequently they had sweets, and the lower the SM level, the more likely they were caries-free and the less likely they were to have a high DMFT (11).

Contamination with *SM* increases the risk of caries development. However, this risk can be partially offset by other factors, with protective role, including good oral hygiene and non-cariogenic diet. On their turn, these factors can counterbalance each other, meaning that cariogenic diet does not necessarily lead to the emergence of caries, provided that rigorous oral hygiene is ensured (12).

CONCLUSIONS

Children from low SES families have a higher prevalence of increased *Streptococcus Mutans* levels, as compared to children from high SES families, underlining the need for complex prevention programs that should reduce inequalities in children oral health status caused by socioeconomic factors.

THE ANALYSIS OF THE PERSONAL VARIABLES AMONG THE ROAD TRAFFIC CASUALTIES TAKEN OVER BY THE IASI COUNTY AMBULANCE SERVICE, ROMANIA (Abstract): In last three years (2013-2015) the Ambulance Service of Iași, the largest county from the North-East region of Romania, provided emergency care to 4,028 road traffic injured persons, after the 112 Single Emergency Call Number has been dialed. **Aim**: This paper describes the main personal characteristics of the road traffic casualties taken over by the Ambulance Service, to design a profile of the injured persons, on whose foundation, specific protective measures regarding the road traffic injuries could be developed. **Materials and methods:** The survey is based on a descriptive analysis of the 4,028 cases forwarded by the central dispatch to the Iasi County Ambulance Service. The data source was provided by the Iasi County Ambulance Service and conceived of the emergency care files of the injured persons. The analysis of the personal variables was based on: demographic issues, the categories involved in road accidents and the patient's status at the crash scene. **Results:** More male (61.7%) were injured than female, the male: female ratio of injuries being 5/3. Of the total 4028 cases recorded along the three years, 806 were young people aged 20-29 years and of these, male subjects represented 74.2%. A strong negative correlation was found between age and the number of subjects by age groups (r = -0.96). More than two thirds (68.7%) of the total sample are living in urban area, the urban/rural ratio being 2/1. Car occupants represented 91.7% of the total injured cases, followed by the motorized 2-wheelers drivers (4.7%), pedestrians (1.5%), wagon drivers (1.1%) and cyclists (1%). Approximately two persons of one hundred casualties (1.9%) were found deceased at the scene of the crash. The severe unconscious cases and the deceased combined accounted 6% of all cases. An analysis of the fatalities by gender pointed out a higher death rate among male (2.9%), compared to 0.4% among female, the difference being strong significant ($p<0.001$). The repartition of the total deaths by road user category placed on the first place the car occupants (52.6%), followed by motorized 2-wheelers drivers (23.1%), pedestrian (20.5%) and wagon drivers (3.8%). The severity of the injury has been assessed and revealed four risk factors: male gender, pedestrian, cyclist and motorized 2-wheelers. The odds ratio values ranged from 8.19 for pedestrians to 2.81 for motorized 2-wheelers drivers. **Conclusions**: All these findings allow a profile of the people affected most frequent by the road traffic injuries, representing casualties taken over by the Iasi County Ambulance Service in the interval 2013-2015: young male, aged 20-29, urban resident, car occupant. The most severe cases were found among male of three road user categories: pedestrian, cyclist and motorized 2-wheelers. **Keywords**: AMBULANCE SERVICE, ROAD TRAFFIC INJURY, PERSONAL VARIABLES.

In the road traffic injuries, the access to the emergency medical system is most frequently made by telephone, dialing 112, the Single Emergency Call Number. The next step in the post-impact chain interventions from crash scene to hospital is delivering of the emergency care at the place of the collision and getting victims as soon as possible to a health-care facility (1). Because of many road crashes are avoidable, the descriptive epidemiology data are essential for the preventive measures related to the human safety (drivers, passengers, pedestrians), and as severity predictors in a crash injury (2).

This paper describes the main personal variables of the road traffic casualties taken over by the Ambulance Service of Iasi, the largest county of the North-East Romania, along an interval of three years (2013-2015). The analysis of these data allows the elaboration of the profile of the injured persons, on whose foundation, protective measures regarding the accidents and the traumas could be developed, to reduce complications, but mainly to prevent other deaths.

MATERIALS AND METHODS

The survey is based on a descriptive analysis of the cases forwarded by the central dispatch to the Iași County Ambulance Service, after the 112 Single Emergency Call Number has been dialed and the provision of emergency care to people involved in road traffic accidents in Iași County has been requested.

The data source was provided by the Iași County Ambulance Service and conceived of the 4028 emergency care request files of persons involved in road traffic accidents and who received emergency care during 2013-2015. The analysis of the personal variables was based on: demographic issues (age, gender and residence area), the categories involved in road accidents (pedestrians, cyclists, wagon drivers, tram drivers, car drivers, motorcyclists) and the patient's status (deceased, conscious, unconscious).

The database and the statistical analysis were done in *EpiInfo TM 7*.

RESULTS

During 2013-2015, the Iasi County Ambulance Service reported a total number of 392,267 calls, of which 4,028 represented road traffic injuries. Each year, the share of the road crashes casualties was approximately 1% of the total. The number of injured persons increased with 52.07%, from 1,085 in 2013 to 1650 in 2015.

The burden of injury by gender was unequal (tab. I). More male (61.7%) were injured than female, the male: female ratio of injuries being 5/3.

Of the total 4,028 cases recorded along the three years, 806 were young people aged 20-29 years (fig. 1) and of these, male subjects represented 74.2%. This proportion corresponds to a male: female ratio of 3/1 and in an analysis by decennial age groups, is the highest value in" favor" of male. On average, in Iasi County, yearly, the Ambulance Service delivered emergency care to 268 young people belonging to the third decade of life and who sustained a road crash injury (tab. II).

The average age for all injured persons was 35.6±19.6 years (range 1-91years). A strong negative correlation was found between age and the number of subjects by age groups (r = -0,96).

Another personal variable was the residence area of the road traffic injured cases. The annual average of the injuries in rural was 419.6 ± 118.5, whereas in urban was 923 ± 167.5. More than two thirds (68.7%) of the total sample are living in urban area, the urban/rural ratio being 2/1.

TABLE I

Data on the breakdown by gender

Year	Male		Female		Total
	No.	%	No.	%	
2013	641	59.07	444	40.93	1085
2014	777	60.09	516	39.91	1293
2015	1068	64.7	582	35.3	1650
Total	2486	61.7	1542	38.3	4028

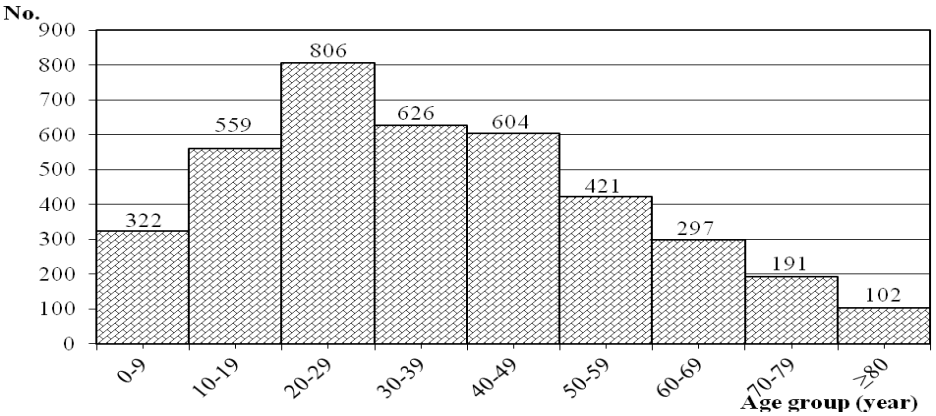

Fig. 1. Age group distribution of the total sample of road traffic injuries

TABLE II

Distribution by year and age group

Age group (yrs.)	2013	2014	2015	Annual average ± SD
0-9	93	105	124	107.3 ± 15.6
10-19	126	208	225	186.3 ± 52.9
20-29	254	288	264	268.6 ± 17.4
30-39	165	194	263	207.3 ± 50.3
40-49	143	200	261	201.3 ± 60.5
50-59	122	131	168	140.3 ± 24.3
60-69	76	78	143	99.0 ± 38.1
70-79	76	50	65	63.6 ± 13.0
≥ 80	31	40	31	34.0 ± 5.1

The profile of the people affected by road traffic injuries was assessed due to important differences between various road user groups. On average, each year, 1270 people traveling with a 4-wheeled car sustained a road crash injury (tab. III).

They represented 91.7% of the total, followed by the motorized 2-wheelers drivers (4.7%), pedestrians (1.5%), wagon drivers (1.1%) and cyclists (1%).

TABLE III
Data on the breakdown by road user category

Road user category	Cumulative number	Annual average ± SD
Car occupants	3695	1270.3 ± 204.2
Motorized 2-wheelers	188	60.6 ± 6.5
Pedestrians	61	15.6 ± 4.2
Wagon drivers	45	14 ± 5.4
Cyclists	39	13 ± 4.1

When delivering emergency care at the scene of the crash, the ambulance professionally trained staff make firstly a complete evaluation of every injured person, to identify life-threatening injuries. Approximately two persons of one hundred casualties (1.9%) were found deceased at the scene of the crash. The severe unconscious cases and the deceased combined accounted 6% of all cases (tab. IV).

TABLE IV
Patient's condition at the scene of the crash

Patient's condition	Cumulative number	Annual average ± SD
Conscious	3785	1263.6 ± 280.4
Unconscious	165	55 ± 13
Deceased	78	26 ± 4.5

An analysis of the fatalities by gender pointed out a higher death rate among male (2.9%), compared to 0.4% among female, the difference being strong significant ($p<0.001$). A similar situation has been recorded for the unconscious cases (male 5.5%, female 1.8%, $p<0.001$).

The repartition of the total deaths by road user category placed on the first place the car occupants, followed by motorized 2-wheelers drivers, pedestrian and wagon drivers, as shown in fig. 2. Car occupants were the first largest group of road users killed and found by the ambulances at the scene of the crash.

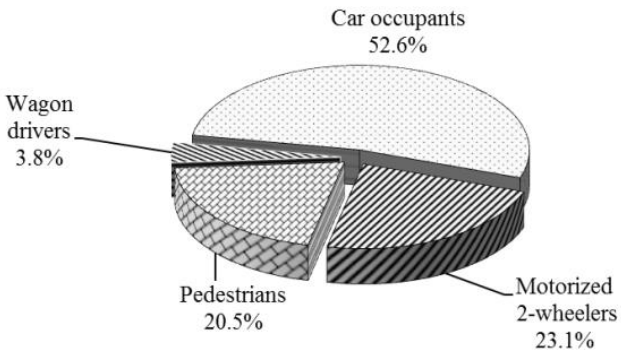

Fig. 2. Distribution of the total deaths by the road user category

The fatality rate among different road user groups was 26.2% for pedestrians, 9.6% for motorized 2-wheelers drivers and 6.6% for wagon drivers. The lowest fatality rate (1.1%) was found at the vehicle occupants. No deaths were recorded in the cyclists group.

The severity of the injury has been assessed by comparing the personal variables among the conscious cases with the unconscious and deceased cases. The analysis revealed four risk factors for a severe prognosis: male gender, pedestrian, cyclist and motorized 2-wheelers. The odds ratio values ranged from 8.19 for pedestrians to 2.81 for motorized 2-wheelers drivers (tab. V).

TABLE V

Risk factors for a severe prognosis among the injured road users

Risk Factor	Unconscious +	Conscious	Odds	IC_{95}	p value
Pedestrians	20	41	8.19	4.71-14.21	<0.001
Male gender	209	2277	6.54	4.19-10.19	<0.001
Cyclists	7	32	5.19	2.25-11.95	0.001
Motorized 2-wheelers	27	161	2.81	1.83-4.32	<0.001

DISCUSSION

In the interval 2013-2015, the number of injured persons involved in road traffic accidents and taken over by the Iasi County Ambulance Service increased with 52.1%.

Injury rates and mortality rates are higher in men than in women across all age groups. The gender difference may be related to both exposure and risk-taking behavior.

Adults aged between 20 and 49 years' account for more than 50% of all road traffic injuries. In an analysis by decennial age groups the highest value was recorded among young people in their third decade of life (20%). The number of cases for older persons over 60 years was, on average, less than 100 per year, due to the lower rate of exposure they experience.

Road traffic crashes are more frequent in urban areas, as urbanization increases (3,4). According to this fact, in this study, people from urban area sustained twice more often road trauma compared with rural area.

Among the various categories involved in road accidents, car occupants (drivers and passengers) accounted more of 90% of injured persons and more of 50% of deaths found by the ambulance at the scene of the crash. Despite these values, the fatality rate among car occupants was low (1.14%), compared to the motorized 2-wheelers drivers, pedestrians, wagon drivers and cyclists, they often bearing the greatest burden of the injury.

Crashes between vehicles and pedestrians are responsible for many deaths in this category of road users (5,6). In terms of fatality rate, one of four injured pedestrians were found dead at the scene of the crash (26.2%). This was the highest fatality rate, followed by the motorized 2-wheelers (9.5%) and wagon drivers (6.6%). They represented the most vulnerable groups, compared to the vehicle occupants, being far the most exposed group.

All these findings allow a profile of the people affected most frequent, but nonfatal, by the road traffic injuries, representing casualties taken over by the Iasi County Ambulance Service in the interval 2013-

2015: young male, aged 20-29, urban resident, car occupant.

In the same time, by calculating the Odds Ratios for various personal variables, a profile of the most severe case was designed: male gender, pedestrian, cyclist or a 2-wheels vehicle rider.

CONCLUSIONS

Along an interval of three years (2013-2015), the Iasi County Ambulance Service provided emergency care to 4,028 road traffic injured persons. The number of injured persons increased from 2013 to 2015 with 52.07%

The proportion of males exceeded females (61.7%), the male: female ratio for injuries being 5/3.

One of two injuries were an adult aged between 20 and 49 years and one of five was in the third decade of life.

More than two thirds (68.7%) of the total sample are living in urban area, the urban/rural ratio being 2/1.

Car occupants (drivers and passengers) accounted more of 90% of injured persons and more of 50% of deaths found by the ambulance at the scene of the crash, but the fatality rate among car occupants was low (1.14%).

The highest fatality rate was recorded among pedestrians (26.2%), followed by the motorized 2-wheelers (9.5%) and the wagon drivers (6.6%).

The typical road traffic injury to which the Iasi County Ambulance Service provided emergency care was: young male, aged 20-29, urban resident, car occupant.

The analysis of the injuries' severity based on the Odds Ratios, allowed the identification of the following personal variables: male gender, pedestrian or a 2-wheels vehicle rider.

Various protective measures, such as making walking safer or paths for wagons, are critical to decrease the number of road traffic injuries, to reduce complications and to prevent deaths.

NEW NITRIC OXIDE DONORS WITH THERAPEUTIC POTENTIAL (Abstract): Nitric oxide (NO), formerly known as the endothelium-derived relaxing factor, is a mediator with a key role in the body, both in the central nervous system and in periphery. NO is synthesized by several cell types, where it acts as an autocrine and paracrine signaling molecule. Harnessing the impressive therapeutic potential of nitric oxide (NO) remains an ongoing challenge. In order to overcome the limitations linked with the use of nitric oxide and specially to increase the release of the radical in the targeted area, promising therapeutic strategies have been implemented, based on specific technologies which create releasing agents and vehicles for nitric oxide. Organic nitrites are the most known NO donor drugs, used especially in the treatment of cardiovascular diseases. In recent years, technological advances have allowed obtaining variations synthetic derivatives (such as diazeniumdiolates, S-nitrosothiols), which can generate NO in a controlled mode in the body and to chemically stabilize it; these compounds were studied with promising results in various animal models of vasospasm and pulmonary hypertension. Another high value therapeutic path is represented by the development of hybrid drugs (new nonsteroidal anti-inflammatory NO donor agents), with practical applications in inflammatory disorders accompanied by pain. Also, there is increasing evidence of the existence of NO donors with important antioxidant and hepatoprotective effects. **Keywords:** NITRIC OXIDE, NO DONORS, DIAZENIUMDIOLATES, *S*-NITROSOTHIOLS.

During the 1980s, the free radical nitric oxide (NO) was discovered to be a crucial signaling molecule, with a variety of pharmacological activities in the cardiovascular, nervous and immune systems. In 1992, the free radical nitric oxide was awarded the title 'molecule of the year' (1).

Formerly known as the endothelium-derived relaxing factor, nitric oxide (NO) has been intensively studied over the years, its importance in the body being fully recognized in 1998 when the Nobel Prize for medicine was awarded to a team of researchers for their studies on the biological effects of this molecule (2). Despite its structural simplicity, NO plays an active role in complex and varied biological processes. An important fact is that its sphere

of influence is likely to extend to only ~100 μm from its origin. This property has important consequences: first, it means that NO must be rapidly synthesized on demand in response to stimuli and second, it is a local mediator that does not require complex metabolism for clearance; it is simply oxidized to nitrite/nitrate as it diffuses away from its source (3). Therefore, an important property of NO, which distinguishes it from other mediators of the central nervous system, is diffusivity. This is increased in both the aqueous and the lipid media, providing a three-dimensional spreading signal, regardless of the presence of membranes (4).

The most studied actions of NO are on the cardiovascular system, where it is continuously produced by the endothelial cells that line the lumen of blood vessels. Here, L-arginine is converted into NO by the endothelial isoform of the enzyme NO synthase, in response to mechanical and chemical stimuli that act by mobilizing intracellular calcium.

NO diffuses away from the cell of origin, passing easily through membranes of neighboring cells, bringing on a range of physiological effects. NO participates in maintaining and regulating blood pressure, due to its role in adjusting systemic vascular resistance (5, 6).

NO acts almost exclusively in vascular smooth muscle cells (3) via the soluble enzyme guanylate cyclase, stimulating cyclic guanosine-3',5'-monophosphate (cGMP) production and elicit vasodilation via cGMP-dependent protein kinases. Also, NO has an impact on circulating platelets, where, in response to endothelium and platelet-derived NO, both cGMP-dependent and independent mechanisms play a part in its powerful inhibitory effect on aggregation and adhesion (7, 8).

Considering that a characteristic of many cardiovascular diseases is the reduced level of NO in the soluble guanylate cyclase pathway, an intake of exogenous NO would be a possible and attractive therapeutic choice (6, 9).

NO donors in the cardiovascular disease

The translation of therapeutic potential of NO to bedside has been slowed down by its short biological lifetime, instability during storage and potential toxicity. Taking these into account, new drugs have been obtained, with the role of molecular NO vehicles (also named *NO donors*), created for stabilizing this radical, until the moment when it needs to be released (10). Increased understanding of the essential role of nitric oxide (NO) in various physiological processes and diseases has stimulated the development of multiple pharmacologic strategies to release NO at the involved level of pathogenic pathways (11). These approaches include therapies that directly or indirectly release or “donate” NO and the use of existing drugs, such as antihypertensive agents (e.g. nebivolol) and 3-hydroxy-3-methylglutaryl coenzyme A reductase inhibitors (statins) which enhance NO bioactivity in the body (12).

Capitalizing on the biological actions of NO, these therapeutic strategies are providing new insights into the pathogenesis and treatment of various diseases, including hypertension, atherosclerosis, cancer, Alzheimer's disease, colitis and asthma (3, 13).

The organic nitrites are the most commonly used NO donor drugs: glyceryl trinitrate (GTN; also, known as nitroglycerin) has been the most studied nitrate, used mainly in the relief of acute pain associated with angi-

na, whereas other slower release preparations, such as isosorbide mononitrate, are used for the treatment of chronic angina. The other clinically relevant NO donor in current use is sodium nitroprusside, known to provide rapid lowering of blood pressure in severe hypertensive crises (14, 15).

A great number of synthetic compounds (e.g., N-diazeniumdiolates, S-nitrosothiols, nitrosohydroxylamines and nitrosyl metal complexes) have been developed to chemically stabilize and release NO in a controlled manner, and have been exploited in many biomedical applications (3, 16). Diazeniumdiolates represent another class of NO donors to which increased attention has been paid recently for their ability to generate predictable amounts of NO (17). The biological activity of diazeniumdiolates was tested with promising results in various experimental models, such as vasospasm, pulmonary hypertension, platelet adhesion/aggregation (11, 3).

In addition, S-nitrosothiols are considered an excellent source of NO. S-nitrosothiols-based therapeutics can be considered more efficient than NO-based therapeutics, due to its more prolonged release of NO, as well as a more facile transnitrosating capability (16). These donors were proven to induce more prolonged vasodilation than the other NO donor types tested. Moreover, lipophilic S-nitrosothiols induce even longer vasodilation than the conventional S-nitrosothiols (11).

NO donors with antioxidant and hepatoprotective effects

From another point of view, there is an increase of evidence in support of the fact that NO reduces the arachidonic acid-induced oxidative stress. Also, it was demonstrated that antioxidants can prevent the l-N^G-Nitroarginine Methylester (l-NAME) potentiation of arachidonic acid toxicity. Toxic effects to mitochondria induced by arachidonic acid were demonstrated by a decline in the mitochondrial membrane potential. L-NAME potentiated this decline in mitochondrial membrane potential, this being linked to its increase in arachidonic acid-induced oxidative stress (18).

NO donors decrease the decline in mitochondrial membrane potential, due to their decrease in arachidonic acid-induced oxidative stress (19). These results indicate that NO can exert hepatoprotective effects against CYP2E1-dependent toxicity, preventing arachidonic acid-induced oxidative stress (20). Published research data sets show that NO contributes to liver homeostasis, its production playing an important role in both cytoprotectant and cytotoxicity processes (21, 22).

Experimental data shows that NO seems to be beneficial to hepatocytes, having cytoprotective effects against inflammation and tissue damage and direct cytotoxic effects on invading microorganisms and tumor cells (23, 24).

NO donors with a beneficial role in reducing inflammation and pain

Another high value therapeutic path is represented by the development of NO donor hybrid drugs. These are the new nonsteroidal anti-inflammatory NO donor drugs (NO-NSAIDS) that keep the pharmacodynamic actions of the basic compound (analgesia, inhibition of inflammation) as well as have other benefits (assigned to NO release in body) such as the protection of gastric mucosa against the irritating action of NSAIDS (25).

These compounds are prepared by adding a radical such as nitrobutyl or nitro-

sothiol by short-chain ester linkage of an NO-releasing moiety to conventional NSAIDS, such as aspirin (*NO-Aspirin*), flurbiprofen (*NO-flurbiprofen*), naproxen (*NO-naproxen*), diclofenac (*Nitrofenac*), Ibuprofen (*NO-ibuprofen*) and indomethacin (*NO-indomethacin*) (25, 26). Experimental and clinical data sets show that the capacity of NO-NSAID to release NO appears to reduce the gastrointestinal toxicity compared with NSAIDs alone (27).

The various mechanisms that underline the protective effect of NO on the stomach include vasodilation of the gastric mucosa, inhibition of caspase enzymes activity and inhibition of leukocyte adhesion (25).

CONCLUSIONS

We concluded that multiple new NO donors (such as: diazeniumdiolates, S-nitrosothiols, nonsteroidal anti-inflammatory NO donor compounds) have been developed in the last years. They were proven to have beneficial pharmacodynamics effects in various experimental models of induced vasospasm, pulmonary hypertension, inflammatory states, acute and chronic liver diseases. As we have outlined in this material, these compounds appear to be promising agents that may be used in the treatment of cardiovascular maladies, inflammatory conditions, liver function disturbances, or of neoplastic diseases.

NEWS

NEXT GENERATION SEQUENCING (NGS) AS A PROMISING TOOL IN FORENSIC GENETICS

The biggest challenge for a forensic geneticist is to obtain sufficient information from trace samples, and thus being able to sequence every DNA molecule in a sample is a very intriguing idea. At the present, the forensic markers are typed using PCR-CE and there are individual assays for autosomal STRs, Y-chromosome STRs, X-chromosome STRs, indels, mtDNA SNPs, autosomal SNPs, Y-chromosome SNPs etc. The most important advantage of NGS is that all these assays could be combined into a single NGS assay. This will save time when dealing with cases where supplementary investigations are necessary and reduce the overall time needed for processing a sample. Another advantage is that the DNA fragments do not need to be separated by lengths in CE, so all the analyzed fragments can be designed to be as short as possible, increasing the chance of typing degraded DNA (Claus Børsting, Niels Morling. Next generation sequencing and its applications in forensic genetics. *Forensic Sci Int Genet* 2015; 18: 78-89. doi: 10.1016/j.fsigen.2015.02.002).

THE HARMFULNESS OF ALCOHOL AND TOBACCO SMOKING IN CARDIOVASCULAR PATHOLOGY AND THE PERSPECTIVE OF SPIRITUAL THERAPY

Narcisa Carmen Mladin*, Maria Pușchiță
Western University "Vasile Goldiș"-Arad
*Corresponding author. E-mail: mladin_narcisa@yahoo.com

THE HARMFULNESS OF ALCOHOL AND TOBACCO SMOKING IN CARDIOVASCULAR PATHOLOGY AND THE PERSPECTIVE OF SPIRITUAL THERAPY (Abstract): A holistic approach to the human person, from a somatic, psychological and spiritual point of view, with reference to the harmfulness of alcoholism and smoking in cardiovascular pathology, highlights several therapeutic variants over time. Among them are: the current somatic therapy, which could not offer optimal solution in eradicating this vice, and psychiatry which, using will power, could not solve man's contradiction with himself, caused by a tempting and treacherous irrationality of senses, instinctive-affective desires, turned into vices, as a *"Quasi altera natura",* devoid of any bright and creative horizon. As such we propose an alternative that entails changing one's lifestyle to eliminate the harmful effect of alcoholism and smoking on cardiovascular pathology, through the perspective of spiritual therapy, accessible to contemporary society, at no cost and with no adverse events. **Keywords:** SPIRITUAL THERAPY, ALCOHOLISM, TOBACCO ADDICTION.

Tobacco smoking is a major risk factor for coronary, carotid and peripheral atherosclerotic disease; passive smoking also shows an increase in cardiovascular risk. The impact of smoking on metabolism consists of increased total cholesterol and decreased HDL cholesterol in platelet and leukocyte activation, increased circulating fibrinogen, endothelial dysfunction with the promotion of fissure in vulnerable plates, increased heart rate and blood pressure, as well as other effects aggravating myocardial ischemia due to inhaled carbon monoxide (1,2).

Smoking, together with increased blood pressure, is a strong cardiovascular risk factor; it causes cardiovascular events: stroke, myocardial infarction and peripheral vascular disease. The most effective measure to prevent cardiovascular disease is smoking cessation and lifestyle changes. In particular cases, nicotine replacement therapy might be considered. A detailed research on 36 studies comparing long-term smoking cessation rate using bupropion showed a relative success of 1.69% on control; whereas the combination of nicotine replacement therapy with varenicline yielded no results. Recently, the *Food and Drug Administration* (FDA) issued a warning regarding the safety profile of varenicline, in the sense that spreading smoke substances in the blood, across respiratory surfaces, acts on the nervous system, caus-

ing shivers, decreased appetite and decreased visual acuity. Acting on the skin, it alters its color and causes wrinkles; it harmfully influences the heart and blood vessels, increasing heart rate, creating vasoconstriction, as well as arterial hypertension. The above-mentioned show that smoking is an addiction with destructive consequences on the human being. A solution to the problem would be to detect the cause of smoking; however, so far research has not discovered a "smoking gene". Although drug therapy for smoking cessation has proven effective, its use is limited, on account of side effects and high prices; these drugs are not reimbursable in most countries, and there is a lack of information among the population on the risks smokers are exposed to. The most effective and inexpensive treatment in smoking cessation therapy is one's own will, the awareness of the harmful effects of smoking and the desire to live a healthy life (3, 4, 5).

Alcohol is regarded as the fourth risk of health problem after cardiovascular diseases. Alcohol is the most common risk factor in the occurrence and evolution of cardiovascular risk. The excessive long-term alcohol consumption increases hypertensive risk and, in parallel, the risk of strokes, or causes supra-arachnoid hemorrhage.

Physiologically speaking, alcohol passes entirely in the blood at the level of digestive surfaces; it creates irritation and necrosis in the mucous membranes, and eventually cirrhosis of the liver. Influencing the circulatory system, alcoholism creates and aggravates, like smoking, myocardial infarction, arteritis, as well as other metabolic disorders. On the nervous system it creates disturbances in reflexes, manifested paradoxically.

The alcohol can be eliminated, like smoking, through one's own will, by becoming aware of the danger it poses on health and wishing to have a healthy life, while also considering the resources wasted to the detriment of well-being. In the following lines we will attempt to present an alternative to eliminate the harmfulness of alcoholism and smoking, through the perspective of spiritual therapy (6, 7, 8).

Spiritual therapy. In principle, any desire that is inconsistent with human nature, as well as excesses of any kind, have been regarded since the oldest times as vices or enslaving passions, owing to their insatiability. In particulars, *stoics* believed that vices, which they called "*κακία"* were diseases of the soul, was mainly aimed at the spiritual part of the human person, and especially the rational factor, thought of as the divine in man. This integral, holistic, psychosomatic view, applied to ancient medical practice, becomes increasingly more topical in our times, when stress and anxiety help proliferate diseases barely heard of in the past, such as diabetes, arterial hypertension, coronary heart disease, tumors, or strokes; and smoking, drug use and alcoholism keep claiming more victims, including depression, which is triggered by specific energetic imbalance, all sorts of somatic pathologies (9, 10, 11, 12).

To reference ancient thought again, we will say that, having the main concern of continuously developing and perfecting psychosomatic human nature, it was believed that any natural thing is not bad in and of itself, but becomes bad through its defective or unnatural use, due mostly to excess (13,14). Suggestive in this sense are the words of Apuleius of Madaurus, who established that "*The first cup is for thirst, the second for mirth, the third for delight,*

the fourth for madness" (15). Hence, the need to apply moderation, after good rational *counsel;* defining the health of human nature itself by avoiding the two extremes that are harmful to it, i.e. *lack or insufficiency,* which does not satisfy necessity; and *excess* or *abuse,* which exceeds necessity. Resulting from the insatiability of lusts, alcoholism, along with other vices, generates all kind of suffering, both to the soul, by dominating it and canceling its authentic freedom of expression, and to the body, through all sorts of diseases, which ruin its health, bringing suffering, degradation and death. This is why, in order to foster health, as a normal and necessary way to develop and perfect integral (psychosomatic) human nature, education is promoted in the culture of all peoples across the world, that is**,** as a culture of the spirit, as shaping or polishing human personality according to principles intended to bring its accomplishment or perfection.

Nature comprises native predispositions, flaws and qualities, most often passed from parent to child. *Reason,* referring to learning, comprises instruction made based on arguments, to create a certain *mentality* likely to cultivate qualities and eliminate flaws contained in each person's nature. *Habits* mean practicing what was learned to create a stable attitude. Thus, habit can become a second nature (*quasi: altera natura*), when set free from the strict rule of heredity, becoming the result of environment or the imitation of new forms, freely and consciously accepted by man (15).

However, delving deeper into these three factors, essential differences were noted, both in their structure, and in their functionality. Thus, as Plato said, there are people with a *nature of gold,* willing to receive and cultivate fundamental values, summarized in: *truth, goodness* and *beauty;* but there are also coarse, difficult natures in the path towards the rational order of life. *Reason* can, in its turn, be fair, but most of the times it lacks the lucidity of a correct decision. *Habits* depend on the *power of will,* which fulfill an essential role in transforming rational decision into constant action. This leads to a contradiction between man and himself, i.e. a contradiction between vulgar pleasures, turned into habits, as blind necessities, which shut and unravel the bright horizon of life, and the light of reason or judgment of conscience, oriented towards real values intended to fulfill the aspirations of human nature, through health and authentic assertion. Thus, ancient scholars were right to deplore failure, saying: *video meliora proboque, sed deteriora sequor* (I see and approve of the better, but I follow the worse – Ovid, *Metamorphoses*, VII – 20, 21); and later, Paul the Apostle stated "*For what I want to do I do not do, but what I hate I do... I do not do the good I want to do, but the evil I do not want to do*" **(***Romans 7*, 15-19). And if this contradiction exists, it only means that human nature is suffering, as simple education as therapy of the soul, meant to find the optimal solution in its quest for accomplishment or perfection, cannot achieve everything, being most of the times destined for failure (15).

We can see that spiritual therapy as a work of divine grace brings forth in the soul the *power of faith able to convert*, to change mentalities and feelings, guiding them towards a new behavior. A concrete model in this context is given by Saint Paul the Apostle who said, referring to his own conversion: "*But whatever were gains to me I now consider loss for the sake of*

Christ ... for whose sake I have lost all things. I consider them garbage that I may gain Christ" (*Philippians 3*, 7-8). Given that excessive alcoholic drink also generates disturbances in conscience by inciting other vices, it opposes the cultivation of spiritual life, for which reason, one must nurture self-control, according to the apostolic urge, as a *virtue of moderation* and as a *norm of Christian life*: "*And be not drunk with wine, wherein is excess; but be filled with the Spirit"* (*Ephesians* 5, 18). This apostolic urge has become the *golden rule of Christian behavior*, as it was constituted as a holy tradition originating in the words of the Lord: "*And take heed to yourselves, lest at any time your hearts be overcharged with surfeiting, and drunkenness, and cares of this life, and so that day come upon you unawares."* (*Luke* 21, 34). On these grounds, Clement of Alexandria laid down in writing the appropriate manner in which Christians should use wine, as a *drink of moderation*: *"It is proper, therefore, that boys and girls should keep as much as possible away from this medicine. For it is not right to pour into the burning season of life the hottest of all liquids—wine—adding, as it were, fire to fire. For hence wild impulses and burning lusts and fiery habits are kindled [...] I however think that then especially ought reason to be introduced to mix in the feast, to act the part of director (pedagogue) to wine-drinking[...] Drink not wine to drunkenness [...] For the gurgling occasioned by the drink rushing with violence[…], is a shameful and unseemly spectacle of intemperance […].The Scythians, the Celts, the Iberians, and the Thracians, all of them warlike races, are greatly addicted to intoxication, and think that it is an honorable, happy pursuit to engage in. But we, the people of peace, feasting for lawful enjoyment, not to wantonness, drink sober cups of friendship that our friendships may be shown in a way truly appropriate to the name."* (*Pedagogues*, Book II, Chapter II, 19,2; 20,3; 25,1; 31,1) (15).

A concrete example of application of spiritual therapy, especially with regard to alcoholism, tobacco addiction and other lusts, is apparent in the action specially organized by the Transylvanian Church, after the First World War, through the work of the *missionary priest Iosif Trifa, founder of the "Army of the Lord", as movement of spiritual awakening from the death of lusts.* In the *"Foreword*" to his books, suggestively entitled according to the model of Christian hermits "*Alcohol – a spirit of the devil", Sibiu, 1936*, the following are said: "*This book is the fruit of work and concern lasting for 14 years. Around 1921, I started a movement to combat alcoholism in our people. This is a plague others have dealt with. However, unlike others, we started the fight in the name of the Lord and with the power of the Lord. We dragged our enemy alcohol where he alone cannot win: on the battlefield of the Gospel. We laid the foundations of the Great Crusade of religion against alcohol – the 'Army of the Lord' movement – and we harvested unexpected victories. The Army of the Lord now counts more than 100,000 fighters and marches victorious across the entire country. Once again it was proven that alcoholism, tobacco addiction and other lusts cannot be fought with advice and conference, but only with the power of the Gospel […] Tens of thousands of souls were delivered by this movement from the chains of devil – alcohol"* (15). Of course, faced with this success in applying spiritual therapy to combat the harmfulness of alcoholism and

smoking, we should not display an exclusivist triumph, but in reaching a common goal we ought to make a synergy of all alternatives that have proved to be efficient. Paul the Apostle urged us to this sort of sound counsel, when he said: "*Prove all things; hold fast that which is good*" (*1 Thessalonians* 5, 21) (15).

CONCLUSIONS

The tobacco smoking has an important etiologic role in cardiovascular diseases (myocardial infarct, sudden death, peripheral vasculopathies, and stroke) and pulmonary diseases (pulmonary emphysema, chronic bronchitis, lung cancer). The most dangerous factor is tobacco smoking in young age, between 20-25 years, with important medical and social consequences.

Alcoholism is defined as the alcohol dependence, characterized by a high desire to drink, the loss of control (the impossibility to stop the alcohol ingestion, despite the desire to do it), the physical dependence, with a specific clinical symptomatology and the alteration of alcohol tolerance.

The alcohol consumption, associated with familial or professional stress can represent a risk factor for cardiovascular diseases. The active association between tobacco smoking and alcohol consumption leads to the increase of cardiovascular diseases incidence, especially in a high consumption, comparatively with reasonable and medium intake.

The chronic excessive alcohol consumption is frequently associated with other cardiovascular risk factors: tobacco smoking, excessive salt and coffee consumption, hyperglycemic and hyperlipidic diet, sedentary, unhealthy lifestyle, in a familial or professional important stress.

THE INTERFERON-GAMMA RELEASE ASSAYS IN DIAGNOSIS OF TUBERCULOUS MENINGITIS

Tuberculous meningitis (TBM) occurs most often in children and is the most severe form of extra pulmonary tuberculosis with a high rate of mortality in developing countries. The diagnosis of this infection is difficult because the microscopic exam has a poor sensibility and isolation of mycobacteria in culture is time consuming. The interferon-gamma (IFN-γ) release assays are new rapid methods for the diagnosis of tuberculosis. This technic detects the level of IFN-γ produced in response to the *Mycobacterium tuberculosis* antigens using an immune enzymatic method. A recent study has evaluated usefulness of interferon-gamma combined detection in peripheral blood and cerebrospinal fluid in TBM diagnosis. The study included a group of 30 suspected cases of TBM and a control group of 39 cases of meningitis with another etiology. The detection of IFN-γ in peripheral blood and cerebrospinal fluid was realized by enzyme-linked immuno spot (ELISPOT) and enzyme-linked immunosorbent assay (ELISA), respectively. The results show that detection of IFN-γ in peripheral blood by ELISPOT had 70% sensitivity and 87% specificity in the diagnosis of TBM. ELISA for detection of IFN-γ in cerebrospinal fluid proved 83% sensitivity and 85% specificity. Also, after 4 weeks of treatment with anti-tuberculosis antibiotics, ELISA had detected a significant decrease of level of IFN-γ in patients with TBM. When the 2 methods showed positive results, the specificity for TBM diagnosis reached 100%. These findings support the usefulness of IFN-γ release assays in the diagnosis of TBM (Diya Lu, Cheng Chen, Shenglei Yu, Shu Chen. Diagnosis of Tuberculous Meningitis Using a Combination of Peripheral Blood T-SPOT.TB and Cerebrospinal Fluid Interferon-c Detection Methods. *Lab Med*. 2016;47(1):6-12).

MITOCHONDRIAL MYOPATHY: A NEW THERAPEUTIC APPROACH

MITOCHONDRIAL MYOPATHY: A NEW THERAPEUTIC APPROACH (Abstract): Restoration of deoxyribonucleic acid in mitochondrial myopathies may occur after a mechanical or chemical injury of striated muscle or by endurance training. Therapies with enzymes, gene therapies, or treatments with substances that stimulate mitochondrial biogenesis are used at the moment. Genesis of mitochondria may also come from myonuclei by releasing the nuclear respiratory factor-1/2 during muscle contractions. Multiplying of myonuclei depends on muscle satellite cell activation. Since the electromyostimulation increase the number of circulating stem cells that may participate in the genesis of new muscle fibers (adding to the deposit of specific stem cells of the muscle), and intermittent hypoxia stimulates the proliferation of muscle satellite cells, we propose to combine the two processes for the treatment of mitochondrial myopathies. Respective combined therapy may be useful for restoring damaged mitochondria by drug side effects. **Keywords:** ELECTROMYOSTIMULATION, INTERMITTENT HYPOXIA, MITOCHONDRIAL MYOPATHIES

The syndrome comprising mitochondrial myopathy, encephalopathy and lactic acidosis have genetic causes, being inherited through maternal line. Restoring muscle mitochondrial deoxyribonucleic acid (DNA) may be the consequence of the healing process after producing a chemical or mechanical lesion of striated muscle (1, 2). In patients with mitochondrial myopathies, endurance training based on concentric exercises stimulate the transformation of stem cells into new muscle fibers with mitochondrial DNA restoration (3). A subsequent study found that 12 weeks of endurance exercises for the lower limbs in patients with the same condition resulted in an increase in aerobic capacity, mitochondrial activity and number of muscle cells satellites, but not in a significant restoration of mitochondrial DNA (4). One case study showed how the force exercises have reduced the rate of a sporadic transfer ribonucleic acid (tRNA) point mutations at an adult with mitochondrial myopathy, but that work has not been evaluated the muscle performance nor the satellite muscle cells characteristics (3). The current therapeutic strategies for mitochondrial myopathies are based on therapies with enzymes, gene therapies, nucleoside therapies, and also on the stimulation of mitochondrial biogenesis by the administration of resvera-

trol, 5-aminoimidazo-4-carboxamide ribonucleotide, nicotinamide riboside, or even antioxidants (5). In this paper we propose a new therapeutic strategy, based on the assessment of relations between the biogenesis of mitochondria and muscle stem cells.

ELECTROMYOSTIMULATION COMBINED WITH INTERMITTENT HYPOXIA - POTENTIAL METHOD TO RESTORE MUSCULAR MITOCHONDRIA HYPOTESIS

The decrease in intramuscular ratio of adenosine triphosphate/adenosine diphosphate (ATP/ADP) and of phosphocreatine concentration activates adenosine monophosphate-activated protein kinase (AMPK), which promotes mitochondrial biogenesis by peroxisome proliferator-activated receptor-gamma coactivator-1 (PGC-1) and nuclear transcription factors (NRFs) (6, 7). Subsequently it was established that a factor arising from myonuclei (nuclear respiratory factor-1/2 - NRF-1/2) that stimulate mitochondrial biogenesis is released due to physical exercise (8).

Given that muscular stem cells can generate myonuclei or differentiate into new muscle cells (9} it follows that in both modes have an indirect contribution to mitochondria biogenesis. In vivo activation of satellite stem cells is made by nitric oxide (NO) released during exercise (10). In support of this mechanism it comes that at a young age, muscular stem cells activation is made by muscular attrition (11). Practically after only 4 weeks of endurance exercise the number of mitochondria in muscle fibers almost doubled (12). Electromyostimulation (EMS) made with frequency between 50 and 2,000 Hz performed on human subjects for 21 days has led to an increase in number of myonuclei in muscular fibers and possibly to hyperplasia of striated muscle, process assumed to be induced by proliferation of muscle cell satellites (13). Correlating this fact with the above observations strengthen the hypothesis that electromyostimulation activates satellite stem cells and implicit mitochondrial biogenesis. Intermittent hypoxia combined with surface electromyostimulation cause circulating stem cell proliferation (14), which can add to satellite cells during the formation of new muscle cells (13). Moreover, hypoxia activates Notch signals with role in muscular satellite cell proliferation, the same action having the stimulation of Wnt/B-catenin pathway (15).

It seems that mutant mitochondrial DNA in muscle satellite cells is lost if their replication to form new muscle fibers occurs rapidly, creating new prospects for treating mitochondrial myopathies (16). Given the supposed effects of intermittent hypoxia combined with electromyostimulation on muscle stem cell activation and implicitly on mitochondrial biogenesis, this therapy could be indicated for myopathy caused by mitochondrial defects.

DISCUSSION

An indirect argument for the fact that electromyostimulation induce biogenesis of mitochondria is that six weeks of low frequency EMS (10 Hz) had the effect of increasing muscle volume and degree of pinnate, lower blood pressure and increase aerobic capacity (i.e. the number of mitochondria of muscle) (17). In addition to the combination with intermittent hypoxia, EMS can be combined with modern therapies of mitochondrial myopathies, and in

particular with the use of riboside-nicotinamide (compound believed to increase the intracellular synthesis of nicotinamide adenine dinucleotide - NAD+) (18) and therefore the efficiency of communication between the nucleus and mitochondria (19).

The combination electromyostimulation - intermittent hypoxia could be used to control quality and/or quality defects of mitochondria appeared as unwanted side effects of some drug therapies: analgesics and anti-inflammatory (aspirin, acetaminophen, naproxen), anesthetics (bupivacaine lidocaine, propofol) antiarrhythmics (amiodarone), antianginal (perhexiline, Dethylaminoethoxyhexesterol), antibiotics (tetracycline), antiepileptics (valproic acid), antidepressants (amitriptyline, amoxapine, citalopram, fluoxetine), antipsychotic agents (chlorpromazine, fluphenazine, haloperidol, risperidone, quetiapine, clozapine, olanzapine), anxiolytics (alprazolam, diazepam), barbiturates (amobarbital, aprobarbital, butabarbital, butalbital, methylphenobarbital, pentobarbital, phenobarbital, primidone, propofol, secobarbital, thiobarbital), cholesterol medications (statins - atorvastatin, fluvastatin, lovastatin, pitavastatin, pravastatin, rosuvastatin, simvastatin, bile acids - cholestyramine, clofibrate, ciprofibrate, colestipol, colesevelam), diabetes medication (metformin, troglitazone, rosiglitazone, buformin), chemotherapy (mitomycin C, profiromycin, adriamycin), anti-parkinsonian (tolcapone), lithium, disulfiram, medication anti HIV (abacavir sulphates, Hivid (ddC, zalcitabine), zidovudine, ddI, didanosine, d4T, stavudine) (20).

CONCLUSIONS

In our study, based on proven functional relationships between mitochondrial biogenesis and muscle stem cells, we propose the combination electromyostimulation-intermittent hypoxia to be used as mitochondrial myopathies treatment, possibly in association with gene therapy or administration of substances that stimulate mitochondrial biogenesis.

Electromyostimulation combined with intermittent hypoxia may potentially be used for the repair of mitochondrial damage caused by various drugs.

EVOLUTION OF SYNCHRONOUS BILATERAL BREAST CARCINOMA IN A YOUNG PATIENT

Elena Manea[1*], Anca Munteanu[1,2]

1. Radiotherapy Department, Regional Institute of Oncology Iasi, Romania
2. University of Medicine and Pharmacy "Grigore T. Popa ", Iasi, Faculty of Medicine, Romania
*Corresponding author. Email: dr.elenamanea@yahoo.com

EVOLUTION OF SYNCHRONOUS BILATERAL BREAST CARCINOMA IN A YOUNG PATIENT (Abstract) Bilateral breast cancer incidence is appreciated to be between 0.3 to 12% and is determined either by a hereditary load associated with chromosomal instability under the effect of environmental factors, or by the evolution in a particular hormonal context which gives biological aggressiveness. We present the case of a patient, aged 38 years, clinically, imagistic and bioptic diagnosed with left axillary lymph node metastases of breast carcinoma NST invasive G3, IHC - RE = 60%, RP = 30%, HER2neu = 2 +, Ki67 = 20% , in August 2013. Patient followed neoadjuvant chemotherapy treatment during September-October 2013. In December 2013 she was clinically and imaging diagnosed with bilateral breast cancer, for which surgical intervention was done which consisted of bilateral radical Madden mastectomy with bilateral axillary lymphadenectomy. BAP - invasive carcinoma NST: left breast - pT2mN3a G2, right breast - pT3mN3a G2, IHC - RE = 90%, RP = 70% HER2neu = 2 +, Ki67 = 50%. During the period of January-March 2014, the patient followed adjuvant chemotherapy and Herceptin. Bilateral breast ultrasound assessment in April 2014 revealed: left axilla - liquid blade 29 / 6mm; right axilla - oval ganglion 9 / 5mm. Abdominal and pelvic ultrasound: empty uterine cavity, bosselated contour; at left ovary level multiple cystic formations. During the period of May-June 2014, adjuvant radiation therapy and ovarian irradiationwas administered to the patient. Subsequently hormone therapy was initiated. Following CHT / ovarian irradiation patient continues to experience intermittent uterine bleeding, which is why a total hysterectomy with bilateral ovariectomy was done, and BAP: cervical, endometrialand left ovary with tumor multifocal infiltration with histopathological aspect of invasive breast carcinoma NST. Periodic imaging evaluations do not reveal local or distant recurrence. The particularity of this case is synchronous bilateral breast cancer diagnosis in a young patient complicated in its evolution by ovarian metastases. This form of metastasis is rare in young women and occurs in advanced stages of the disease. **Keywords**: SYNCHRONOUS BILATERAL BREAST CARCINOMA, MULTIMODAL TREATMENT, OVARIAN METASTASES.

Breast cancer is the most common type of cancer among women with increased incidence due to screening, resulting in improved prognosis and survival [1, 2]. In breast neoplasm, clinical forms and biological characteristics are very diverse. Of all breast cancers, BBC (bilateral breast cancer) is 2-6% [1]. Bilateral breast cancer incidence is appreciated to be between 0.3 to 12%. In breast cancer the most common

secondary dissemination are of the bone, liver, lung and brain, but may be metastatic sites other organs such as the peritoneum, ovaries and teguments.

MATERIAL AND METHOD:

In this paper we present the case of a patient, aged 38 years, clinically, imagistic and bioptic diagnosed with left axillary lymph node metastases of mammary gland carcinoma NST invasive G3, IHC (immunohistochemistry) ER (estrogen receptor) = 60%, PR (progesterone receptor) = 30%, Her 2neu = 2 +, Ki67 = 20%, in August 2013.Neoadjuvant chemotherapy followed during September-October 2013, 3 CAF protocol cycles (cyclophosphamide 800mg, doxorubicin80mg, 5-FU 800mg).

In December 2013, a bilateral breast ultrasound detected in the right breast a nodular formation of about 1.5 - 2cm, while on the left breast endured placard and bilateral axillary infracentrimetricaladenopathy.

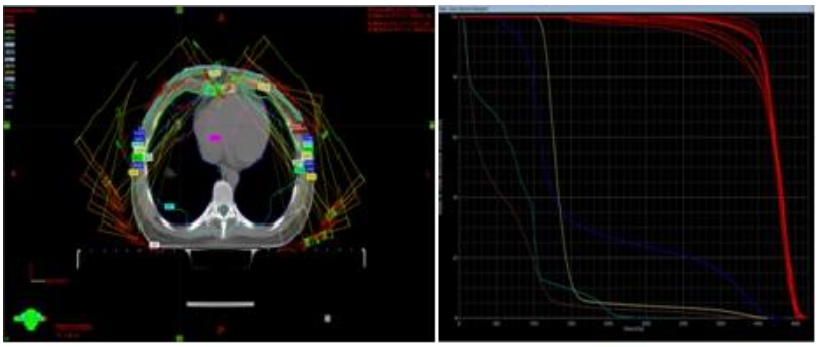
A pelvic ultrasound from December 2013 detects a heterogeneous consistence uterus, 45/36 / 72mm with two fibroid nodules 19 / 15.5mm and 12 / 15mm with 5.7mm endometrium, left ovary 40 / 24mm positioned retrouterin, normal consistency, right ovary 32 / 17mm normal echostructure and empty Douglas space.

A bilateral radical mastectomy type Madden with axillary bilateral lymphadenectomy with BAP (ID pathological) - NST invasive carcinoma: left breast - pT2mN3a G2, 11 excised lymph node metastasis; right breast - pT3mN3a G2, 15 lymph node metastasis in 19 excised IHC- RE = 90%, RP = 70%, Her 2neu = 2 +, Ki67 = 50% , FISH: HER2neu amplified.During the time period January-March 2014, the patient followed adjuvant chemotherapy: 1 CAF protocol cycle, 4 series of chemotherapy with Paclitaxel 300mg and initiated therapy with 300mg of Herceptin.

In April 2014, imaging evaluation through bilateral breast ultrasound revealed: left axillary - liquid blade 29 / 6mm; right axillary - oval ganglion 9 / 5mm. Abdominal and pelvic ultrasound: empty uterine cavity, bosselated contour; at left ovary level multiple cystic formations.

During May-June 2014 was administered to the patient adjuvant radiotherapy at ACC ClinaciX10, photons E = 10MV, DT = 42.56Gy/16fr/2.66Gy/fr/ chest wall bilaterally and axillary lymph nodes areas, bilateral supraclavicular region and right lateralcervical (Fig.1, Fig.2) and ovarian irradiationat Clinac accelerator 2100sc, with photons E = 10MV, DT = 12Gy/4fr/3Gy /fr.Subsequently adjuvant hormone therapy was initiated with Tamoxifen.

Fig. 1. Treatment plan: a- target volumes delineation; a, b – patient in simulation position



a b

Fig. 2 Treatment plan: a- radiation fields; b- dose-volume histogram evaluation

In the context of abdominal and pelvic ultrasound appearance and persistent uterine bleeding even after ovarian suppression by chemotherapy and radiation therapy, total hysterectomy with bilateral ovariectomy was performed. BAP: cervical, endometrial and left ovary with tumor multifocal infiltration with histopathological aspect of invasive breast carcinoma NST.

Thorax CT (computer tomography) in September 2015 - without signs of local or distant recurrence, persistence of microadenopathies of ~ 9 / 10mm right hilar. In upper abdominal sections a simple hepatic cyst was identified in the segment IVb of ~ 4.5mm.

Pelvis MRI (magnetic resonance imaging) in November 2015 – total hysterectomywith bilateralovariectomy without pathological contrast intake – stationery aspect, absence pelvic adenopathies.

DISCUSSION:

The risk of developing BBC is two to six times higher in women with history of unilateral breast cancer [2, 3].

BBC can be classified into subcategories, synchronous and metachronous. This classification is based on the time interval between diagnosis of primary tumor in the first breast and the second breast. Some previous studies have defined the synchronous bilateral breast cancer (SBBC) as the development of breast cancer in the time interval of 0- 12 months [4].

According to the WHO guidelines in 2012, BBC is defined as SBBC when contralateral breast carcinoma is diagnosed within three months [1].

SBBC is defined in some studies, from a epidemiological point of view, as the development of breast cancer within 12 months [5,6]. The SBBC incidence is relatively low, between 1 and 3% of all breast cancers. SBBC and MBBC have different biological characteristics, reflected in the histopathological characteristics, stage and prognosis [7].

The appearance of the second contralateral breast tumors can be synchronous (in less than 6 months after the first primary tumor in the first breast) or metachronous (after 6 months of diagnosis of the primary tumor in the first breast) [8].

In the presented patient case, the contralateral breast cancer was diagnosed 5 months after the left breast cancer diagnosis and was considered synchronous, ac-

cording to the interval of less than 6 months.

Some studies have indicated a worse prognosis and low survival rate for BBC. Conversely, other studies have claimed that there is no significant difference in the survival rate between UBC and BBC. Despite previous and ongoing studies, the prognosis and survival of patients with BBC remain uncertain [1].

Synchronicity and metachronicity are usually associated with local recurrence, hematologic and lymphatic spread to the lungs, bones and liver.

Early detection of contralateral breast cancer is of the most importance, emphasizing the importance of breast self-examination [9]. The standard for breast cancer screening is the mammography, some authors recommend breast MRI scan, which is more sensitive in comparison to mammography, but the high cost and lack of availability is limiting as a screening indication. There are no clear treatment guidelines for bilateral breast cancer. Patients are often treated with bilateral mastectomy, conservative surgery has an unclear importance [9].

In our case, multimodal treatment was administered according to the stage, histological and prognostic factors individually for each of the tumors.

Studies suggest that there is no significant difference in survival rate for patients with MBBC compared with those with SBBC. Synchronous tumors were associated with decreased survival in comparison to metachronous tumors [10].

Most often, patients with BBC are receiving radical surgery based on the idea that these tumors are biologically aggressive. However, scientific evidence to support this are split. Conservative treatment for BBC may be feasible also in the case of unilateral breast cancer [11].

BBC is more common in young aged women and most of these tumors are estrogen dependent. There is a concordance between the primary tumor and contralateral breast cancer from a histological point of view, of the receptors ER, PR and HER2. Some studies argue that there is no clear relationship between positive ER and PR and tumor bilateral localization. It seems that the BBC incidence is higher in cases with the overexpression HER-2 [2].

BC can metastasize to the bone, liver, lung and brain, but can affect other organs such as the peritoneum, ovaries and tegument.

Metastatic ovarian tumors, that are called Krukenberg tumors, occur frequently after the age of 40 years [12]. The appearance of these tumors at a young age is very rare and represents approximately 2% of all cases. The occurrence of ovarian metastases in breast cancer represents an advanced stage of the disease [13].

It seems that patients with Krukenberg tumors with BC as a starting point, unlike other tumor locations, have a good prognosis [13]. Surgery is the optimal treatment for these tumors, as it has been practiced in this case.

CONCLUSIONS:

The particularity of this case is synchronous bilateral breast cancer diagnosis in a young patient complicated in its evolution with ovarian metastases. This form of metastasize is rare in young women and occurs in the advanced stages of the disease. The prognosis for this patient is reserved considering the age under 40 years, synchronous neoplasia, nodal status (pN3a bilateral), the advanced stage (IIIC),Her

2neu positive status.

In the case of synchronous bilateral breast carcinoma there should be applied adequate multidisciplinary management and rigorous supervision of patient to improve survival and quality of life.

DEVELOPMENT AND VALIDATION OF THE HIGH PERFORMANCE LIQUID CHROMATOGRAPHY METHOD FOR THE QUANTITATIVE DETERMINATION OF ERYTHROMYCIN IN DERMO-PREPARATIONS (Abstract): **Purpose**: For the analysis of erythromycin (ER) in topical pharmaceutical forms we developed a high performance liquid chromatography dosage method (HPLC) greatly improved over the method formalized by the European Pharmacopoeia 5th ed. **Materials and methods:** The work conditions for using a chromatography column with C18 stationary phase were established as follows: optimal column temperature, 45 ° C; the mobile phase consisted of a mixture of 0.001 M disodium phosphate solution : acetonitrile in the ratio 20:80, volume of sample injected 20 µL, injection rate 1 mL/min and spectrum was recorded at λ = 200 nm. The method was validated by determining the following parameters: system precision, linearity, limit of detection (LOD), limit of quantification (LOQ) and accuracy. **Results:** We determined linearity in the concentration range studied, 0.025 to 1.5 mg/mL. The equation of the regression line is: A = 53.7430 · C + 0.00203 with a regression coefficient of 0.9997. The method has LOQ = 0.0196 mg / mL and LOD = 0.005969. The accuracy of the method is appropriate, the ER recovery degree is in the range of 101.27 - 104.99%. **Conclusions:** The HPLC method with UV detection for the quantitative determination of ER is manageable, responsive, linear, precise and accurate and it can be used for the quantitative analysis of ER in topical pharmaceutical formulations. **Keywords:** ERYTHROMYCIN, LIQUID CHROMATOGRAPHY, UV DETECTION.

The European pharmacopoeia 5th ed. formalizes a method for the quantitative determination of erythromycin by high performance liquid chromatography (HPLC) which has two major drawbacks: the stationary phase is the styrene-divinylbenzene copolymer, and column temperature is 70 °C (1, 2). The objective of this study was to develop and validate a highly selective method for the identification and quantitative determination of erythromicin in dermo-preparations.

MATERIALS AND METHODS

Materials: Acetonitrile (ACN) and chromatographic grade disodium phosphate (Merck, Germany). ER reference substance, purity 99.70% (Sigma-Aldrich, USA). Erythromicin (ER) purity 99.85% (Zhejlang Pharmaceutical Co. Ltd. China Sanmen Hengkang); doubly distilled water, conductivity 0.01 μS/cm. *Solutions: K_2HPO_4 0,001M solution;* the *standard solution* was prepared by dissolving 50 mg ER (reference substance) in the mobile phase in a 5 mL volumetric flask, the *stock solution* is obtained by diluting a determined volume of the stock solution with the mobile phase in a volumetric flask in order to prepare solutions of concentrations of 0.025 - 1.5 mg/mL.

Methods: *Chromatographic conditions:* Thermo Fisher Scientific Ultimate 3000 Liquid Chromatograph, equipped with UV-VIS with Diode Array Detector. The method is based on the use of a chromatography column type Teknochroma Tracer Excel 120 OSDB C18, 150 mm x 4.6 mm, particle size 5 μm. Column temperature was maintained at 45 °C. The mobile phase was a mixture of 0.001 M disodium hydrogen phosphate : acetonitrile solution in the ratio 20:80. A volume of 20 μL was injected at a rate of 1 mL/min and the spectrum was registered at λ = 200 nm. *Optimization of the chromatographic conditions* - ER retention time optimization was achieved by changing the ratio of the two components of the mobile phase and of work temperature. *System accuracy (repeatability):* an ER solution with a concentration of 0.5 mg/mL was prepared. A volume of 20 μL of each solution was injected 10 times in succession in the chromatographic system and the peak areas and the retention time were registered for each solution. The mean value, standard deviation (SD) and relative standard deviation (RSD) were determined. *Linearity:* We investigated ER response linearity in a range of 5% of the reported ICH value and 300% of the concentration of interest of 0.5 mg/mL (3). In those circumstances, linearity was studied in the range of 0.025 - 1.5 mg/mL ER. We plotted the calibration curve and mathematical data were processed by linear regression ($R^2 \geq 0.990$). *The limit of detection (LOD) and the limit of quantification (LOQ):* we considered three points close to the reporting threshold and calculated the regression coefficient for the linear model in order to assess the considered trend. From the calculation of the intercept and of the residual standard deviation of the intercept, we estimated the limits of quantification and detection according to the formulas below

$$LOQ = \frac{10 \times \sigma}{b} \qquad (1)$$

$$LOD = \frac{3{,}3 \times \sigma}{b} \qquad (2)$$

Wherein σ - residual relative standard deviation, b - slope calculated for the range in question.

Accuracy was estimated by determining the recovery rate, using three solutions of three concentrations ranging between 0.1 - 1 mg/mL. Concentration was calculated using the calibration line and the values obtained were compared according to the experimental concentrations.

RESULTS AND DISCUSSION

Wavelength for ER was established on the basis of the maximum absorption in the recorded UV spectrum (fig. 1).

In order to optimize retention times, we used ACN with a ratio of up to 85% and found that introducing different ratios of ACN : 0,001M K_2HPO_4 solution produces a

different pattern of signals retrieved for ER. It was not possible to use a temperature over 55 °C, because the maximum column temperature is 60 °C. The use of a temperature of 45 °C efficasized separation, the number of theoretical trays and signal height having their highest values (tab. I, fig. 2).

ER peak area shows a RSD = 1.785 and retention time a RSD = 1.023. These values demonstrate that the system is compatible (tab. II, fig. 3).

We notice a linear variation of the peak area depending on sample concentration (fig. 4).

RSD	1.78467			1.0231		

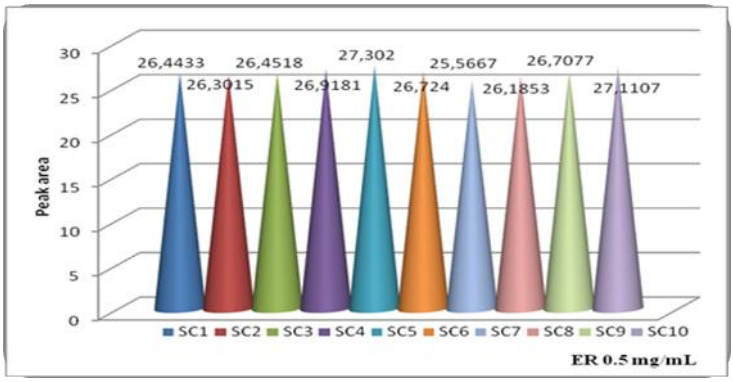

Fig. 3. Peak individual area

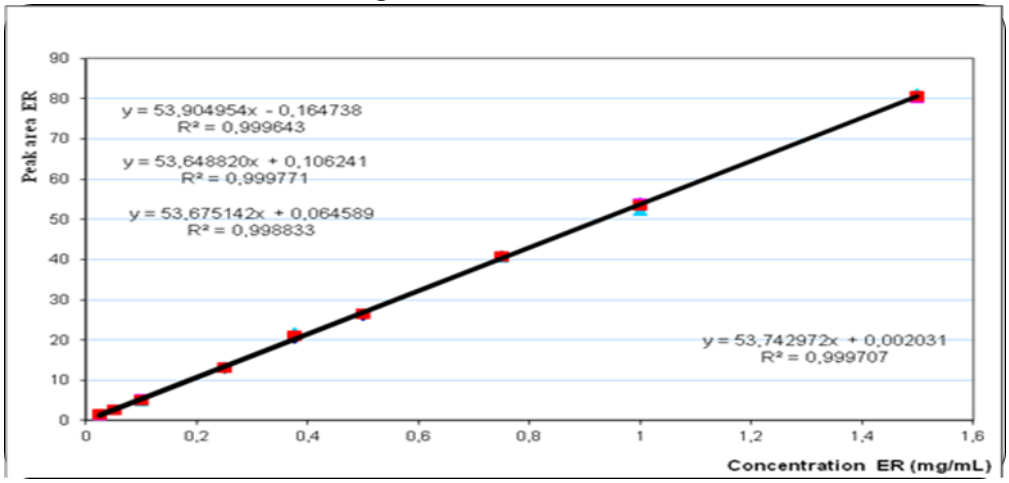

Fig. 4. Calibration line for ER determination under the chromatography conditions described

The results show that the method has LOQ = 0.0196 mg/mL and LOD = 0.005969 mg/mL (RSD = 0.0955). These values support the use of the method of ER determination at concentrations used in topical and even in internal medications. For each concentration level, we obtained a recovery rate in the range of 101-104% appropriate to validate the accuracy of the method (tab. III) (4 -8).

CONCLUSIONS

In this paper we presented data obtained in the development of a reliable method for the quantitative determination of ER by HPLC with UV detection. The method was validated by the determination of several specific validation parameters. Thus, linearity was measured in the studied concentration range of 0.025 - 1.5 mg / mL. The regression line equation is:

$A = 53.7430 \cdot C + 0.00203$ with a regression coefficient of 0.9997. The method has LOQ = 0.0196 mg/mL and LOD = 0.005969. The accuracy of the method is appropriate and the recovery rate of ER is in the range of 101.27 - 104.99%. The new HPLC method with UV detection we developed and validated for the quantitative determination of ER is manageable, responsive, linear, precise and accurate and can be used for the quantitative analysis of ER in topical formulations.

NEWS

NOI SUBSTANȚE MEDICAMENTOASE CU ACȚIUNE ANTIDIABETICĂ - EMPAGLIFLOZIN

Empagliflozin face parte din clasa medicamentelor antidiabetice noi, care determină glicozurie prin blocarea recaptării glucozei în tubul proximal. Pierderea a 50-100 g de glucoză / 24 de ore prin urină determină reducerea glicemiei *à jeun*, dar mai ales a glicemiei postprandiale, un consum crescut de energie cu 200-400 kcal / zi şi scăderea tensiunii arteriale. Eficacitatea tratamentului nu scade în timp, deoarece nu depinde de propria producție de insulină. S-au efectuat studii care evaluează siguranța tratamentului cu empagliflozin care va apărea în curând în portofoliul de antidiabetice în Republica Cehă. Aceste studii au demonstrat eficacitate mare, siguranță şi tolerabilitate bună pentru empagliflozin. Totodată, a fost descrisă o incidență mai mare a infecțiilor genitale non-severe, în special la femei. Medicamentul nu produce hipoglicemie. În combinație cu sulfoniluree, hipoglicemia poate să apară. Empagliflozin nu provoacă deshidratare semnificativă clinic sau hipotensiune arterială la pacienții cu vârsta de aproximativ 60 de ani, dar se recomandă precauție în tratamentul cu empagliflozin la pacienții vârstnici. Empagliflozinul prezintă avantajul interacțiunilor clinic nesemnificative cu alte medicamente şi posologia simplă de 1 comprimat / zi, administrat oral. În concluzie, empagliflozin este agent antidiabetic oral eficient cu un potențial de aplicare pe scară largă în toate etapele de diabet zaharat de tip 2, în monoterapie sau în combinație cu alte medicamente. Tratamentul este asociat cu pierderea in greutate şi cu scăderea tensiunii arteriale. Apariția efectelor secundare este rară, cu excepția incidenței crescute a infecțiilor genitale în special la femei şi risc crescut de hipoglicemie atunci când empagliflozin este combinat cu antidiabetice de tip sulfoniluree. INFLAMMATORY BOWEL DISEASES AND AIR POLLUTION (Abstract). Air pollution is responsible for the increase in mortality, morbidity and a high number of hospitalizations for respiratory and cardio-vascular diseases. Recently, several studies have shown that air pollution can also affect the digestive system. The major impact was observed on inflammatory bowel diseases (Crohn's disease and ulcerative colitis).Air pollutants that have the great impact on the digestive system health are: gases, especially ozone, particulate matter and heavy metals like lead, cadmium. **Material and Methods**: Forty-six articles and one book were evaluated for the purpose of this study. The articles are indexed in international databases, including PubMed, PMC, Scholar Google, and MEDLINE. **Results**: We present here the current understanding of the mechanisms by which air pollution can affect intestinal tissues. There are three mechanisms that can be taken into consideration: the direct effect of pollutants on epithelial cells; the alteration of the immune response and the influence of air pollution on the intestinal microbiota. The gene – environment relationship was also discussed in the case of the inflammatory bowel diseases. **Conclusions**: Up to this moment there are several indicators which show that pollution can have a negative impact on the intestinal tract, but the evidence is limited. The current studies have many limitations and confusion factors that must be measured and corrected so that the specific factors can be correctly evaluated for intestinal diseases. Studies on animals must verify the biologic plausibility of obtained data. **Keywords:** INFLAMMATORY BOWEL DISEASES, AIR POLLUTION, CYTOKINES, MUCOSAL INFLAMMATION, GUT MICROBIOTA, GENE-ENVIRONMENT RELATION.

The concept of air pollution refers to the presence of substances in air that can have a negative effect on human health.

The most famous incident related to the effect of acute air pollution on human health is the toxic fog accident in London in 1952. There were two previous episodes where air pollutants have determined increased mortality and morbidity: in 1928, in the Meuse Valley and in 1948 in Donora. The sources that have released pollutants in these areas were mostly stationary sources represented by industrial facilities. It was the meteorological conditions that have led to the increase in mortality and morbidity due to the phenomena of thermic inversion. Several studies have proved that long-term exposure to pollutants can reduce average lifespan by a few years and increase mortality. Thus, the APHEIS and APHEA study (1, 2), which investigated the impact of air pollution with particles and other air pollutants in Europe has demonstrated that, in Bucharest, the age standardized mortality rates (per 100,000 people) will be equal to 1127 if the level of air pollution with PM_{10} (particulate matter)

is in a range 14 –73 μg/m^3. If the air pollution level will drop by 5 μg/m^3, between 3,300 to 7,700 early deaths annually will be prevented, 500 to 1000 of which are associated with short term exposure (1). After the acute episodes of pollution mentioned above, legislative measures have been adopted, which have considerably lowered air pollution levels. A study conducted in U.S.A. assessed the changes registered in the life expectancy in relation with the levels of air pollution with fine particulate in the period between 1980 and 1990. The result of the study showed that, when the level of pollution with fine particle was lower than 10 μg/m ^{3}, there was an increase in the mean of life expectancy of 0.61±0.20 year (p=0.004) (3).

OBJECTIVE

This article tries to find connections between air pollution and the potential effects on human health especially between air pollution and intestinal diseases, especially inflammatory bowel diseases.

MATERIAL AND METHODS

Forty-seven articles and one book were evaluated. The articles are indexed in international databases, including PubMed, PMC, Scholar Google, and MEDLINE.

Effects of air pollution on human health

Studies have shown an increase in morbidity, number of hospitalizations and mortality during and immediately after an episode of acute air pollution.

a) Increased levels of air pollution can have impact on respiratory system with decreased ventilatory function in healthy individuals, modified ventilatory performance in exposed children, worsening of respiratory symptoms in pulmonary diseases like chronic obstructive pulmonary disease and acute attacks of asthma.

b) Also, recent studies have proven a consistent relation between air pollution with particles and cardio-vascular pathology. Exposure to an increased level of particles in ambient air can determine an increased rate of mortality by rhythm abnormalities and coagulation modifications, increasing the chance of myocardial infarction and stroke (4).

c) Another type of pathology that can be induced by air pollutants is significant intestinal pathology. There are very few studies in this regard.

The influence of air pollutants on intestines

In case of air pollutants exposure, the substances that enter the organism by inhalation are mostly eliminated. The main elimination path of particles and gases dissolved in mucus is done using the mucociliary system. By using the mucocilary escalator, the pollutants are taken towards the buccal cavity, where they are coughed or swallowed. By swallowing, the air pollutants can rapidly reach the intestines. Gaseous pollutants and particles can induce systemic inflammation that can have significant impact on intestines.

Pollutants that can induce intestinal pathology

Regarding the evaluation of the impact of environmental pollutants on digestive diseases, a relatively small number of studies have been done.

Pollutants that can induce intestinal pathology include:

- Gaseous pollutants like ozone, sulfur dioxide, nitrogen oxides and nitrogen diox-

ide in particular, carbon monoxide and carbon dioxide,

- Volatile organic substances like benzene,
- Particles. These represent a mix of biological elements like bacteria, fungi, pollen as well as particles with a high absorbent capacity for different gases like polycyclic aromatic hydrocarbons like benzo(a)pyrene. The particle composition can also have nitrates, sulfates, organic carbon or metals like lead, cadmium, etc. The particle structure depends on the source that releases the pollutants in the air.

The pollutants sources can be either fixed or mobile. The pollutants can result from the burning of fossil fuels in industry, for thermal energy, from the combustion of biomass or from traffic.

Of all air pollutants, it appears that ozone and particles have the greatest impact on intestinal pathology. It was determined that exposure to ozone can induce inflammation in both humans and animals, which will cause an increased cellular permeability and the destruction of mucosal barrier integrity (5). Important effects have, also, been identified for particles, as presented earlier. Regarding the exposure to nitrogen oxides, important intestinal effects have been identified, both in humans and animals, in case of exposure to very high concentrations.

The relation between air pollution, smoking and intestinal inflammatory diseases

Air pollution with particulates matter can appear due to several type of sources like burning fossil fuel for heating and smoking, especially in indoor spaces. Smoking can influence the group of intestinal bowel diseases. Smoking is associated with Crohn's disease, having a negative impact on the evolution of the disease (6, 7). Ulcerative colitis is more frequent in nonsmokers or previous smokers and the evolution of the disease is positively influenced by smoking (8).

Mechanisms by which air pollution can affect intestinal tissues

Multiple mechanisms can be taken into consideration, which could explain the impact of air pollution on bowels. Because there are few elements that evaluate the effect of air pollution on bowels, the proposed mechanisms for analysis are extrapolated starting from research on other organs and systems like the respiratory and cardiovascular systems.

a. The direct effect of air pollutants on epithelial cells

The direct effect of pollutants on epithelial cells could be considered. There is aggression, especially of particulate matter, against epithelial cells of the respiratory system. Modifications were found in exposed individuals that have pre-existing lesions as well as healthy individuals. These modifications have been seen on animal experiments as well as *in vitro* studies (9-13). A study done by Manzo *et al.* has demonstrated that in case of exposure of healthy cells, from the tracheal pathways or at the alveolar levels to diesel type air particles, have not registered a notable effect. However, if the pulmonary epithelial cells are already in a state of inflammation through the action of exogenous cytokines, like TNF-α (tumor necrosis factor α), IL-1β (interleukin 1β), and IFN-γ (interferon γ), due to previous exposure to diesel particles, they become incapable of responding to the increased level of oxidative stress, which will cause injury and dysfunc-

tion of the epithelial barrier and increased permeability (14). The action of environmental pollutants like diesel particles will, thus, have a greater effect on individuals with genetic predispositions and other conditions that induce inflammatory afflictions like Inflamatory Bowel Diseases (IBDs) (14).

Another study has evaluated the effect of administering a single oral dose of diesel particles on rats and has observed DNA injuries in colonic epithelial cells (15).

The effect on epithelial cells caused by exposure to air pollutants is the same, regardless of the exposed zone, respiratory or digestive. Epithelial cells generate radical oxygen species (ROS) as a response to exposure to particulate matter from air, inducing epithelial barrier disruption and increasing gut permeability (16).

b.The alteration of the immune response

In both Crohn's disease and ulcerative colitis, there is a modified and over reactive immune response (17). Air pollution has an immunomodulation effect, of inducing systemic inflammation, which causes an increased risk for autoimmune diseases and related diseases like type 1 diabetes, neuro inflammation or increased cardiovascular risk by systemic inflammation. This means it has a significant effect on inflammatory bowel diseases as well (18-21). Many of these effects are associated with urban development and industrialization, which would be favorable elements in the hygiene hypothesis of inflammatory bowel disease (22). This hypothesis suggests that persons with a decreased exposure to infections developed in childhood and at more precarious hygienic conditions in adulthood can have a deficit of „friendly" microorganisms or elements that stimulate the development of T regulatory cells, or they do not develop sufficient immune mechanisms due to the fact that they did not encounter harmful microorganisms. Individuals in this category have a higher incidence in chronic immune diseases, including inflammatory bowel diseases.

Zanobetti *et al.* (2009) and Ritz (2010) have shown that, at least in part, autoimmune diseases can be explained by the effect of air pollutants (23, 24).

The mechanisms used could be systemic oxidative stress, the stimulation of hematogenic medulla, the increase in the cytokine levels in blood and the increase in number of white blood cells The effect demonstrated *in vitro* (9, 25-33) of cellular immune activation could support this theory (34, 35). For example, IL-6 and TNF-α produced by peritoneal macrophages in mice are induced by the exposure to particles (both fine particles and large diameter particles). TLR2 (toll-like receptor 2) and TLT4 appear to mediate differently the response to air pollution. However, the exposure of alveolar macrophages in humans to particles in the urban air and diesel type particles induce a suppression of TNF-α and secretion of IL-6 and IL-8 (36).

Another study, performed in Seoul, has shown a dose dependence of the pro-inflamatory level of cytokines (IL-1, TNF-α, and IL-6), the type of cytokines Th0 (IL-2) and the type of cytokine Th1 (IL-12 and IFN-γ) in exposure to particles with the diameter of 2.5 μm. The activity of the oxidative stress related genes, like HSP 1a (heat shock protein 1a), HSP 8 (heat shock protein 8) and SOD (superoxide dismutase), and tissular lesions related genes, like MMP 15-19 (matrix metaloproteinases 15 and 19) and SLPI (secretory leukocyte peptidase inhibitor) were also influenced, dependent on exposure time

(37).

PM 2.5 can also induce an increase in the distribution of T cells in lymphocytes and a decrease of the CD4+/CD8+ ratio. Based on these result the authors of the Soul study suggest that the pollution of air with PM 2.5 can induce a Th1 type inflammatory response with oxidative stress, which can determine adverse effects on human health.

c. The effect on intestinal microflora

Another mechanism that can influence air pollutant action on intestinal mucosa is the effect on intestinal flora. The intestinal flora has a key role in inflammatory bowel diseases (38). It was proven in animal experiments that inflammatory bowel diseases do not appear if the mice are held in a sterile environment. The intestinal flora of patients with inflammatory bowel diseases is different than that of healthy subjects (39). The genetic loci associated with IBDs suggest the important role of the relation between the intestinal immune system and intestinal flora in the pathogenesis of inflammatory bowel diseases (40).

The structure of the intestinal flora can be affected by pollutants, especially heavy metals like lead and cadmium (39-42), which reduce taxonomic diversity.

Intestinal bowel diseases:
gene – environment relationship

The discovery of the genetic implication in inflammatory bowel diseases etiopathogenesis represented an important element. Still, only 20% of the cases can be thus explained. It is suggested that environmental factors contribute more than the genetic component in IBD pathogenesis (43). The importance of environmental factors is proven especially in children (44).

Up to this moment there are no studies to directly link and describe how the genetic and environmental factors act together in IBDs.

A study was performed on 310 patients with Crohn identified NOD2 gene as the most significant gene associated with Crohn's disease in smokers (45).

CONCLUSIONS

Up to this moment there are several indicators which show that pollution can have a negative impact on the intestinal tract. However, up to this moment the evidence is limited. The current studies have many limitations that must be eliminated and many confusion factors that must be measured and corrected so that the specific factors can be correctly evaluated for intestinal diseases.

This can include identifying and evaluating the interaction between genetic factors and environmental factors.

A careful interpretation must be done of the data that evaluates the relation between air pollution and inflammatory intestinal diseases and it must represent an incentive towards the continuation of research in this direction.

Studies on animals must verify the biologic plausibility of obtained data.

Air pollution with particles as well as gas and heavy metals can represent an element which cannot be ignored in determining the etiopathogenesis and evolution of inflammatory bowel diseases (46, 47).

NEWS

BIOFILM-INHIBITORY COMPOUNDS AGAINST *PSEUDOMONAS AERUGINOSA* FROM BURDOCK LEAF

In a study by Lou Z *et al,* basic anti-biofilm profile data for the compounds in burdock leaf were analyzed and a convenient method for fast screening of anti-biofilm compounds from natural plants was provided. According to this study, 34% ethanol elution fraction of burdock leaf could completely inhibit biofilm formation of *Pseudomonas aeruginosa* at 1 mg·mL(-1). Ultra-performance liquid chromatography-mass spectrometry (UPLC-MS) was used to determine the chemical composition of burdock leaf fraction and to obtain the metabolic fingerprints of burdock leaf fractions before and after inhibiting *P. aeruginosa* biofilm. The analysis identified 11 active compounds: chlorogenic acid, caffeic acid, p-coumaric acid, quercetin, ursolic acid, rutin, cynarin, luteolin, crocin, benzoic acid, and Tenacissoside I. Partial least squares discriminant analysis (PLS-DA) of the metabolic fingerprints showed that, among 81 compounds that were screened as potential anti-biofilm ingredients, rutin, ursolic acid, caffeic acid, p-coumaric acid and quercetin are the main anti-biofilm compounds in burdock leaf (Lou Z, Tang Y, Song X, Wang H. Metabolomics-Based Screening of Biofilm-Inhibitory Compounds against Pseudomonas aeruginosa from Burdock Leaf. Molecules. 2015;20(9):16266-77. doi: 10.3390/molecules200916266).

DETECTION OF HUMAN PAPILLOMA VIRUS IN HEAD AND NECK CANCERS: A LITERATURE REVIEW (Abstract): Human papilloma viruses (HPV) are the most common sexually transmitted viruses. There is mounting evidence that incriminates HPV as a risk factor for malignant transformation of oropharyngeal epithelium. In 2011 the International Research Agency of Cancer and National Cancer Institute (USA) declared HPV-16 as an independent risk factor for oropharyngeal squamous cell carcinoma (OPSCC). Leaders in the field of HPV research admit that this subtype of head and neck cancer is a sexually transmitted entity and its global incidence is on the rise. In the 1980s, clinicians observed a new group of patients with head and neck squamous cell carcinoma (HNSCC) independent of tobacco smoking or alcohol use. The new HNSCC patient is a middle-aged man, non-smoker, non-drinker with higher social status and the suspected risk factors for HNSCC being related to sexual practices (oral sex, multiple sexual partners, unprotected sex and drug use). Routine HPV testing of HNSCC patients is seriously considered as HPV-positive oropharyngeal cancers comprise a distinct molecular, clinical and pathologic entity that has a markedly better prognosis than HPV-negative oropharyngeal cancers. The current treatment protocols for OPSCC include radiation, chemo-therapy and surgery alone or in combination, involving high toxicity levels. Future therapeutic concepts for OPSCC may be personalized in relation to HPV-status to avoid unnecessary toxicity. The current review summarizes the contemporary trends in the diagnosis of HPV-related head and neck cancers, presenting the advantages and disadvantages of the main methods. **Keywords:** HEAD AND NECK CANCER, HPV TESTING, BIOMARKERS

Papillomaviridae (reclassified in 2004) are a family of small double-stranded DNA viruses that infect warm-blooded vertebrates (1). Papillomaviruses infect different species of mammals and also distantly related hosts such as marsupials and birds (2). Traditionally HPVs has been classified in "types" based on phylogenetic analyses of the L1 gene, which is the most conserved gene in PVs. Based on their tropism the HPVs have also been grouped into mucosal or cutaneous types. Mucosal HPV types designated as "high-risk" (HR) types, isolated preferentially from malignant tumors are: 16, 18, 31, 33, 34, 35, 39, 45, 51, 52, 56, 58, 59, 66, 68 and 70. The "low-risk" (LR) types (HPV 6, 11, 42, 43 and 44) are founded in benign genital warts and other non-malignant lesions (1, 2).

The causative role of HPV in cervical

cancer is well established. Approximately 70% of cervical cancers worldwide occur due to HR-HPV types 16/18 infection (3). The exact molecular mechanism responsible for malignant transformation is still unknown. The HPV oncogenic proteins E6 and E7 are incriminated in this process. Persistent infection with HR-HPV is a necessary but not sufficient cause of this cancer, which develops over a long period through precursor lesions. It may pass as much as 20 years between the initial HPV infection and clinical occurrence of cancer (4). In women with normal cervical cytology findings the estimated global HPV prevalence is 11.7% and the most common types are HPV-16 (3.2%), HPV-18 (1.4%), HPV-52 (0.9%), HPV-31 (0.8%) and HPV-58 (0.7%) (5).

Romania has the highest incidence of cancer in Europe, 23.9/100,000. There are 4,343 new cervical cancer cases each year and 1,909 cervical cancer deaths. HPV prevalence among women with or without cervical lesions in the Northeastern region of Romania is 37.4% and the most frequent types are: 16 (10.5%), 53 (5.44%), 51 (5.05%), 52 (4.08%), 18 (2.91%) and 31 (2.73%) (6, 7).

HPV INVOLVEMENT IN HEAD AND NECK CANCER

The involvement of HPV in head and neck cancers was suggested for the first time in 1983 by *Syrjanenet al.* (8). The numerous studies dedicated to test this theory supported HPV involvement on the basis of: morphological similarities between genital and oropharyngeal epithelia, broad epithelial tropism of HPV, detection of HR-HPV genotypes in samples of oropharyngeal squamous cell carcinoma (OPSCC), and the HPV-induced immortalization of human oral keratinocytes *in vitro*. In 2011 the International Research Agency of Cancer and National Cancer Institute (USA) declared HPV-16 as an independent risk factor for oropharyngeal squamous cell carcinoma (OPSCC) (9). Experts in the field of HPV research admit that this subset of head and neck cancers is a sexually transmitted entity with an increasing global incidence. A growing body of evidence is supporting that HPV is responsible for approximately 20% of oral cancers and 60-80% of them are squamous cell carcinomas (10, 11).

In the 1980s, clinicians observed a new group of patients with HNSCC independent of tobacco smoking or alcohol use (12). The new HNSCC patient was a middle-age man, non-smoker, non-drinker with higher social status and the suspected risk factors were related to sexual practices (oral sex, multiple sexual partners, unprotected sex and drug use) (13-16).

HNSCC is the sixth most common malignant tumor worldwide with approximately 650,000 new cases diagnosed each year. While the reported incidence rate for all head and neck carcinomas is decreasing and the rates of coincident identification of oncogenic HPV as a new risk factor for OPSCC is increasing, it is obvious that a virus-related cancer epidemic is discussed (16-18). The involvement of oncogenic HPV types was clearly demonstrated only in cancers arising from the oropharynx (especially palatine and lingual tonsils). Romania is lacking HPV-related OPSCC studies. HR-HPV can be found in the oropharynx of healthy subjects and it is very important to differentiate between high-risk and low-risk HPV-types. Indeed, oral infection with HR-HPV types increases the odds ratio for developing oropharyngeal

cancer. In a recent systemic review of the literature the pooled prevalence of oral HPV in healthy individuals was found to be 4.5% with 3.5% of them having oncogenic HPV types (19). However, in the tonsils of healthy people the incidence of oncogenic HPV was only 1% (20).

Very often these tumors are diagnosed at an advanced stage, with an enormous impact on 5-year survival rate (80% for early-stage disease and only 20% for late-stage disease). In contrast to skin cancer screening where visual examination has high sensitivity (93%) and specificity (98%) the detection of oral cancers and premalignant lesions by conventional visual and tactile examination is problematic due to the complex anatomy of the oropharynx. Therefore, adjunctive screening tests are desperately needed (21).

MAJOR DIFFERENCES BETWEEN HNSCC BY HPV STATUS

HPV-positive oropharyngeal cancers comprise a distinct molecular, clinical and pathologic disease entity that has a markedly improved prognosis compared to HPV-negative oropharyngeal cancers**.** In HPV-negative OPSCC genetic alterations lead to mutations in p53 and retinoblastoma (pRb) tumor suppressor genes and also loss of heterozygosity. In contrast, HPV-positive cancers harbor the wild type of p53 gene, p16 is upregulated and pRb is down regulated (22, 23). Many researchers are looking for a predictive transcriptomic signature of oropharyngeal cancer according to HPV status in order to develop new reliable biomarkers for screening and early detection of OPSCC (24). Also, HPV-positive OPSCCs are strongly infiltrated by lymphocytes, are predominantly non-keratinizing squamous carcinomas and are described as poorly differentiated or basaloid carcinomas. The contrary facts are available for HPV-negative OPSCC (25). Also, the clinical response to therapy and overall survival are improved (a 28-58% reduction in the risk of death) for HPV-positive compared to HPV-negative cancers (26).

DIAGNOSIS OF HPV-POSITIVE HNSCC

At the moment, there is no consensus on the optimal algorithm to identify HPV-positive HNSCCs (Table I). Common practices include the detection of p16 protein through immunohistochemistry as well as HPV genetic material. Accurate HPV detection and typing is based on nucleic probe technology as HPVs cannot be cultured (27). At present HPV detection tests are included in three large categories: nucleic acid-hybridization, signal amplification and nucleic-acids amplification assays. In this review we will not address HPV serology tests (inconsistent seroconversion rates) and immunohistochemical detection of E6 and E7proteins (expressed at very different levels) since these methods are lacking sensitivity and therefore their routine implementation is of limited value (28, 29).

Nucleic acid-hybridization assays include techniques such as Southern blotting, *in situ* hybridization (ISH) and dot-blot hybridization. The advantage of ISH is its high specificity, the detection of HPV DNA is site-specific and has the ability to differentiate between episomal and integrated DNA. ISH is time-consuming, requires large amount of purified DNA and the sensitivity is low (83%) with an estimated 13-14% false-negative rate. All these makes ISH improper for routine clinical use (29).

TABLE I

Sensitivity and specificity of main diagnostic methods used in HPV infection detection, related with OPSCC

Authors Year (reference)	Sample size	Detection method	Sensitivity	Specificity
Schache et all (41) 2013	79 FFPE	RNA Scope (RNA ISH) and DNA qRT-PCR	97% 91%	93% 87%
Chaudhary et all (30) 2010	222 OSCC	Hybrid capture 2 Ts-PCR E6 primers	DR=32,4% DR=31,4%	-
Thavaraj et all (42) 2011	142 tonsil SCC	P16+HPV DNA ISH P16+PCR GP5+/6+ P16+ISH+PCR	Dr=53% Dr=61% Dr=63%	-
Ahn et all (44) 2014	81OPSCC saliva + plasma	Q-RT-PCR saliva Q-RT-PCR plasma	S+P=76 S or	S+P=100% +p.v=100%

Abbreviations: FFPE=formalin fixed paraffin embedded, ISH=in situ hybridization, qPCR= quantitative polymerase chain reaction, Ts=type-specific, OSCC=oral squamous cell carcinoma, SCC=squamous cell carcinoma, S=saliva and P=plasma, Dr=detection rate

Signal amplification. At the moment two signal amplification assays are commercially available and are approved by the Food and Drug Administration (FDA). These kits are: *Digene HPV test* using *Hybrid Capture 2* (hc2) technology and the *Cervista HR HPV* assay (29).

Hc2 detects 13 HR-HPV types (16, 18, 31, 33, 35, 39, 45, 51, 52, 56, 58, 59 and 68) and 5 low-risk types (6, 11, 42, 43 and 44) based on the hybridization of the target HPV-DNA to labeled RNA probes in solution. This assay was not designed for genotyping single HPV type and distinguishes only between high-risk and low-risk groups. Also this test uses full-genome RNA probes complementary to HPV DNA, specific antibodies, signal amplification and chemiluminescent detection (28, 29). *Chaudhary et al*. found a slight difference between the positivity rates of HR-HPV infection detected by hc2 and PCR method in OSCC, with a better sensitivity attributed to hc2 assay (30).

The *Cervista HPV signal amplification* assay (FDA approval in 2009) detects 14 HR-HPV types as a group (16, 18, 31, 33, 35, 39, 45, 51, 52, 56, 58, 59, 66 and 68) in addition to simultaneous HPV-16/18 detection. Also, this method demonstrates a lower false-positive rate, high sensitivity and specificity to genotyping HPV-16/18 (28, 29, 31).

PCR-based techniques can be *consensus* or type specific detection methods. Although it is very important to discriminate between HR and LR HPV types, genotyping of a single HPV type has a greater significance not only for research purposes but also for clinical findings since in persistent infections with HPV-16/18 the risk of a precancerous lesion is estimated at 10-15% and 3% for all other HPV strains combined (29, 32).

At the moment there are different primer sets for HPV detection in consideration to HPV biology. The most commonly used primer pair sets are MY09/MY11, GP5/GP6 and SPF10 LiPA sets which due to the high variability of HPVs (189 types)

target the L1 open reading frame (ORF) which is highly conserved among HPV strains. Upon viral integration into the host genome, the L1 ORF of the HPV genome may be deleted, consequently resulting in decreased sensitivity of HPV detection. PCR strategies targeting sequences retained upon viral host genome integration can offer more sensitivity for HPV detection. Such sequences are E6 and E7 HPV oncogenes. This was proved by a study on HPV detection in anal carcinoma where the HPV detection rate with L1 consensus primers was found to be 16%, whereas with strain-specific E6 primers the HPV positivity was 46% (28, 33-35). Also, in the integration process of HPV genome into the host genome, very often occur breaking points at E1 and/or E2 ORF (regulators of E6 and E7 protein expression) resulting in gene disruptions. When E2 gene is disrupted, the designed primers targeting E2 gene and aiming the entire E2 amplification will fail. Therefore primer sets targeting shorter regions will enhance the sensitivity of the method (35-37).

The drawbacks of conventional PCR methods are: low specificity, not site- specific like *in situ* hybridization assay (the detected HPV-DNA can originate from both malignant cells and surrounding non-transformed tissue), does not differentiate episomal from integrated HPV-DNA and also implies technical difficulties in performing. At the moment, there are no standardized PCR-based techniques leading to discordances in analytical sensitivities and specificities between laboratories. Furthermore, the genetic variation of HPV types and other unknown yet genomic features of HPVs are responsible for false-negative results (27, 29, 35, 38).

Equally important is the read-out system used to detect and visualize the PCR products. Novel PCR-based methods and commercially available kits improved their performance *via* more powerful read-out systems and implying hybridization technology. Most read-systems use hybridization techniques of PCR products to labeled oligonucleotide probes. The reverse line hybridization technique uses a solid support with a biotin-labeled PCR product hybridized to an array of immobilized oligonucleotide probes. Ultimately the visualization is performed through colorimetric or fluorescent staining procedures. Another read-out system incriminates an enzyme immunoassay method which cannot detect single genotype. This technique imply capturing of biotinylated PCR products to streptavidin-coated microplate wells and then hybridization with labeled oligonucleotide probes specific for the HPV types of interest (28, 30, 35, 38).

The real-time PCR (RT-PCR) has more analytical power this is higher sensitivity, and also provides a quantitative analysis of viral load. The quantification of targeted DNA is done *via* colorimetric markers during PCR amplification. High analytical sensitivity (a few copies of HPV DNA) does not translate into more clinical relevance because of presence of latent, non-productive and transient (not uncommon) HPV infections. On the other hand, the quantification of viral load and adjusting the cut-off viral load results in increased specificity and clinical relevance of the results of RT-PCR investigation. For a cut-off viral load >0.5 copies per cell, Smeets *et al* estimated the sensitivity at 92% and the specificity at 97%. Therefore false-negatives still exist (28, 35, 37, 39).

Detection of HPV mRNA in tumor samples is currently considered “the gold

standard". The clinical significance of HPV E6/E7 mRNA detection is greater than that of HPV-DNA detection since this provides evidence of active gene transcription, the HPV infection is a productive one and the virus is an etiological factor. Several authors reported that 14-50% of oropharyngeal cancers found to be HPV-DNA-positive mainly through PCR-based techniques were negative for E6/E7 mRNA expression, meaning that the false-positive rate was 14-50% and the specificity 50-86% (35, 40). "Why is specificity important?" Even though the HPV-status does not influence the treatment plan for OPSCC, the impact of a HPV false-positive test of a cervical specimen in female patients is much bigger often leading to over treatment and psychological discomfort. A drawback of HPV E6/E7 mRNA detection is that it is not site specific, but performing RNA *in situ* hybridization proves that HPV E6/E7 mRNA originates from HPV-induced malignant cells. These techniques are time consuming, expensive, and too laborious for use in routine screening (35, 41).

CONCLUSIONS

Even though the relation between HPV infection and HNSCC was formulated in 1983, over the years experts in HPV field have not yet reached a clear conclusion regarding the best techniques for the detection of premalignant lesions in order to implement effective methods of treatment. RT-PCR, detection of HPV mRNA and *in situ* hybridization of mRNA seems to be the most useful methods.

Future large-scale anti-HPV vaccination program worldwide will be able to decrease the incidence of HR HPV infection and the risk of OPSCC and HNSCC as well.

CONFIDENTIALITY PRINCIPLES IN PSYCHIATRY

B. Carasevici

University of Medicine and Pharmacy "Grigore T. Popa" – Iaşi

Department of Preventive Medicine and Interdisciplinarity

CONFIDENTIALITY PRINCIPLES IN PSYCHIATRY (Abstract): Confidentiality stands out in psychiatry through its multiple connotations as an intrinsic necessity in the ethics of professional relationships. Thus it represents an important characteristic of this profession and at the same time a stringent request which, through its specificity, implies a direct contact with persons in need for help. Despite being inserted in professional codes and legislative systems, confidentiality in psychiatry is far from being considered a clarified matter and does not stand aside from ethical controversy. Keeping the professional secret is often a hard task due to the pressure of the law or of other professional groups who can bring multiple justifications, including that of action for the benefit of society. The therapist is often submitted to a tension caused on the one hand by the promise of keeping the professional secret and on the other hand by multiple requests of breaking the confidentiality. So the problem of confidentiality in Psychiatry deserves special attention because in this profession, more than in other branches of medicine, the gain of the patient's trust is essential in the psychotherapeutic relationship. **Keywords:** ETHICAL CONTROVERSY, PROFESSIONAL GROUPS, GAIN OF TRUST, PSYCHOTHERAPEUTICAL RELATIONSHIP

The idea of protecting the confidential character of communication between physician and patient was first expressed in the Hippocratic Oath, while the guarantee of confidentiality through law appeared in the English legislation as early as the 17th century. Moreover, the ethical principle of confidentiality was at the core of Percival's Code of Medical Ethics, representing the starting point for both the American Medical Society and the British Medical Society. From a legislative viewpoint there are, however, significant differences regarding the limitation of medical confidentiality within the legislative systems of different countries. Consequently, despite being inserted in professional codes and legislative systems, confidentiality could hardly be regarded as a clarified matter and often makes the subject of controversy. Keeping the professional secret is often a difficult challenge due to the pressure coming from either the legislative system or from certain professional groups that could provide a whole range of justifications, including that of action for the benefit of society (1, 2). The psychiatrist is thus challenged by an ethical tension caused, on the one hand by his engagement to keep the professional secret and on the other hand by the multiple requests of breach of confidentiality that she/he constantly receives.

THE DOCTOR - PATIENT RELATIONSHIP

Confidentiality essentially defines, beyond any legislative aspects, the professional relationship between doctor and patient. More specifically than in any other branch of medicine, confidentiality is essential in psychiatry firstly because it helps the patient engages in the psychotherapeutic relationship. Only that patient who fully trusts his/her therapist will reveal his/her most intimate thoughts, intentions, doubts or states of mind. In the Hippocratic times, although doctors had very few therapeutic means, they were able to offer the patients trust, hope and inspiration that helped them recover. These less tangible approaches can be hardly found in the over-technologies medical practice of the present day. The therapist's role is limited, according to the reductionist model strictly based on biological dimensions, to correcting certain organic and functional deficiencies by means of pharmacological and surgical methods. Being guided by these aspects, some voices even claim that Hippocratic medicine would be out-of-date and unable to overpass its symbolic condition. However, from an ethical point of view, the Hippocratic tradition is a key element in medicine and defines the human context necessary for the application of all these new technologies.

The relationship between the psychiatrist and the patient, on the one hand, as well as between the psychiatrist and the patient's family is crucial in achieving efficient psychotherapy, in increasing the patient's trust in the therapist's competence and his/her belief that the condition can be either improved or cured. Nowadays, due to the new technologies and paraclinical investigations possibilities, patients show an increased tendency to believe that the diagnosis and cure of a certain condition depend mainly on complicated tests and investigations and the miraculous effect of sophisticated treatment schemes. The therapist's intervention and contribution seem to be regarded as secondary and less important (3). This results in a state of tension and concern, as the patient searches for and requires more and more tests and treatments, the psychotherapeutic contact between doctor and patient being thus negatively impacted. In this context, the relationship between the therapist and the patient should be reconsidered, by trying to re-establish an affective contact and increase the role of psychotherapy, which should be mediated by means of other investigations. As well as this, hospital conditions should be improved, the trauma produced by hospital commitment and by the implications of psychiatric diagnosis should be reduced to a minimum and the best possible social and family integration should be constantly attempted. In this context, the psychiatrist's duty is to protect the patient, to keep the professional secret and treat the diagnosed condition with competence, resoluteness and optimism. Such an attitude is meant to increase the patient's confidence in the therapist's competence and expertise, the moral support offered to the patient motivating the latter to cooperate in regaining his/her hope of recovery and reintegration in his/her social, family and professional life.

Confidentiality is philosophically founded and supported by arguments and justifications belonging to various theoretical concepts. Regarded from the medical ethics perspective these concepts are related to ethical and philosophical dimensions faithfully mirrored by social and community elements.

THE UTILITARIAN THEORY

As far as the utilitarian theory is concerned, breach of confidentiality is only permitted when the respective breach results in producing a better effect or a less harmful effect upon the society as compared to keeping the professional secret. Any society is interested in ensuring health benefits for all its members, and guaranteeing the confidentiality of the medical act is meant to encourage the population in requiring health assistance. This particular aspect is more obvious in the case of a psychiatric condition, as the nature of the condition itself can label the patient in a socially stigmatizing manner. This is why psychiatric conditions are regarded with more conspicuous caution and prejudice by the rest of the population.

It was repeatedly noticed that the society's attitude towards the psychiatric patient and his/her condition directly impacts upon the psychiatric assistance (4). Depending on the hesitations and the prejudices influencing the community or the patient himself/ herself, the patient postpones his visit to the psychiatrist, psychiatric hospital or even the ambulatory medical unit. Unconventional treatments are often preferred, which leads to wrong diagnosis or inaccurate evaluation of the physical suffering, delays the administration of adequate therapy and hides the sometimes very severe evolution of the condition. This situation is mainly due to the reticence of the social environment towards the patient who was committed to a psychiatric hospital and received a psychiatric condition diagnosis (5). This is why the patient should feel safe under the shelter of confidentiality so that he is able to reveal certain information and help the therapist decipher his/her suffering. On the other hand, the therapist must maintain confidentiality of all information and data received from the patient and not only of that information that is relevant for diagnosis or therapy.

THE THEORY OF AUTONOMY

The theory of autonomy focuses on the mandatory dimension of confidentiality supporting the notion of individual autonomy that include every person's right to privacy and secrecy as far as personal data and information are concerned. The obligation to respect confidentiality can be reinforced by the doctor's promise to the patient to treat all information as confidential. In this case, as opposed to the utilitarian theory, there is no motivation whatsoever for breaking the promise of confidentiality. Some modern approaches of this theory state that confidentiality may be broken in situations in which keeping the information secret would result in causing harm to other people or the patient himself/herself. The justification of such an action is based on the principle that no right is absolute as long as the one who benefits from that specific right would infringe other norms or regulations that would cause harm to other people or to that individual himself/herself.

However, other approaches argument and plead in favor of the absolute right to confidentiality motivating that this would bring infinitely more benefits than any breach of confidentiality required by particular cases and situations. Immediate benefits can be followed by negative long-term consequences and especially by a decrease in medical assistance consumption that would in turn have a negative impact upon the general health of the population (6). Another argument would be the improper situation a therapist would put him-

self/herself into when revealing confidential information for political and legal reasons rather than medical ones.

THE SOCIAL CONTRACT THEORY

Another theory to be considered is the social contract theory that states that any traditional generally accepted practice can be formally protected by the law. This can also be applied to confidentiality, which represents an ancient medical tradition. The obligation to keep the professional secret and confidentiality is part of the social contract concluded between the doctor and his/her patient.

PARTICULAR SITUATIONS

As far as dilemmas raised by particular situations are concerned, the therapist finds himself/herself in a very delicate position: on the one hand s/he must value and respect confidentiality in his/her relationship with the patient and on the other hand s/he must act in compliance with the provisions of the law respect his/her duty as a citizen. There are cases in which breach of confidentiality as required by the law is only performed after the person involved formally consents. This category includes situations of legal obligation to reveal information on an individual's state of mental and physical health, such as medical reports or examinations required for hiring in a new workplace, obtaining a driver's licence or a handgun carry permit.

As opposed to the situations mentioned above, there are countless cases where evaluation is controversial. The necessity to break confidentiality is often motivated by the need of social protection (7). First of all there are frequent cases of degradation of family relations in which usually the wife, although physically and/or emotionally abused does not want to press charges on her violent husband, although her suffering is evidently perpetuated. Equally controversial are children abuse cases. Although it is generally accepted that these cases be reported once they are discovered, it is yet unclear if reporting the case actually solves the problem. Experience sadly shows that limited resources within the family is the most common cause for which children are required participate in certain activities while their school attendance drops or their access to education is limited. In such cases, simply reporting the situation to relevant authorities does not solve the issue. As well as this, children might consequently become victims of physical and psychic violence or even sexual abuse, especially when parents are alcoholics or drug addicts. In these cases besides reporting the situation to authorities, parents should be taken into social care and receive specialized assistance

SPECIAL CASES

Drug users are one of the special cases. As far as they are concerned, in many countries the law stipulates that the therapists should report them, for their own protection. That is why the drug users give up medical help altogether, so their addiction is not revealed. Drug or alcohol addiction should consequently be entitled to strict confidentiality, mainly due to the stigmatizing character of the addiction, of which the patient is fully aware. The patient's desire to remain anonymous often prevails over his/her desire to get help. This is the very reason for which various associations dealing with the protection and rehabilitation of alcoholics are called *Alcoholics Anonymous Associations* (8).

Another special case would be that of a psychiatrist who finds out from a patient that the latter has committed a crime. Any supporter of the absolute right to confidentiality would plead in favor of keeping the professional secret in this specific case. This is actually one of those instances in which the relationship between therapist and patient resembles the one between priest and parishioner under the confession oath (9). Supporters of the utilitarian theory would most probably argue against this position, as, according to their belief, doctors' duty is to contribute to the wellbeing and protection of society, as any other citizen.

On the other hand, breaking confidentiality every time a therapist senses a potential danger would only estrange and keep at a distance the patients who, feeling their trust betrayed, would no longer require the psychiatrist's help. One should not disregard the strictly therapeutic aspect of working off one's tensions by means of free and uncompromised expression of all thoughts, feelings and imagination that a patient frees himself/herself of during therapy. More than that, the absolute trust and reliance a patient has towards his/her therapist determines that patient to respect all therapeutic indications; when confidentiality is uncertain the patient would not be motivated to follow therapeutic indications properly. Thus, the only chance the psychiatrist has for intervention in particularly difficult and potentially dangerous cases, namely hospital commitment and treatment acceptance, would be totally compromised (10, 11, 12).

CONCLUSIONS

Many psychiatrists are revolted against this pressure to become defendants of public order rather than therapists, especially since violence prediction is not a very exact coordinate. Potential dangerousness may or may not turn into violent behaviour, and it can be manifested in so many various ways. Most legal systems do not state clearly the situations in which the psychiatrist shall warn the authorities. This attitude would probably be justified only in obvious and extreme cases where a person's or a private property's integrity would be endangered. If we also take into account the possibility of a relative identity of the potential victim or a vague identification of that victim, the next question arises: How should the therapist act in order to prevent an event? The rightest attitude from a medical and ethical viewpoint would probably be to simplify the compulsory commitment procedure.

In psychiatry, confidentiality arises thus, due to its multiple connotations, as an intrinsic necessity within professional relations ethics. This principle represents an important characteristic that governs many other professions and an undeniably essential demand in professions that imply a direct contact with people who seek some kind of professional help. In psychiatry, confidentiality and keeping the information provided by the patient secret become thus an implicit condition of professionalism, representing at the same time a guarantee for the confidence of the patient in the respective professional service.

EZETIMIBE/STATIN COMBINATION THERAPY TO TREAT PATIENTS WITH TYPE 2 DIABETES

Diabetes mellitus is the most common serious metabolic disorder and it is considered to be one of the five leading causes of death in the world. Patients with diabetes present a cardiovascular risk two to four times higher than non/diabetes population. An important factor in cardiovascular complications is hyperlipidemia. Diabetic dyslipidemia is characterized by the so-called atherogenic lipid triad. The aim of this study was to investigate the efficacy of add-on ezetimibe therapy in cholesterol lowering for patients with type 2 diabetes and not controlled by statin therapy. The results of this study showed that adding ezetimibe to statin in add-on trials provided a relative decrease in LDL-cholesterol from baseline of 23.4% compared to statin monotherapy. This fact suggests that patients who poorly respond to statins may be more responsive to cholesterol absorption inhibitors such as ezetimibe. The study supports the hypothesis that an high effect of cholesterol-lowering can be achieved by administration of a minimum dose of statin with ezetimibe, a higher response to that obtained by administration of statin monotherapy maximum doses. Ezetimibe decrease the postprandial elevations of chylomicron cholesterol and triglycerides; after combination therapy with atorvastatin it induced a greater decrease in post-prandial TG levels. These favorable effects have been observed also in association with simvastatin, a good influence on fasting and postprandial triglyceride-rich lipoproteins in patients with type 2 diabetes, by favoring the production of less atherogenic cholesterol-poor chylomicrons and VLDL particles. Ezetimibe alone or in association with simvastatin had favorable effects on the removal of radio labeled chylomicron-like emulsions from plasma in patients with coronary heart disease. It can be concluded that ezetimibe therapy, in combination with statins, provide greater biological beneficial effects, compared to statin monotherapy, in patients with type 2 diabetes (Farnier M, Ezetimibe/statin combination therapy to treat patients with type 2 diabetes. *Atherosclerosis Supp*, 2015; 17: 2-8)

DEVELOPMENT OF A NEW RP-HPLC METHOD FOR ONDANSETRON DETERMINATION IN INJECTABLE FORMULATIONS (Abstract): The aim of this study was to develop a simple, rapid and efficient reversed phase HPLC-UV method for ondansetron assay in injectable dosage forms. **Material and methods**: Analyses were performed with the aid of an 1100 series HPLC system (Agilent Technologies USA) by using an Inertsil ODS 150x4.6 mm column with 3 µm particle size (GL Sciences, Japan), operated at 45°C temperature. The mobile phase consisted of 70% KH_2PO_4 20 mM with triethylammonium phosphate and 30% acetonitrile and it was delivered at a flow rate of 1.5 mL/min. The detection was done at 216 nm. **Results**: Different chromatographic conditions were tested to reduce the time of analysis and to improve the chromatographic efficiency, with symmetry factor between 0.8-1.2. After establishing the optimal analytical conditions, analytical performance studies have been carried out. Linearity study reveals a good correlation in the concentration range 30 µg/mL – 70 µg/mL. Method accuracy and precision were less than 2%. Under the HPLC-UV specified conditions, ondansetron hydrochloride was separated with a retention time less than 2 minutes, with peak symmetry of 0.87 and adequate results at the validation tests. **Conclusions**: The proposed method allows a rapid analysis of ondansetron from injections by using a simple reversed stationary phase. **Keywords***:* ONDANSETRON, HPLC-UV, INJECTIONS.

Ondansetron hydrochloride is a carbazole derivative with a imidazolilmethyl group on position 3 with the chemical name 1,2,3,9-tetrahydro-9-methyl-3-[(2-methyl-1H-imidazol-1-yl) methyl]-4H-carbazol-4-one hydrochloride. It is used to prevent nausea and vomiting caused by surgery, cancer chemotherapy or radiation treatment. The racemic form of ondansetron is a selective, competitive serotonin 5-HT3 receptor antagonist in the gastrointestinal tract as well as centrally. It is available as tablets, oral solutions, injections (1).

Ondansetron is a chiral molecule with one asymmetric carbon and it is used as racemate. It is a white or almost white powder, sparingly soluble in water and in alcohol, soluble in methanol, slightly soluble in methylene chloride (2-3). Ondansetron is less sensitive to temperature and moisture, it must be protected from light and neutral and alkaline pH influence

its stability (2).

Different methods regarding the assay of ondansetron hydrochloride are reported, many of them being reversed phase HPLC methods with octylsilyl, phenylsilica or TiO_2 as stationary phases and mixtures of polar solvents as mobile phases (4). Other studies are focused on simultaneous determination of ondansetron in combinations with the aid of HPLC technique, combinations such as ondansetron-famotidine, ondansetron-rabeprazol, idarubicin ondansetron in 0,9% natrium chloride, ondansetron-morphine (4-7). RP-HPLC with ions pairs was applied for the determination of ondansetron hydrochloride from pharmaceutical formulations, particularly the effect of sodium heptane sulfonate (8-10).

In the monography of Ondansetron hydrochloride from European Pharmacopoeia 8-th edition a HPLC method for separation and identification of ondansetron and his main impurities (Impurity A-H) is described by using a nitrile silica gel stationary phase with a mobile phase consisting of acetonitrile and sodium dihydrogen phosphate monohydrate adjusted to pH 5.4 with sodium hydroxide (3). Cyano phases has a strong dipole character that can interact with other dipoles on solutes and have moderate hydrophobic character from alkyl ligands. Their stability in comparison with C8 and C18 is moderate and it depends from one producer to another. For cyano phases the chemical bond to the silica surface is more accessible because of the small size of the ligand and it is unstable under hydrolytic conditions or can cause hydrolysis.

To develop a new HPLC method without using the official nitrile stationary phase and a complicate composition of mobile phase, a rapid and improved RP-HPLC method for ondansetron determination in injections is proposed by using a simple octadecyl column.

MATERIAL AND METHODS

Instruments and chromatographic conditions

Agilent Technologies 1100 series HPLC system, equipped with quaternary pump and UV-VIS detector. Column: Inertsil ODS 150x4.6 mm column (C18) with 3µm particle size (GL Sciences, Japan). Mobile phase was consisted of a solution of KH_2PO_4 (Merck) with triethylammonium phosphate TEAP (Sigma Aldrich) and acetonitrile ACN (LC Grade, Fluka). Final injection volume was 5 µl.

During method development, temperature of the column was varied between 35°C and 45°C, the flow rate between 1 mL/minute and 1.5 mL/minute. The tested wavelengths were 254 nm and 216 nm. The concentrations of phosphate and TEAP were varied between 10 and 20 mM and between 2 and 20 mM, respectively. The final chromatographic conditions were: 70% KH_2PO_4 20 mM with 20 mM TEAP and 30% ACN, flow rate 1.5 mL/min, temperature 45 °C, detection at 216 nm.

Reference substance and preparation of standard solutions

Ondansetron hydrochloride working standard (Glaxo SmithKline, UK) was used. Stoc solution preparation: an appropriate quantity of ondansetron hydrochloride dihydrate standard was dissolved with methanol (LC Grade, Sigma Aldrich) at the final concentration 100 µg/mL ondansetron.

The stock solution was further diluted to give standard solutions with concentrations between 30 and 70 µg/mL.

Sample preparation

The ondansetron injection, with 2

mg/mL ondansetron, was diluted with methanol at 50 µg/mL concentration before analysis.

RESULTS AND DISCUSSION

Different chromatographic conditions were tested to reduce the time of analysis, to improve the efficiency parameters for active pharmaceutical ingredient by taking into consideration a peak symmetry factor between 0.8-1.2 according to pharmacopoeia provisions (tab. I).

TABLE I

Tested chromatographic conditions during method development

No	Injection volume, µL	Mobile phase composition*		Flow rate, mL/min	t, °C	λ, nm	Symmetry
		70% aqueous phase					
		KH_2PO_4	TEAP				
1	10	20 mM	-	1	35	254	0.519
2	10	40 mM	-	1	35	254	0.52
3	10	10 mM	-	1	35	254	0,56
4	10	0	-	1	35	254	0.575
5	10	20 mM	2 mM	1	35	254	0.685
6	5	20 mM	2 mM	1	35	254	0.738
7	10	20 mM	6 mM	1	35	254	0.731
8	5	20 mM	6 mM	1	35	254	0.75
9	5	20 mM	6 mM	1	45	254	0.764
10	5	20 mM	10 mM	1	45	254	0.789
11	5	20 mM	10 mM	1.5	45	254	0.845
12	5	20 mM	20 mM	1	45	254	0.806
13	5	20 mM	20 mM	1	45	254	0.871
14	5	20 mM	20 mM	1.5	45	216	0.87

*the organic phase consisted of 30% ACN

In the first place the concentration of KH_2PO_4 was modified from 10 mM to 40 mM without TEAP proportions of the mobile phase components were 70% KH_2PO_4 at different concentration and 30% ACN, flow rate 1 mL/minute, detection at 254 nm, column temperature 35°C. In case of using KH_2PO_4 40 mM the ondansetron hydrochloride peak symmetry was 0.52 (fig. 1), for KH_2PO_4 10 mM the symmetry increases at 0.56, but still unsuitable for our study.

The presence of phosphate is important for higher, tighter and efficient peaks, a concentration of 20 mM KH_2PO_4 seems to be optimal, but also the mobile phase pH influence was studied, in this case we adjusted the pH with TEAP at 3.5, thus combining the pH influence and the presence of ammonium quaternary salt for the inhibition of residual interactions.

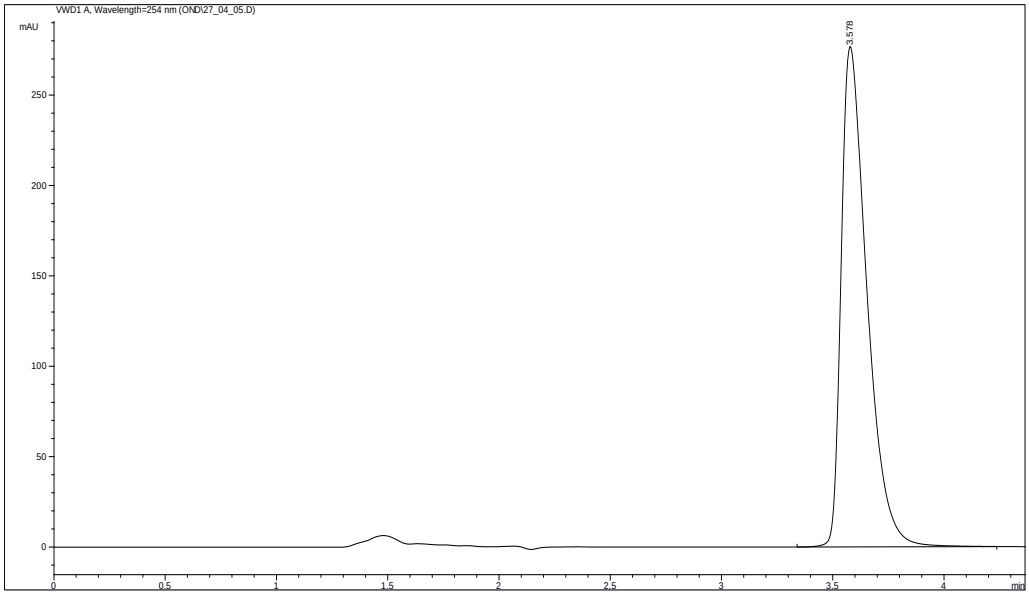

Fig. 1. Chromatogram of ondansetron hydrochloride standard solution 100 µg/mL, with mobile phase consisting of KH_2PO_4 40 mM 70%: ACN 30%, flow rate 1 mL/min, detection at 254 nm, separation temperature 35°C, peak symmetry 0.519.

The injection volume was also modified from 10 µl to 5µl, and the flow from 1 mL/minute to 1.5 mL/minute to improve peak symmetry. The separation temperature has a small influence on ondansentron hydrochloride peak symmetry, an increasing from 35°C at 45°C lead to better symmetry value 0,87. The detection was finally established at 216 nm, according to pharmacopoeia provision, and to detect any interference by using an unspecific detection wavelength (fig. 2).

To test the analytical performances of the developed method, linearity, accuracy and precision were investigated. For the linearity test, five levels of concentrations in five different series were analyzed by applying the final chromatographic conditions. The results are presented in table II.

There is a linear positive correlation between peaks areas and concentrations of ondansetron solutions, with the mean calibration curve Area = 18.49(±0.41)-3.40(±16.00), the correlation coefficient being greater than 0.998. A randomly distribution of residuals was obtained in ±2% range.

For precision test, the concordance of results from a range of 7 replicate quality control samples with the concentration 50 µg/mL of ondansetron hydrochloride was established, the RSD being 1.13%.

For the quantitative analysis of ondansetron from injectable dosage form, 2 mg/mL, the pooled sample was diluted with methanol at 50 µg/mL concentration, the analysis being performed in triplicate. No interference of excipients is expected being non-retainable substances under the proposed chromatographic conditions. A content of 104.5% was determined, in conclusion the sample is in accordance with Pharmacopoeia requirements regarding labelled content.

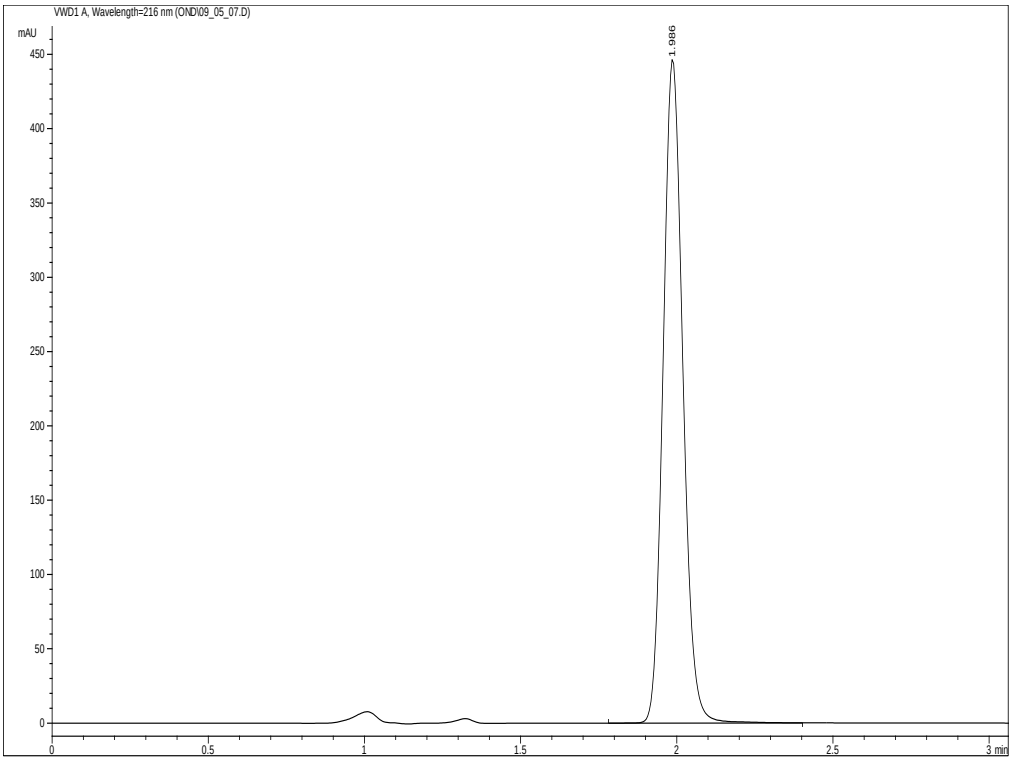

Fig. 2. Chromatogram of ondansetron hydrochloride standard solution 100 µg/mL, with mobile phase consisting of KH_2PO_4 20mM with TEAP 20mM 70%: ACN 30%, flow rate 1.5 mL/min, detection at 216 nm, separation temperature 45°C, injection volume 5 µL, peak symmetry 0.87**.**

TABLE II

Linearity test results

Theoretical concentration, g/mL	Found concentration, µg/mL					Average, g/mL	DSR%	Er%
	Series 1	Series 2	Series 3	Series 4	Series 5			
30.00	30.31	30.68	29.35	29.95	29.86	30.03	1.66	0.10
40.00	39.78	39.67	40.24	40.39	40.03	40.02	0.76	0.05
50.00	50.23	49.46	51.38	50.28	50.35	50.34	1.36	0.68
60.00	58.95	59.35	59.11	58.46	58.96	58.97	0.55	-1.72
70.00	70.73	70.84	69.92	70.92	70.6	70.60	0.57	0.86

CONCLUSIONS

The study proposed a rapid reversed phase HPLC-UV method for ondansetron assay with a good peak symmetry, by using

a C18 column, more available and less expensive than *Pharmacopoeia official* nitrile column, and a simple mobile phase. The developed method it was proven to be linear for the chosen concentration range and the quantitative analysis from injectable dosage forms was carried out with optimal results.

IS IT ENOUGH SCINTIGRAPHY FOR EVERYONE? A CROSS-SECTIONAL ANALYSIS REGARDING THE IMPACT OF JUSTICE IN THE DISTRIBUTION OF HEALTH CARE RESOURCES (Abstract): **Aims**: The aim of this study was to evaluate the influence of three demographic criteria: gender, age and education level on the patients that perform a scintigraphy. **Materials and Methods:** The cross-sectional study was applied to 220 patients to whom it was prescribed a scintigraphy by their treating physician. Of these, 74 were men and 145 women, 10 children and 210 adults. According to their education, 88 people did not graduate a high school, a total of 56 people graduated a high school, 27 persons graduated a college, 22 people had a university diploma and 26 people a PhD title. The chi-square test was used to analyze the frequencies for the measurable variables on a nominal scale. The significance threshold is considered to be 0.05, so, only the values which are smaller were taken into consideration. We presented and analyzed only the data that fulfill this condition. **Results and Discussion:** From our study it has been found that gender criterion played an important role in performing a scintigraphy for the first time. 71.6% of male patients were undergoing a scintigraphy for the first time. The frequency of exploration by scintigraphy is increasing if you are a female patient than if you are a male patient: chi-square calculated value is χ^2 (3)=12.398, p=0.006. From our study it has been found that age item plays an important role in the scintigraphy investigations for all the patients. The first scintigraphy was significantly performed in the 40-50 years old gap, whilst for the patients being aged over 60; they were probably not performing a first time scintigraphy. We did not find significant statistical differences in respect of the education level. **Conclusions**: So, we can conclude that access to that medical investigation is not depending on the socio-economic status of the patient, but in some occasions, the number and the frequency distribution of performing a scintigraphy depend on gender and age. We can also conclude that the principle of egalitarianism is fulfilled and so the justice principle in the distribution of health care resources must be re-evaluated. **Keywords:** SCINTIGRAPHY, CROSS-SECTIONAL STUDY, HEALTH CARE, JUSTICE PRINCIPLE.

As Oprea has showed (1), based on a Deaton's study (2), health care services are unevenly distributed. This debate must submit appropriate distribution of health services in the case of medical imaging techniques. But, does a barrier really exist

for patients to get access to those methods of investigation? From this point of view, a barrier could result from the fact that in the clinics of the public medical system, time resource (staff's programme at work) and material resource (the actual cost of an investigation) are finite. So, in many laboratories and imaging services, scheduling of patients is carried out with delays, many patients have to wait up to one week or more to have access to those investigations (3). This, in reality, led to a limitation of access to medical services apart for what European general rules state (4).

Not only the antagonism between egalitarianism - suficientism is involved in an imaging investigation. Sufficient or equal access to medical services as presented by Huzum (5) does not make a difference in the way the patient is properly investigated, even though patient access is limited by the time factor.

The patient access to complex investigation and/or with a high degree of novelty (6) stressed that health care distribution is influenced by SES (socio-economic status) (7). Despite the prevailing circumstances given by their level of education, from our study we have found, that a high percentage of those who turn to complex medical services (par excellence, CT, MRI, scintigraphy techniques), have had access to them. Generally, as it is known, a lower level of instruction places the subject in the category of those with precarious material level and with a weak access to medical resources (8).

MATERIAL AND METHODS

The present study was based on a questionnaire survey. The questionnaire contains 20 questions (items), including a series of questions regarding the person's demographics, such as gender, age, and level of education (item 20). The application of questionnaires was performed starting with March till the end of July 2014. Questionnaires were completed by patients in the Laboratory of Nuclear Medicine of St. Spiridon University Hospital of Iasi. Their consent was obtained in advance. The subjects were assured for the confidentiality of the responses, and they have been informed that they can refuse to complete the questionnaire at any time.

For the questionnaire used in this study the approval of the Ethics Committees of the Grigore T. Popa University of Medicine and Pharmacy of Iaşi and St. Spiridon University Emergency Hospital of Iaşi was requested and obtained.

The subjects of this research were 220 patients, to whom it was prescribed a scintigraphy by their treating physician. Of these, 74 were men and 145 women, 10 children and 210 adults. According to their education, 88 people performed less than high school education, a total of 56 people graduated a high school, 27 persons graduated a college, 22 people owned a university diploma and 26 people a PhD title. Depending on the age, the variable was represented by 6 persons aged 1-10 years old, 4 people with the age between 10 to 20 years old, 2 persons aged 20-30 years old, 12 people aged between 30 to 40 years old, 24 people aged between 40 to 50 years old, 61 persons aged 50 to 60 years old and 111 people aged over 60.

All the data acquired were analyzed using *SPSS* version 22.0 for Mac. We used a statistical technique called *SPSS* (Statistical Package for the Social Sciences) which is widely used in different fields, including the health sciences as well. The chi-square test was used to analyze the frequencies for the measurable variables on a nominal scale. In this method, the significance

threshold is considered to be 0.05, so, only the values which are smaller are statistically significant. We presented and interpreted only the data that fulfill that condition.

RESULTS AND DISCUSSION

For a more analytical presentation, the results to be interpreted were splited in three different criteria: gender, age and level of education (within item 20).

Gender criterion

Answering to the first item: *„Are you for the first time in the Laboratory of Nuclear Medicine?”,* 58.2 % of the subjects responded that they were performing a scintigraphy for the first time. If we undergo an analysis of the distribution of measurable variables frequencies of gender criterion (within item 20) with the first time performing a scintigraphy criterion (item 1) we obtained the following data (tab. I).

TABLE I

Analysis of gender of the patients with item 1

		Gender		
		Male	**Female**	**Total**
Item 1	**Yes**	53	75	128
	No	21	71	92
Total		74	146	220

Chi square analysis attests: $\chi 2$ (1) =8.524, p=0.004. Analyzing the results, we can observe that irrespective of the answer to item 1, there were more women than men who came to the Laboratory of Nuclear Medicine. On the other hand, if in the case of female patients, there were no significant differences between those who were for the first time and those who were not, for male patients we recorded significant differences. The figures show that 71.6 % of the male patients were for the first time in the laboratory, while 28.4 % of the male patients were, in fact, repeating the investigation.

The second item was: *„If your answer to item 1 was No, how many times have you performed a scintigraphy?”* Analyzing through *SPSS* the item 2 with the patient's gender-related item 20 we arrived to the following interpretation: there were no significant differences based on gender with regard to responses to item 2 and chi square test shows: $\chi 2$ (3)=2.927, p=0.403. However, by chi square adjustment we recorded a significant difference between female patients and male patients that answered they had performed once or those that answered they had performed twice a scintigraphy (tab. II).

TABLE II

Analysis of gender and the number of performed scintigraphies

		Gender		Total
		Male	**Female**	
Item 2	**Once**	14	40	54
	Twice	8	20	28
	More than twice	17	29	46
	It is not the case	35	57	92
Total		74	146	220

The third item was: *„If you have performed multiple scintigraphy investigations, which was their frequency?”* Analysis of frequencies for the variables item 3 with the patient's gender in the subitem 20, showed that there are significant differences in scintigraphy investigations, χ^2 (3) =12.398, p=0.006. The meaning of these calculated values is that for the patients who were investigated by scintigraphy only once, a higher frequency was found for female than for male patients (tab. III).

TABLE III

Analysis of gender and the frequency of performed scintigraphy criteria

		Gender		
		Male	**Female**	**Total**
Item 3	**Once a year**	17	64	81
	Twice a year	2	6	8
	More than twice a year	3	1	4
	It is not the case	52	75	127
Total		74	146	220

Combining the results of item 1 with item 5 ("At your arrival in the Laboratory of Nuclear Medicine, your diagnosis was already established by your treating doctor?"), as well as with patient's gender-related criterion (within item 20), it was found that only for female patients there are significant differences, $\chi^2(2)=10.953$, p=0.004. In this case, we noticed an increased likelihood for the female patients with previously established diagnosis and that were not for the first time in the Laboratory of Nuclear Medicine with all the other categories of patients (tab. IV).

TABLE IV

Analysis of first time presence (item 1) with previously established diagnosis (item 5) for females (within item 20)

		Item 5			Total
		Yes	**No**	**I don't know this**	
Item 1	**Yes**	54	9	12	75
	No	66	2	3	71
Total		120	11	15	146

Gender demographic analysis of item 20, applied to the resulting analysis of frequencies for variables in item 5 and item 3, pointed significant differences in female patients, $\chi^2(6)=24.913$, p=0.000, which attests that female patients perform with a much higher probability at least one scintigraphy per year, if their diagnosis is already indicated (tab. V).

TABLE V

Analysis of previously established diagnosis (item 5) with the annual frequency of scintigraphies (item 3) for female patients

		Item 5			Total
		Yes	**No**	**I don't know this**	
Item 3	**Once a year**	60	1	3	64
	Twice a year	6	0	0	6
	More than twice a year	0	1	0	1
	It is not the case	54	9	12	75
Total		120	11	15	146

Age criterion

From our study, age seems to play an important role in the scintigraphy investigations. If we perform an analysis of item 1 (first time in the laboratory) and with age gap (within item 20), chi square is: $\chi^2(6)=19.689$, p=0.003. The significance of this value shows that there were statistically significant differences by age criterion with regard to the fact of being or not for the first time in the Laboratory of Nuclear Medicine. Differences were found for category 40 to 50 years old and also for those over 60 years old. Thus, for the category 40-50 years of age, patients who were for the first time (75 %) were much more numerous than those who did not come for

the first time (25 %). For the patients over 60 years old, there were several cases of those that did not come for the first time (67.6 %) compared to those who came for their first time (32.4 %) (tab. VI).

Analyzing in terms of age, item 1 (first time performing a scintigraphy) and item 5 (diagnosis previously established), we have found only for the patients over 60 years old a statistically significant difference. We have obtained a calculated value: $\chi^2(2) = 8.115$, $p=0.017$. This value signifies that patients over the age of 60 years old have more chances to be not for the first time in the laboratory, and, also, more chances that when arriving to the laboratory, patients' diagnoses were previously established (tab. VII).

TABLE VI

Analysis of age criterion (within item 20) and the first time in the laboratory (item 1)

		Age (years)							Total
		1-10	10-20	20-30	30-40	40-50	50-60	Over 60	
Item 1	Yes	3	2	1	10	6	31	75	128
	No	3	2	1	2	18	30	36	92
Total		6	4	2	12	24	61	111	220

TABLE VII

Analysis of the first time presence (item 1) with previously established diagnosis (item 5) for patients over 60 years old (within item 20)

		Item 5			Total
		Yes	No	I don't know this	
Item 1	Yes	53	11	11	75
	No	34	1	1	36
Total		87	12	12	111

We analyzed the measured variables from item 5 (previously established diagnosis) and item 3 (frequency of performing a scintigraphy) with age criterion. We have found that for patients belonging to age category 50-60 years old, there were significant differences, $\chi 2\ (2)=17.322$, $p=0.008$. The meaning of this value is that regardless of patients' gender those aged between 50 and 60 years old and previously diagnosed, have a higher probability to perform a scintigraphy at least once a year (tab. VIII).

TABLE VIII

Analysis of previously established diagnosis criterion (item 5) and frequency of scintigraphies (item 3) for patients aged 50-60 years old

		Item 5			Total
		Yes	No	I don't know this	
Item 3	Once a year	21	1	2	24
	Twice a year	5	0	0	5
	More than twice a year	0	1	0	1
	It is not the case	23	2	6	31
Total		49	4	8	61

Education level criterion

Analogue analysis for square chi criteria related to patients education level applied to item 1, showed no evidence of significant statistical differences, obtaining a value $\chi^2(4)=5.471$, $p=0.242$. Due to the fact that we did not obtain statistically

significant scores, these are evidences that access to this imaging exploration opportunity involves no social rank categories. On the contrary, educational and economical factors are not barriers to access at the latest medical investigation methods from public health system. From the education level point of view in relation with all the other items, the data we have acquired were not statistically significant. That is why we consider the principle of egalitarianism from this perspective can be reconsidered and there is a justice in the distribution of health care resources.

CONCLUSIONS

This study shows that the gender criterion played an important role in the performing scintigraphy for the first time. Unlike female patients, for the male patients, it is highly probable that they are for the first time in a Laboratory of Nuclear Medicine. The frequency of performing scintigraphy is increasing if you are a female patient than if you are a male patient.

Analyzing the frequencies for the measurable variables it results that, for female patients to whom the diagnosis were previously established, there is a higher probability that they are not in the laboratory for the first time, so, they have performed such a test before. If the diagnosis is already known, female patients, with a much more significant probability, are explored by scintigraphy at least once a year.

It has also been found that age criterion plays an important role in the scintigraphy investigations for all the patients. The first visit (we mean the first scintigraphy) being significantly represented in the category 40-50 years old, whilst for the patients aged over 60, probably they are not for the first time in the Laboratory of Nuclear Medicine.

For the patients with a previously established diagnosis with age over 60, there is a statistical significance that they are not experiencing a scintigraphy for the first time.

No matter the gender criterion, for the patients aged between 50 to 60 years old, with the diagnosis previously established before their arrival in the laboratory, there is a higher probability, with statistical significance, that they were explored at least once by scintigraphy.

Due to the fact that for the persons explored by scintigraphy there are not significant differences in connection with the education degree, we can conclude that access to that medical investigation is not depending on the socio-economic status of the patient and there are enough proofs that there is justice in the distribution of health care resources.

COMPARATIVE EVALUATION OF SERUM C-REACTIVE PROTEIN LEVELS IN CHRONIC AND AGGRESSIVE PERIODONTITIS PATIENTS AND ASSOCIATION WITH PERIODONTAL DISEASE SEVERITY

C-reactive protein (CRP) is an acute-phase reactant and has been proved to be a significant predictor of future cardiovascular events. Recent studies have demonstrated a correlation between periodontitis and elevated C-reactive protein levels. Most of the studies have focused on chronic periodontitis and very few studies are done in patients with aggressive periodontitis. The aim of a study realized by a group of indian researchers was to determine and to compare the relative levels of serum CRP in aggressive and chronic periodontitis patients. A total of 75 systemically healthy subjects were divided into three groups: group I (non-periodontitis subjects); group II (chronic generalized periodontitis patients) and group III (generalized aggressive periodontitis patients). All participants were subjected to quantitative C-reactive protein analysis using enzyme-linked immunosorbent assay. Mean CRP levels were significantly greater in both group II and III as compared to group I and group III having greater level than group II. CRP levels positively correlated with the amount of periodontal destruction as measured by probing depth and clinical attachment loss. The study indicates a positive correlation between C-reactive protein and periodontal disease severity with particular concern in younger individuals that could be a possible underlying pathway in the association between periodontal disease and the observed higher risk for cardiovascular disease in periodontitis patients (Goyal L, Bey A, Gupta ND, Sharma VK. Comparative evaluation of serum C-reactive protein levels in chronic and aggressive periodontitis patients and association with periodontal disease severity. *Contemp Clin Dent*, 2014; 5 (4): 484-488).

EPIDEMIOLOGICAL STUDY OF METABOLIC SYNDROME AND RISK OF DIABETES MELLITUS IN A RURAL FAMILY MEDICINE PRACTICE IN BACAU COUNTY (Abstract) **Aim:** This descriptive epidemiological study included 615 subjects investigated by their family doctor in the interval October 2011- August 2012. **Material and Methods:** Patients were selected according to 2012 IDF diagnostic criteria resulting 304 patients. **Results:** There was a Gaussian distribution of waist circumference (WC) with a maximum in age-group 70-80 years (46.3%), followed by age- groups 50-60 years (37.8%) and 60-70 years (41.6%). Waist circumference measurement showed an average of 100.76+/-11.59 cm, ranges 72 cm - 134 cm, without statistical significance. Mean body mass index (BMI) was 28.25+/-4.72 kg/m^2 *vs.* 27.79+/-4.48 kg/m^2. The difference is statistically significant (p=0.05). Considering categorical the patients with hypertension (AHT) according to the definition, we found that only 7 cases did not have AHT (4.4%) as compared to a prevalence of AHT of 13.7% in the MS (metabolic syndrome) group. Mean serum triglyceride level was 123.11+/-68.55mg/dl *versus* 113.75+/-65.62mg/dl in the MS group, significantly higher (p<0.003). Mean HDL cholesterol was 57.58+/-17.11mg/dl *versus* 58.54+/-15.02mg/dl, statistically significant difference (p<0.05). **Conclusions:** The prevalence of glucoregulation disorders is higher in the MS group. Proportional relationships were found between BMI, WC, and SBP and high blood glucose. Comparison of blood glucose levels at baseline and at 1 year follow up showed significant differences. **Keywords**: METABOLIC SYNDROME, DIABETES MELLITUS, EPIDEMIOLOGY, SCREENING.

Diabetes mellitus type 2 is associated with metabolic and biochemical abnormalities, including hyperglycemia, hypertension, inflammation, atherogenic dyslipidemia, endothelial dysfunction and inhibition of fibrinolysis, each of these anomalies promoting atherosclerosis and cardiovascular disease (1, 2, 3).

MATERIALS AND METHODS

This epidemiological study was conducted in Pancesti village, Bacau County, with a population of 1463 persons aged 0-89 years, having or not having health insurance, regis-

tered with the family doctors. The group of interest to our study, the adult population aged 35-89 years, accounted for 969 individuals (66.23% of the population), of which 542 (55.93%) women and 427 (44.07%) men. Of these, 615 subjects had high waist circumference (WC) according to IDF criteria (≥ 80 cm in women and ≥ 94 cm in men) (tab.I).

TABLE I
Distribution of subjects by study groups

<table>
<tr><td rowspan="4">Total population: 1463</td><td rowspan="4">35-90 years: 969</td><td rowspan="4">IDF, criteria, WC:615</td><td rowspan="2">Women: 422</td><td rowspan="2">68.62%</td><td>MS + 222</td><td>36.10%</td></tr>
<tr><td>MS – 200</td><td>32.52%</td></tr>
<tr><td rowspan="2">Men:193</td><td rowspan="2">31.38%</td><td>MS + 108</td><td>17.56%</td></tr>
<tr><td>MS – 85</td><td>13.82%</td></tr>
</table>

This epidemiological study was descriptive, transversal and included 615 subjects investigated by their family doctor in the interval October 2011-August 2012. All subjects underwent a complete history and physical examination, with measurement of waist circumference (soft tape) and arterial blood pressure (ABP). A second visit was scheduled for fasting night laboratory tests: blood glucose level, triglycerides, HDL-cholesterol, liver and kidney function tests. Then, more test were performed, including total serum cholesterol and LDL-cholesterol, to assess overall cardiovascular risk. To detect another co-existing cardiovascular risk factor the subjects were questioned directly about: alcohol use (yes or no and estimated amount), physical exercise (yes or no), and education level (less than 8 grades, or high school/higher education), family history of diabetes and hypertension (yes or no) in at least one first-degree relative, smoking (yes or no), economic or social stress. According to 2012 IDF criteria 615 subjects had a waist circumference ≥ 80 cm in women and ≥ 94 cm in men (63.47% of the total of 969 adult population). The patients were divided into two groups according to the presence/absence of the metabolic syndrome (MS): group I, consisting of 330 patients with overt metabolic syndrome (increased waist circumference and at least two other components of the metabolic syndrome) and group II consisting of 285 subjects without overt metabolic syndrome, but having one or two components of the metabolic syndrome (tab. I). Of all analyzed subjects we selected the 330 patients with metabolic syndrome. Of these, some died or left the village; thus, the study group included 304 patients (tab. II).

Of the 304 patients we selected a group of patients with fasting glucose > 100 mg/dl, the threshold at which it is a cardiovascular risk factor. So we further studied a group consisting of 204 cases. Of these, 132 were women (64.7%) and 72 men (35.5%) (tab.III). When these data were reported to the studied population and to those with overt metabolic syndrome the following *incidence data* were obtained: total 1462 subjects => incidence 13.9%, and 615 MS cases - incidence 33.1%. For further clinical-biological investigations of the patients with glucoregulation disorders a total of 159 cases were selected, the other patients refusing to continue this study or

were already known with diabetes and were on treatment. This patient group consisted of 101 women (63.5%) and 48 men (36.5%). The mean age of the study group was 68.23 + / -9.18 years, ranges 37 – 87 years. In this group, 11 cases (6.9%) had blood glucose levels above 126 mg/dl, which is they had diabetes mellitus.

RESULTS

Age distribution of glucoregulation disorders. Age distribution of impaired fasting glucose patients showed a Gaussian distribution with a maximum among age group 70-80 years (46.3%), followed by age groups 50-60 years (37.8%) and 60-70 years (41.6%). In this group the average waist circumference was 100.76+/-11.59cm, ranges 72 cm -134 cm, compared to an average of 99.36 +/-10.27 cm in the MS group (615 cases), not statistically significant difference. Categorical comparison of waist circumference-related data (WC=abdominal obesity, F> 80 and B> 94 cm) showed that most patients (98.7%) presented abdominal obesity. Basically, only two cases did not meet these criteria. Obesity measured by body mass index (BMI) gave an average of 28.25 +/-4.72 kg/m², with high variance data, 22.31 kg/m^2, which proves the dispersion of data. In the MS group (615 cases), the average was 27.79 +/-4.48 kg/m². The difference is statistically significant (p = 0.05). The obtained percentages reveal a significantly higher (p=0.087) proportion of diabetes mellitus (DM) among the obese group compared to the group with normal BMI. When considering categorical the patients with AHT according to the definition, we found that only 7 cases did not have AHT (4.4%) compared to a 13.7% prevalence of hypertension in the MS group. Gender distribution was balanced: 95%

females and 96.6% males, with no significant differences. In the MS group AHT was more common in males, 92.2%. Mean triglyceride level was 123.11 +/- 68.55 mg/dl *versus* 113.75+/- 65.62 mg/dl in the MS group, being significantly higher (p<0003). Mean HDL cholesterol was 57.58+/-17.11 mg/dl *versus* 58.54+/-15.02 mg/dl, with statistical significance (p<0.05). Descriptively, in the group of 159 patients the measurement of serum cholesterol levels showed a moderately increased mean value, 214.06 =+/- 49.92 mg/dl, the data being very scattered (104 to 347 mg/dl). The same was found for LDL cholesterol. The mean was 115.58+/- 36.33 mg/dl. Thirty-five (22%) patients were smokers, and 67 (42.1%) were alcohol users. One hundred and forty patients (88.1%) had an education higher than middle school. Ischemic heart disease and stroke were present in 33.3% and 3.8% of cases, respectively.

Association of metabolic syndrome elements revealed a high prevalence of the association between abdominal obesity (increased WC), hypertension and BMI over 25 kg/m (tab. IV).

When comparing the 2 groups: with or without blood glucose ≥ 100mg/dl, 204 cases, *vs.* the group of 107 cases we found no statistically significant differences in cholesterol level. In the group with blood glucose above or equal to 100 mg/dl WC was statistically significantly higher than in the group with blood glucose below 100 mg/d. The mean was over 3 cm and the median 2 cm higher, unlike BMI where differences were insignificant (fig. 1, 2).

No statistical difference was found between SBP and DBP (fig. 3, 4).

No statistical differences in cholesterol and LDL cholesterol levels were found between the two groups (fig. 5, 6).

Triglycerides were statistically significantly higher in the group with blood glucose <100 mg/dl, and HDL cholesterol was significantly lower in the group with blood glucose <100 mg/dl (fig. 7, 8).

TABLE IV

Association of metabolic syndrome elements

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid		1	.6	.6	.6
	AHT/BMI≥25	1	.6	.6	1.3
	WC/ low HDL / BMI≥25	1	.6	.6	1.9
	WC / AHT	30	18.9	18.9	20.8
	WC / AHT / low HDL	4	2.5	2.5	23.3
	WC / AHT / low HDL / BMI≥25	21	13.2	13.2	36.5
	WC / AHT / BMI≥25	58	36.5	36.5	73.0
	WC / AHT / Triglycerides >=150	7	4.4	4.4	77.4
	WC / AHT / Triglycerides>=150 / low HDL / BMI≥25	12	7.5	7.5	84.9
	WC / AHT / Triglycerides>=150 / BMI≥25	19	11.9	11.9	96.9
	WC / BMI≥25	4	2.5	2.5	99.4
	CA / Triglycerides>=150	1	.6	.6	100.0
	Total	159	100.0	100.0	

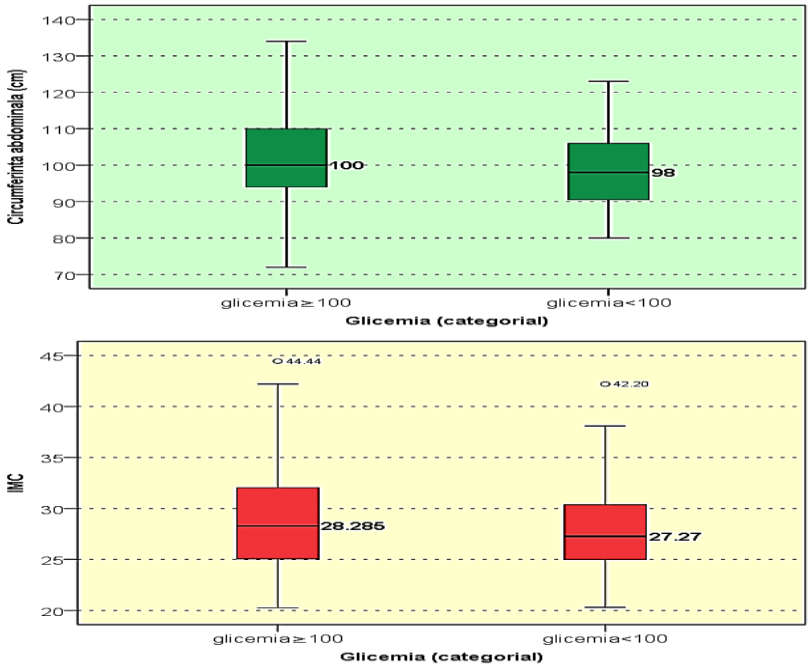

Fig. 1, 2. Comparisson of WC and BMI with blood glucose leves

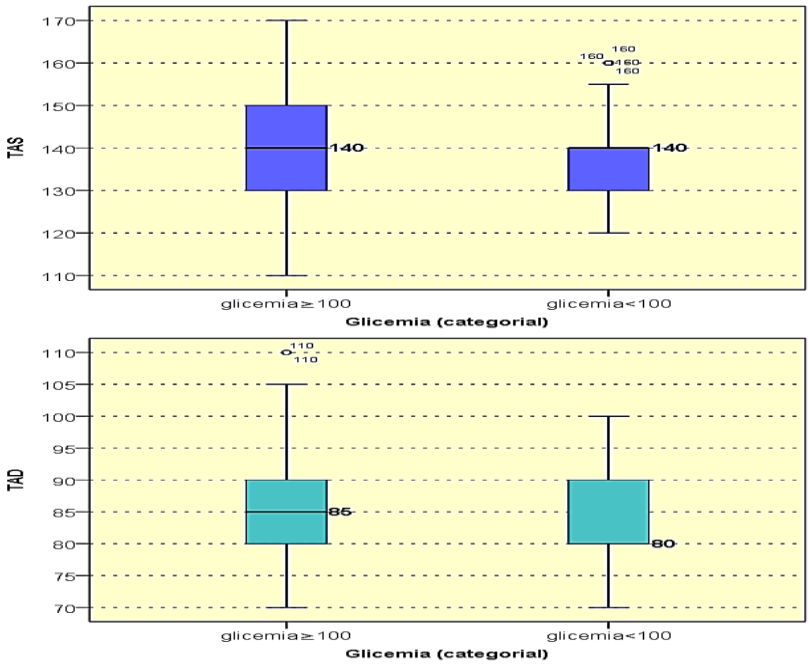
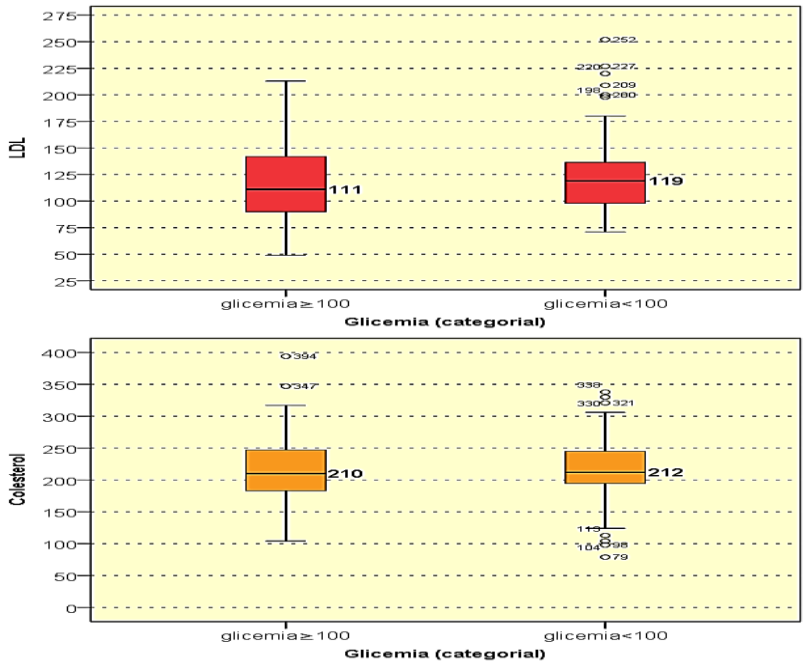
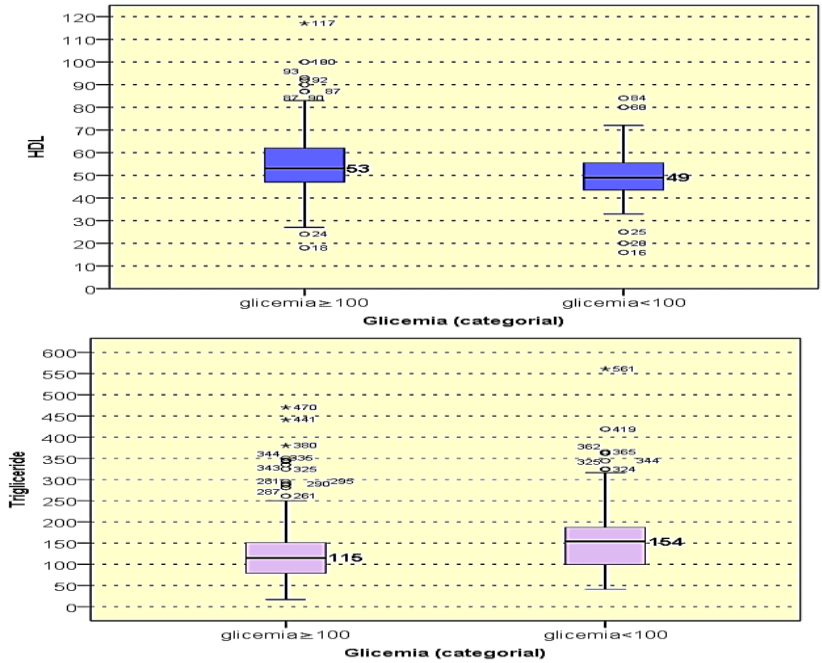


Figs. 3,4. Comparison of SBP and DBP with blood glucose levels



Figs. 5,6. Comparison of LDL cholesterol and total cholesterol with blood glucose levels



Figs. 7,8. Comparison of HDL cholesterol and triglycerides with blood glucose levels

1) *Regression analysis*. In the group of 311 patients we determined the relationship between the variable *blood glucose* and the possible predictors: BMI, WC, age, SBP, DBP, cholesterol, triglycerides, HDL cholesterol. Using multiple linear regressions we obtained significance for WC, SBP and DBP. The coefficient of determination was 0.062 showing that only 6.2% of the variation in glucose levels can be explained by the model. Such a small percentage is unacceptable.

2) *Analysis of associations by the correlation method*. Our data do not show a normal distribution of blood glucose levels. The correlation coefficient can be calculated by using Pearson (parametric) or Spearman (nonparametric) methods (tab. V).

TABLE V

Analysis of associations by correlation method

Blood glucose	**BMI**	**Waist circumference**	**Age**	**SBP**	**DBP**	**Cholesterol**	**Triglycerides**	**HDL**
Pearson Correlation	.159**	.162**	.014	.156**	.000	-.052	-.058	.005
Sig. (2-tailed)	.005	.004	.801	.006	.993	.365	.307	.933
N	311	311	311	311	311	311	311	311
Blood glucose	BMI	Waist circumference	Age	SBP	DBP	Cholesterol	Triglycerides	HDL
Spearman's Correlation	.160**	.172**	.014	.147**	-.002	-.057	-.127*	.109
Sig. (2-tailed)	.005	.002	.804	.009	.972	.317	.025	.056
N	311	311	311	311	311	311	311	311

** Correlation is significant at the 0.01 level (2-tailed).

*. Correlation is significant at the 0.05 level (2-tailed)

Using the correlation method we obtained directly proportional relationships for BMI, WC and SBP. The other variables showed no statistical significance, meaning a lack of influence on blood glucose according to our data.

Comparison of fasting glucose at baseline and after one year of clinical and biological follow-up showed significant differences: the mean baseline blood glucose level was statistically significantly higher than that measured after 1 year of clinical and biological follow-up: 110.38+/-12.67 mg/dl *versus* 104.2+/-12.58 mg/dl ($p < 0.001$). We can say that there was an average drop by approximately 6 units between baseline and 1-year blood glucose levels.

DISCUSSION

The prevalence of diabetes mellitus (DM) varies significantly depending on the population studied, age, sex, socioeconomic status and lifestyle. According to IDF/WHO, the prevalence of DM will reach 9% in 2025. Type 2 DM accounts for 80-90% of all DM cases and is more common in overweight or obese persons. More than half of the patients have one or more chronic complications of DM at the time of diagnosis (5). Patients with type 2 DM have a 2-4 times higher risk for cardiovas-

cular disease (CVD) than nondiabetic population (6). CVD is a common complication of DM being responsible for 80% of deaths in people with diabetes (7). Selecting cases with glucoregulation disorders aimed at emphasizing the importance of active screening of impaired fasting glucose for the early diagnosis of DM and implicitly for initiating preventive measures and appropriate therapy. We found statistically significant differences in terms of both anthropometric parameters and biological elements compared to extended group presenting only increased WC. Another important finding was the statistically significant improvement of fasting blood glucose control after 1 year.

CONCLUSIONS

The difference is statistically significant of BMI ($p = 0.05$). In the MS group AHT was prevalent in males, 92.2%. Mean serum triglyceride level was 123.11+/-68.55 mg/dl *versus* 113.75+/-65.62 mg/dl in the MS group, significantly higher ($p < 0003$). Mean HDL cholesterol was 57.58+/-17.11 mg/dl *versus* 58.54+/-15.02 mg/dl, statistically significant difference ($p < 0.05$). The proportion of glucoregulation disorders was higher in the MS group. According to correlation method we obtained directly proportional relationship for BMI, WC, and high blood glucose. Comparison of fasting glucose levels at baseline and at 1 year follow-up revealed significant differences.

3. Discipline of Primary Health Care and Epidemiology

USING ARCGIS SOFTWARE IN THE PRE-HOSPITAL EMERGENCY MEDICAL SYSTEM (Abstract): **Aim**. To measure the accessibility to healtcare services in order to reveal their quality and to improve the overall coverage, continuity and other features. **Material and methods**. We used the software ESRI Arc GIS 9.3, the Network Analyst function and data provided by Ambulance Service of Iasi (A.S.I.) with emergencies statistics for the first four months of 2012, processed by Microsoft Office Excel 2010. As examples, we chose "St. Maria" Children's Emergency Hospital and "St. Spiridon" Emergency Hospital. **Results**. ArcGIS Network Analyst finds the best route to get from one location to another or a route that includes multiple locations. Each route is characterized by three stops. The starting point is always the office of Ambulance Service of Iasi (A.S.I.), a second stop at the case address and the third to the hospital unit chosen according to the patient's diagnosis and age. Spatial distribution of emergency cases for the first four months of 2012 in these two examples is one unequable, with higher concentrations in districts located in two areas of the city. **Conclusions**. The presented examples highlight the poor coverage of healthcare services for the population of Iasi, Romania, especially the South-West area and its vulnerability in situations of emergency. Implementing such a broad project would lead to more complex analyses that would improve the situation of pre-hospital emergency medical services, with final goal to deserve the population, improve the quality of healthcare and develop the interdisciplinary relationships. **Keywords**: HEALTCARE SERVICES, EUROBAROMETER, ROUTING, SERVICE AREA

Accessibility to health care services is conditioned by the real availability of the facilities offered by the healthcare system and real demand for health. Within the European Union, the access to healthcare services is officially decided at the legislative level, representing a fundamental right of the individual to receive medical treatment and prevention.

Access to healthcare systems is a criterion that reveals that system is well organized and optimally conducted, among other criteria: overall coverage, continuity, the possibility to choose the healthcare provider, rehabilitation, a.s.o. (1).

Measuring access to healthcare services represents an element of equity and a right of the customer who pay taxes to the provider, but the quality of services as well. In order to measure access to healthcare, the

Eurobarometer uses indicators such as: the distance to the nearest hospital (under 20 minutes, between 20 and 50 minutes, an hour or more); accessibility by foot to the nearest hospital (walking).

In the European Union, rapid access (under 20 minutes) to the hospital is not universal. Between 38 and 50% of the population has access to the hospital so quickly. It must be taken into account that small countries have an advantage, because the distance rural-urban is more reduced, such as The Netherlands or Estonia. Meanwhile, large countries such as France or Poland, recorded better access than Romania (2).

MATERIAL AND METHODS

In order to initiate the study, we used the software ESRI Arc GIS 9.3, the Network Analyst function and data provided by Ambulance Service of Iasi (A.S.I.) with emergencies statistics for the first four months of 2012, processed by Microsoft Office Excel 2010.

GIS is a software environment for spatial analysis that has, as main feature, the representation of the real world or geographical space as layers or thematic maps (3). ArcGIS Network Analyst provides network-based spatial analysis such as routing, travel directions, the nearest emergency unit (closest facility) and service or coverage area (service area). It is built as a own subsystem and uses an advanced network model (Network Data Model) that allows the use of data sets with multiple attributes (4).

RESULTS AND DISCUSSION

Route

ArcGIS Network Analyst finds the best route to get from one location to another or a route that includes multiple locations. If we have more inside route stops, displaying the best route will be based on the order of locations specified by the user. ArcGIS Network Analyst will display the best routing for that path. Whether it is about finding a simple path between two points or a path with a sequence of locations, people usually try to find the best route. But "the best route" can assume different things to different situations.

The best route may be the fastest, shortest or most scenic path, depending on the chosen impedance. *Impedance* is the barrier or the limit set by the user. If the chosen barrier is time, then the best route will be one of the fastest routes. Therefore, the best route may be defined as the path with the lowest impedance. Any valid attribute can be used as impedance to determine the best route (5).

Accessibility refers to the facility with which you can get to a location. In ArcGIS Network Analyst, accessibility can be measured in terms of travel time, distance or any other impedance network (6). Each route is characterized by three stops. The starting point is always the office of Ambulance Service of Iasi (A.S.I.), a second stop at the case address and the third to the hospital unit chosen according to the patient's diagnosis and age. The route display is performed in a few seconds, after careful selection of these three points.

Description of routes

- First route (yellow route), departing from the A.S.I. to 64 Pacurari Street, for a major emergency - diagnosis: seizures in a 26-year female patient, transported by a type B ambulance to Clinical Hospital of Neurology.
- Route two (blue route), starting from the A.S.I. to 5 Minerva Street, for a major emergency – diagnosis: broken membranes of a 35-year female patient, transported by a type A ambulance to "Cuza Voda" Hospi-

tal of Obstetrics and Gynecology.

- First route (purple route), departing from A.S.I to 6 Jelea Str., for a major emergency – diagnosis: attempted suicide of a 52-year male patient, transported by a type B ambulance to "St. Spiridon" University Emergency Hospital.
- First route (green route), departing from the A.S.I. to 10 Chimiei Blvd., for a major emergency – diagnosis: seizures in a 19-year male patient transported by a type C ambulance to Clinical Hospital of Neurosurgery (fig. 1).

Service areas

The Network Analyst may identify service areas around any location on a network. A service area is a region that encloses all accessible streets, representing the streets that are in the specified impedance area (7).

As examples, we chose “St. Maria” Children's Emergency Hospital and “St. Spiridon” Hospital. Spatial distribution of emergency cases for the first four months of 2012 in these two examples is one unequable, with higher concentrations in the districts of “Dacia”, “Alexandru cel Bun”, “CUG”. For “St. Maria” Hospital, the service area was performed compared to the emergencies cases in population age group under 18. It notes that it serves a small area of the surface of the city, which leads to solve the cases in a longer period of time, especially a small number of emergency cases. Districts that do not enclose in the service area (0-2000 meters) were located in the North-West and South-West of the city, such as districts of “Ticau”, “Copou” “Pacurari”, “Dacia”, “Galata”, “Nicolina”, and “CUG” (fig. 2).

Instead, for “St. Spiridon” Hospital, the service area covers the central area of the city, facilitating more rapid resolution of emergencies cases, due to a high accessibility to other districts. Districts that do not enclose in this service area is those of South-West and South-East (fig. 3). This representation was applied to emergency patients over 18 years old.

Nowadays, Public Health problems are much larger than the field of their application. Specialists depend on modern technologies such as GIS, and mapping of applications useful in their analyses. GIS leads to understanding and improving public health problems and improve quality of healthcare and increase accessibility.

Mapping and analysis solution consign to dispatchers and field workers vital information. It allows “911” centers use real data of incident to predict expected emergency calls. Mapping intelligence allows an ambulance to be put to a better location to reach an incident in the fastest time.

CONCLUSIONS

In this research, we have considered accurate exemplify of relationships between the access to healthcare services, the health of the population, and pre-hospital emergency medical services. The presented examples revealed the poor coverage of healthcare services for the population of Iasi, especially the South-West area and its vulnerability in situations of emergency.

Initially, we calculated the population accessibility to emergency care units from the City of Iasi, highlighting the fact that at this scale of analysis, we can correlate the centrality with the accessibility. Implementing such a broad project would lead to more complex analyses that would improve the situation of pre-hospital emergency medical services, with final goal to deserve the population, improve the quality of healthcare and develop the interdisciplinary relationships.

CALCIUM AND VITAMIN D SUPPLEMENTS AND CHOLESTEROL PROFILE

Vitamin D has multiples roles in the calcium metabolism, modulation of cell growth, immune function and reduction of inflammation. Many studies have linked low levels of the vitamin D with an increased risk of type 1 diabetes, various types of cancers (breast, colon, prostate, and ovaries), heart attacks, rheumatoid arthritis or multiple sclerosis. In a recent study, Schnatz and colleagues assessed influence of calcium and vitamin D supplements on cholesterol profile in postmenopausal women. The researchers administered a daily dose of 400 units of vitamin D and 1,000 milligrams of calcium and respectively placebo to a group of 576 postmenopausal women. They followed serum 25-hydroxyvitamin D3 (25OHD3) concentrations and lipid levels before and after calcium and vitamin D administration. The results showed a significantly increase of serum 25OHD3 concentrations for women who took the supplement (24.3 ng/mL) compared with placebo (18.2 ng/mL) and a 4.46-mg/dL mean decrease in low-density lipoprotein cholesterol. In addition, the supplement users had elevated levels of high-density lipoprotein cholesterol and lower levels of triglycerides. These results support the importance of an increased serum level of 25OHD3 for improving cholesterol profiles (Schnatz PF, Jiang X, Vila-Wright S et al. Calcium/vitamin D supplementation, serum 25-hydroxyvitamin D concentrations, and cholesterol profiles in the Women's Health Initiative calcium/vitamin D randomized trial. *Menopause*, 2014; 1 DOI: 10.1097/GME.0000000000000188).

STUDY OF DENTAL AND SKELETAL DISORDERS IN MONO- AND DIZYGOTIC TWINS (Abstract): The aim of this study was to analyze and to compare the dental and skeletal morphology of mono- and dizygotic twins (MZ and BZ). **Material and methods:** 10 sets of monozygotic (mean age: 18.5 years) and 10 sets of dizygotic (mean age: 19.7 years) twins were examined, cast analysis, ortopantomography and lateral cephalometric films were analyzed. **Results:** The upper frontal teeth dimension and shape is the same in 99.69% of MZ and 93.91% of the DZ twins. In MZ twins we found different values for transversal arch width and upper intercanine distance. The dental malpositions were different in the DZ sets, especially in tranversal and sagital plan. The same differences were seen in the arch forms. The skeletal pattern was also different between the components of DZ twins. The cephalometric values showed slight differences of the interincisal angle both in MZ and DZ twins. **Conclusions:** Genetically influenced patterns can be explained by the results of our study.
Keywords: MOMOZYGOTIC TWINS, DIZYGOTIC TWINS, MALOCCLUSIONS

A twin is one of two offspring produced in the same pregnancy. Twins can either be monozygotic ("identical"), meaning that they develop from one zygote that splits and forms two embryos, or dizygotic ("fraternal") meaning that they develop from two eggs, each fertilized by separate sperm cells.

The twin method is one of the most effective methods available for investigating genetically determined variables in orthodontics, as well as in other medical fields, depending on the variance in the shape and the size of skull and teeth, both on genetic and environmental influences. In the meantime, the results of these studies cannot be always transposed to the singleton population, unless extensive analysis of the parents and nutritional, functional habits is made (1).

The purpose of this study was to analyze the dental and skeletal pattern, the type of malocclusion in the components of

MZ and DZ sets.10 MZ (5 boys and 5 girls, mean age: 18.5 years) and 10 DZ (same sex, 7 boys and 3 girls, mean age: 19.7 years) consisted the analyzed sample. In each case dental casts, panoramic X-ray and lateral cefalograms were studied.

At the dental cast analysis we examined every tooth's position in all of the three planes, the position of the frontal and lateral dental groups, the shape of the arches, the symmetry of the arches (symmetroscopy), the transversal, sagital and vertical development of the dental arches (Pont and Korkhaus index, intercanine width), we studied the static occlusion in all of the three planes (2, 3, 4).

On the panoramic X-rays we followed the presence of all teeth, the shape and the development stage of the roots, agenesis or supranumerary teeth (fig. 1).

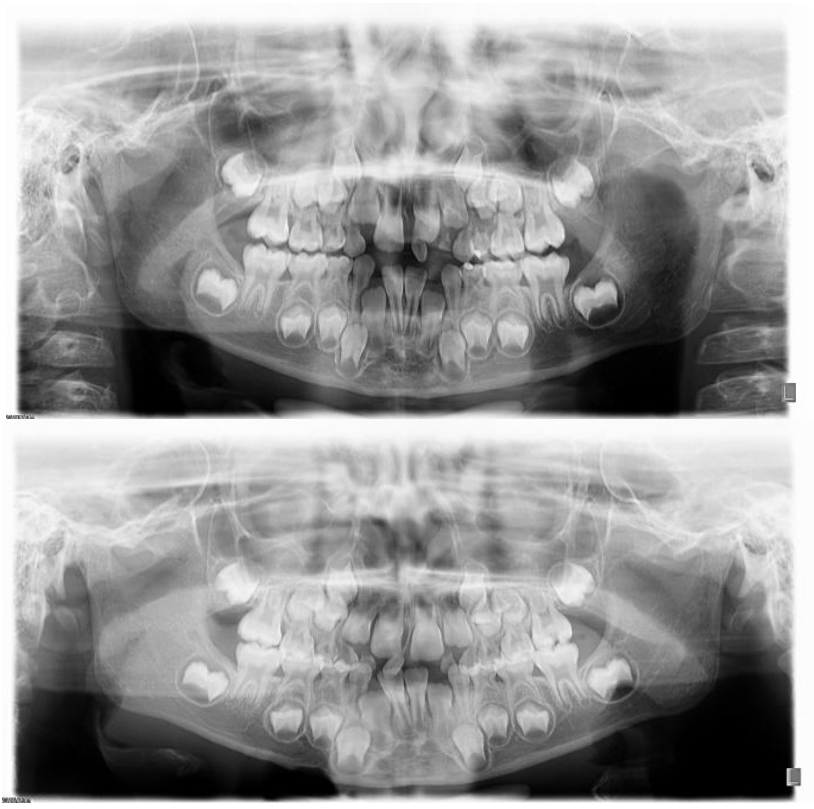

Fig. 1. H.K. and H.L., MZ twins (8 years) – simetrical supranumerary teeth

The lateral cefalogram were interpretated using the Tweed analysis technique. Cefalograms were traced according the mentioned technique with different colored pencils in case of a twin set. Frankfort-mandibular incisal angle (FMIA), Frankfort-mandibular plane angle (FMA), incisor-mandibular plane angle (IMPA), sella-nasion-point A (SNA), sella-nasion-point B (SNB), point A-nasion-point B (ANB), sella-gnation-Frankfort (SGn-F) and interincisal angles were measured. We superimposed each pair of cefalogram on sella-nasion plane in S (6,7) (fig. 2).

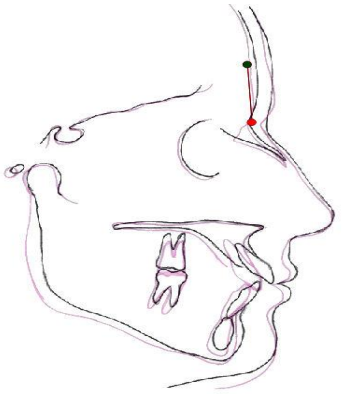

Fig. 2. Superimposition of lateral cefalograms of a set of MZ twins

RESULTS

The upper anterior teeth dimension and shape were similar in 99.69% of MZ and 93.91% of DZ sets. Upper arch transversal width was found different in MZ sets, especially in intermolar region. Intercanine width was slightly dissimilar in the upper arch in the MZ sets (fig. 3, 4). We found difference in the static occlusion analysis, 4 sets of DZ twins presented different sagital relationship in molar and canine region.

As far as dental malpositions are concerned, only 50% of both MZ and DZ sets presented symmetrical dental positions, in 5 MZ twins we found a so called "mirror image": left ectopic or retained canine in one, right ectopic or retained canine in the other component of the twin set or different way of mandibular shift at the two components (fig. 5).

In cefalometric analysis we found slight difference in the IMPA and interincisal angle both in MZ and DZ sets.

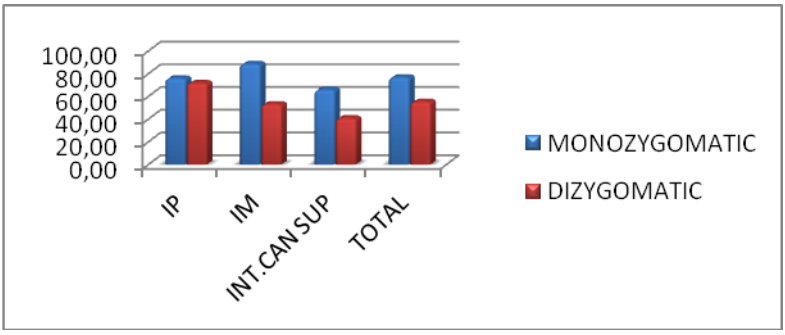

Fig. 3. Comparison of transversal arch width measurements in the upper arch

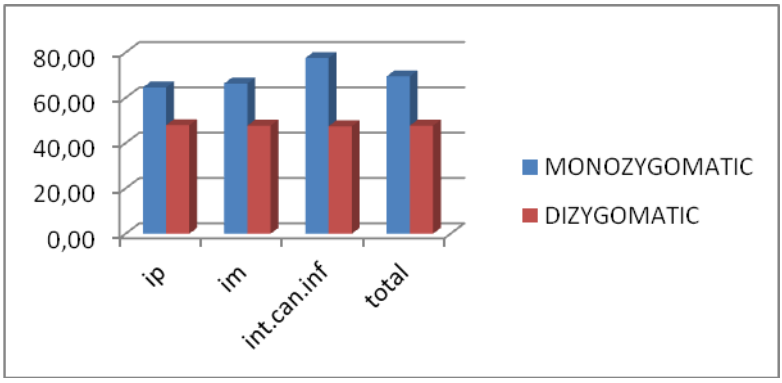

Fig. 4. Comparison of transversal arch width measurements in the lower arch

Fig. 5. Ectopic canines in mirror image in a MZ twin set

DISCUSSION

Since Francis Galton's classic paper (8) of 1875, twin studies have been viewed as an ideal way to evaluate the interaction between genetic (nature) and environmental (nurture) influences on a particular phenotype, including dentofacial variations (9). Biologically, twinning results from a single fertilized ovum; so MZ twins are identical genetically. The chance that both MZ twins would express the same uncommon abnormality or condition as a random happening is highly unlikely (10).

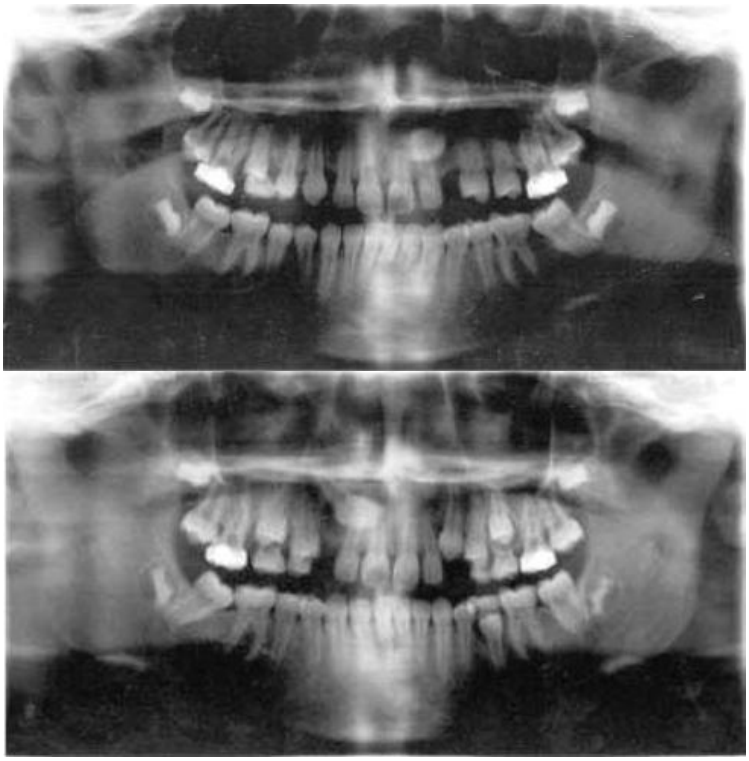

Fig. 6. Retained canines in mirror image in a MZ twin pair (Cs.B., Cs.N - 10 years)

The study of craniofacial relationships in twins has provided much useful information concerning the role of heredity in malocclusion. The procedure is based on the underlying principle that observed differences within a pair of monozygotic twins (whose genotype is identical) are due to environment and that differences within a pair of dizygotic twins (who share 50 per cent of their total gene complement) are due to both environment and genotype. A comparison of the observed within-pair differences for twins in the two categories should provide a measure of the degree to which monozygotic twins are more alike than dizygotic twins. The larger this differences between the two twin categories, the greater the genetic effect on variability of the trait. This model implies that zygosity is accurately determined and that environmental effects are equal in the two twin categories. At the present time, accurate zygosity classification is seldom a problem due to the ability to identify the large number of available polymorphic blood group and enzyme markers. (11).

The dentitions and faces of twins provide a good opportunity to study the fascinating phenomenon of mirror-imaging, in which one twin mirrors the other for one or more features (fig. 6). As Mosey (11) has pointed out, 'the key to the determination of the etiology of malocclusion, and its treatability, lies in the ability to differentiate the effect of genes and environment on the craniofacial skeleton in a particular individual'. Twin studies have confirmed that genetic influences contribute to variation in occlusal traits to varying degrees, with tooth size and arch shape displaying relatively high heritability, whereas heritability estimates for inter-arch variables such as overbite and over jet are considerably lower (12)

However, these findings have not led to major changes in the clinical management of malocclusions (13).

NEWS

OSTEOPOROSIS AND PERIODONTAL DISEASE

Osteoporosis (OP) is a systemic skeletal disease characterized by low bone mass and micro architectural deterioration of bone tissue, with a consequent increase in fragility and susceptibility to fracture of bones. In the past, OP was considered a physiological process associated with ageing, but today it is recognized as a multifactorial chronic systemic disease. OP may affect also the jawbones, whose structure may be impaired by other conditions resulting in bone loss. One of these, is periodontitis (PD), a chronic infection-mediated condition modulated by different genetic and environmental factors, characterized, in advanced forms, by loss of the soft tissue attachment to teeth and resorption of alveolar bone . PD is the prototype of a low grade local infection (bacteria of the oral plaque) associated with local (within the periodontal tissues) immune-inflammatory response causing periodontal tissue damages/destruction and a mild individual systemic inflammatory response contributing to the global inflammatory burden and to its related dangerous effects. It might be expected that the alveolar bone destruction seen in periodontitis could be magnified in the presence of generalized skeletal disturbances such as OP. Thus, a relationship between OP and PD might be probable, but further prospective and sensitive studies are required in order to provide definitive evidence. By now, available data underline the primary importance of dentists in the early diagnosis of OP, because of the opportunity to assess the health of the entire skeleton of the patient through dental radiography. This is of considerable clinical interest, considering that such dental radiological investigations are routinely performed for diagnosis and treatment of dental and periodontal diseases, which are particularly frequent in the same population affected by OP. This may also provide clues for new preventive strategies and/or early therapeutic approach resulting in a potential reduction of bone resorption and contributing to maintain bone biomechanical characteristics (e.g. architecture, remodelling, quality of matrix collagen and its mineralization). In fact, the prevention of OP is the most rational and modern approach to defeat the disease, and early diagnosis is one of the foundations of modern medicine; the dentist seems to have an important role not only in monitoring/maintaining the oral and periodontal health and its relationships with systemic health, including OP, but also in drafting diagnostic/therapeutic paths and participating in counselling for OP in collaboration with general practioners and other specialists (Rosario Guiglia, Olga Di-Fede, Lucio Lo-Russo. Osteoporosis, jawbones and periodontal disease. *Med Oral Patol Oral Cir Bucal*. 2013 Jan 1;18 (1):e93-9).

IN VIVO BIOCOMPATIBILITY EVALUATION OF SOME *BIDENS TRIPARTITA* EXTRACTS IN MICE (Abstract): Adaptogens represent a class of herbs frequently used as a unique and natural alternative medicine and herbal remedy for treating the many forms of stress and different other pathological conditions. *Bidens tripartite,* a flowering plant from the genus Bidens, family *Compositae*, subfamily *Asteroideae* was widely used in traditional medicine for its antiseptic, anti-inflammatory, antioxidant, astringent, diuretic, febrifuge, narcotic and sedative effects. Phytochemical analysis of this plant has revealed the presence of flavonoids, xanthophylls, volatile oil, acetylene and polyacetylene, sterols, aurones, chalcones, caffeine and tannins. **Aim:** The *in vivo* biocompatibility evaluation of two extracts from *Bidens tripartita* plant in rats. **Material and methods:** The vegetable product used for the study was obtained after maceration and extraction in alcohol. Flower powder was dissolved in absolute chloroform, re-extracted and filtered. After a complete dryness the product was extracted by the addition of ethanol then evaporated. The chemical composition of the extracts was determined. The administered dose of *Bidens tripartita* retained was 1/20 of lethal dose 50 (LD50). The experiment was carried out on white male Wistar rats (200-250g) divided into 3 groups of 7 animals each treated intraperitoneally as follows: Group I (Control): distilled water 0.1ml/10g weight; Group II (coded BT-alcoholic): 200mg/kbw alcoholic *Bidens tripartita* extract; Group III (coded BT-aqueous): 250mg/kbw aqueous *Bidens tripartita* extract. The biocompatibility properties of alcoholic and aqueous extracts from *Bidens tritartita* were studied by assessing their effects on blood count and serum biochemical tests. The following immune parameters: phagocytic capacity of peripheral neutrophils (NBT test) and serum complement activity were also evaluated. The data were presented as +/- SD and significance was tested by SPSS for Windows version 13.0 and ANOVA method. Experimental protocol was implemented according to the recommendations of the University Committee for Research and Ethical Issues and guidelines of IASP Committee for Research and Ethical Issue. **Results**: Laboratory analysis did not show significant differences on leucocyte formula (GOT, GPT and LDH) or immune parameters (phagocytic capacity of peripheral neutrophils and serum complement activity) between alcoholic and aqueous *B. tripartita* extracts and distilled water, elements suggesting a good *in vivo* biocompatibility. **Conclusions**: In our experimental conditions, the alcoholic extract and aqueous extract from *B. tripartita* determined similar immune responses as distilled water following intraperitoneal administration in rats, indicative of good in vivo biocompatibility. **Keywords**: BIDENS TRIPARTITA, IN VIVO BIOCOMPATIBILITY, RATS.

Medicinal plants and herbs contain substances known to modern and ancient civilizations for their properties.

The word and concept of an adaptogen is a relatively new way of describing a type of remedy commonly found in traditional medicine (1, 2).

Adaptogens represent a class of herbs frequently used as a unique and natural alternative medicine and herbal remedy for treating the many forms of stress and different other pathological conditions (3, 4).

An adaptogen has non-specific activity and acts by increasing resistance of the body to a various adverse biological, chemical, and physical factors (5, 6).

The active substances present in these plants have the ability to balance endocrine hormones and the immune system, and they help the body to maintain optimal homeostasis and tend to help regulate or normalize organ and system function within the organism (7). They modulate the body response to stress (physical, environmental, or emotional) and help regulate the interrelations between endocrine, immune, and nervous systems (8).

Literature data show that around 80 percent of the world population largely depends on traditional natural medicine. Most of these natural remedies are based on medicinal plants and herbs, with some 35,000 plant species being used (9). Plants have evolved many protective defenses against pests and infection in the form of phytonutrients. These defenses are better developed in organic foods because of selective adaptive pressures necessary to resist pests, infections, and variable climate conditions (10, 11).

During time studies on plants were very limited. It can be estimated that only about a third of the million or so species of higher plants have been identified and named by scientists, and of these only a small fraction has been studied (12).

Bidens tripartita, a flowering plant from the genus Bidens, family *Compositae*, subfamily *Asteroideae* was widely used in traditional medicine for its antiseptic, anti-inflammatory, antioxidant, astringent, diuretic, febrifuge, narcotic and sedative effects (13, 14).

Bidens tripartita, an annual plant, 30-100 cm in height with yellow flowers is commonly known as Three-lobe Beggarticks, Three-part Beggarticks, Trifid Burmarigold.

Different phytochemical researches revealed that *B. tripartita* contains a significant amount of active substances, such as: flavonoids, xanthophylls, volatile oil, acetylene and polyacetylene, sterols, aurones, chalcones, caffeine and tannins proved to be involved in the pharmacodynamic effects of the plant (15, 16, 17, 18).

This medicinal plant is usually used in the treatment of acute respiratory infection, catarrhal rhinitis, angina, colitis, gout, or chronic dysentery (19, 20).

The present study is an *in vivo* biocompatibility evaluation of extracts from *Bidens tripartita*. The influence of this vegetable product on blood count, immune parameters level, some serum enzymes activity and other biochemical constants were assessed. Changes in different blood cells counts and levels of biochemical parameters were estimated up to 24 hours following *B. tripartita* extract intraperitoneal administration in mice.

MATERIAL AND METHODS

Animals. White male Wistar rats (200-250 g) were used. Lighting was on a 12 hours light/dark cycle (lights on at 6:00

a.m.), with standard laboratory food and tap water freely available, except during the time of the experiments. Before the experiment, rats were placed on a raised wire mesh, under a clear plastic box and allowed 2 hours to acclimate to the testing room.

Procedure. The vegetable product used for the study was obtained after maceration and extraction in alcohol. Flower powder was dissolved in absolute chloroform, re-extracted and filtered. After a complete dryness the product was extracted by the addition of ethanol then evaporated. The chemical composition of extracts was determined (21). The administered dose of *Bidens tripartita* retained was 1/20 of lethal dose 50 (LD50). The experiment was carried out on white male Wistar rats (200-250 g) divided into 3 groups of 7 animals each treated intraperitoneally as follows:

Group I (Control): distilled water 0.1 ml/10 g weight;

Group II (coded BT-alcoholic): 200 mg/kbw alcoholic *Bidens tripartita* extract;

Group III (coded BT-aqueous): 250 mg/kbw aqueous *Bidens tripartita* extract.

All experimental procedures involving the use of animals were conducted according to the standards of the Ethical Committee on Animal Experiments at the "Grigore T. Popa" University, which are in compliance with the ethical standards of the European Community. Each animal was used only once and the duration of the experiments was kept as short as possible. For ethical reasons, all animals were sacrificed at the end of the experiment (22).

We evaluated the acute toxicity of *Bidens tripartita* extracts by assessing their effects on blood count, serum biochemical tests, and some immune system parameters.

Twenty-four hours and 14 days after substances administration, blood samples (0.5 ml) were taken from retro-orbital plexus to assess blood count, glutamic oxaloacetic transaminase (GOT), glutamic pyruvic transaminase (GPT) and lactic dehydrogenase (LDH) activity.

We also investigated the following immune parameters: phagocytic capacity of peripheral neutrophils (Nitro Blue Tetrazolium test-NBT test), and serum complement activity.

The NBT test highlights the metabolic modifications that occurred during ingesting, quantitatively related to phagocytosis and identified through the reduction of the Nitro Blue Tetrazolium (NBT). The hemolytic activity of complement in serum was determined by its functional ability to lyse red blood cells in vitro.

Statistical analysis of data. The data were presented as +/- standard deviation and significance was tested by SPSS Statistics for Windows version 13.0 and ANOVA method. P-values less than 0.05 were considered statistically significant compared to controls.

RESULTS AND DISCUSSION

There were no statistically significant differences between the percentage values of leucocyte formula elements in the peripheral blood between the laboratory animals which systemically received alcoholic *B. tripartita* extract or aqueous *B. tripartita* extract and controls (tab. I).

Laboratory analysis did not show significant differences in GOT, GPT and LDH levels between alcoholic *B. tripartita* extractm, aqueous *B. tripartita* extract and distilled water, elements suggestive for a good *in vivo* biocompatibility (tab. II).

There were no statistically significant differences in the phagocytic capacity of peripheral neutrophils and serum comple-

ment activity levels between rats treated intraperitoneally with alcoholic or aqueous *Bidens tripartita* extract and those treated systemically with distilled water (tab. III).

Phagocytic capacity of peripheral neutrophils (NBT%) and serum complement activity evaluation in control group and in groups treated with alcoholic *Bidens tripartita* extract and aqueous *Bidens tripartita* extract, respectively. Values are expressed as mean ± S.E.M. *p<0.05, **p<0.01 *vs* control

Groups/Time		NBT (%)	Serum complement activity (UCH_{50})
Distilled water	14 days	15.17	53.62
BT alcoholic	14 days	15.67	54.18
BT aqueous	14 days	15.33	53.22

CONCLUSIONS

It has been demonstrated that the alcoholic *B. tripartita* extract and aqueous *B. tripartita* extract intraperitoneally administered in rats determined modifications of blood parameters and biochemical responses similar to those of distilled water, indicative of good in vivo biocompatibility.

Systemic administration of alcoholic and aqueous extracts from *B. tripartita* in rats did not alter their immune reactivity as compared with controls.

These studies suggest that alcoholic and aqueous extract from *B. tripartita* may be suitable for *in vivo* use as a drug delivery system.

NEWS

N-3 FATTY ACIDS IN PATIENTS WITH MULTIPLE CARDIOVASCULAR RISK FACTORS

In previous trials, administration of omega 3 fatty acids have proven beneficial in patients who have been diagnosed with myocardial infarction or heart failure. The present trial was assessed to verify a possible benefit in patients who have a combination of cardiovascular risk factors and subclinical atherosclerotic disease, but had no history of myocardial infarction. Patients were randomized to receive omega-3 fatty acids (1 g / day) or placebo (olive oil). After 5 years of follow-up, in which 6244 patients received omega-3 fatty acids and 6269 patients received placebo, the number of deaths, heart attacks and brain were 733 in patients who received omega-3 fatty acids and 745 in that receiving placebo ($p = 0.58$). In conclusion, prophylactic administration of omega 3 fatty acids in a dose of 1 g / day has not been shown effective in reducing cardiovascular morbidity and mortality in patients accumulating cardiovascular risk factors. (The Risk and Prevention Study Collaborative Group, n-3 Fatty Acids in patients with multiple cardiovascular risk factors, *N Engl J Med* 2013; 368: 1800-1808).

VALUE OF ICDAS INDEX IN A PRESCHOOL COMMUNITY FROM IASI (Abstract): The International Caries Detection and Assessment System (ICDAS) is a clinical scoring system for use in dental education, clinical practice, research, and epidemiology. The ICDAS is designed to: lead to better quality information to inform decisions about appropriate diagnosis, prognosis, and clinical management at both the individual and public health levels. It provides a framework to support and facilitate personalized management of the caries process and dental decay for improved long term health outcomes. **Aim:** This baseline study aims to find out the distribution of the caries lesions in primary teeth and their associations between the socio-economic statuses of families, in an Iasi town preschool community (Romania). **Material and methods:** The study series included 500 children (276 girls, 224 boys), aged 3-7 years old (43 subjects aged 3-3, 9 years, 126 subjects aged 4-4, 9 years, 186 subjects aged 5-5, 9 years, 136 subjects aged 6-6, 9 years and 9 subjects aged 7 years), attending a Iasi town kindergarten, in which the ICDAS index, was applied. **Results:** The visits to the dentist are statistically correlated only with the average number of healthy teeth from the frontal and the lateral area. In other areas of the dental arch, there is no statistically significant data, but in the frontal area, the children that had visited the dentist present an average number of 3.5 healthy teeth, and the children that had not been to the dentist present an average number of 3.717 healthy teeth. The number of teeth with enamel destruction without dentin visibility is much reduced in children also, statistically significances being present only in lateral mandibular and maxillary areas. Though in lateral mandible area, this value varies from 0 (for children between 6-7 years old), to 0.1176 (for children between 5-6 years old). The frequency of tooth brushing, has a significant influence on the (ICDAS = 4) value in lateral mandibular and maxillary areas, where these values decrease, as the tooth brushing is more often. Though in lateral maxillary area, the value is 0.066 for the children that brush their teeth twice a day, for the children that brush their teeth once a day, the value is 0.0353 and for the children that brush their teeth occasionally the value is 0.018. **Conclusions:** This study confirmed the high caries level in this region. The total caries experience indicators are normally higher, in the mixed dentition because the primary teeth have been exposed longer for the risk factors of dental caries for example frequent sugar snacks and drinks. It can be concluded that ICDAS method, gives much more relevant information about caries process than other methods. The distributions of the ICDAS codes are correlated between the primary and the permanent molars of the mixed dentition. **Keywords:** ICDAS INDEX, CHILDREN, DENTAL CARIES.

The International Caries Detection and Assessment System (ICDAS) is a clinical scoring system for use in dental education, clinical practice, research, and epidemiology (1, 2, 3).

The ICDAS is designed to: lead to better quality information to inform decisions about appropriate diagnosis, prognosis, and clinical management at both the individual and public health levels. It provides a framework to support and facilitate personalized management of the caries process and dental decay for improved long term health outcomes (4, 5).

It was found that, in the USA, dental caries has been synonymous with presence of cavitation, or decay. In Europe, in the research community, the understanding of dental caries appeared to be more advanced than in America. The standards for measuring caries include clinical stages of the disease process which precede cavitation, not simply the decay in the tooth. This is beginning to change, but at the time of the review, this information was accurate (6, 7).

The ICDAS group met in 2009 and developed Coronal Primary Caries Detection Criteria (8). The ICDAS detection codes for coronal caries range from 0 to 6 depending on the severity of the lesion (tab. I).

TABLE I

ICDAS - description of codes (8)

Codes	Description
0	Sound
1	First Visual Change in Enamel
2	Distinct Visual Change in Enamel
3	Localized Enamel Breakdown
4	Underlying Dark Shadow from Dentin
5	Distinct Cavity with Visible Dentin
6	Extensive Distinct Cavity with Visible Dentin

This baseline study aims to find out the distribution of the caries lesions in primary teeth and their associations between the socio-economic statuses of families, in an Iasi town preschool community (Romania).

MATERIAL AND METHODS

The study series included 500 children (276 girls, 224 boys), aged 3-7 years old (43 subjects aged 3-3,9 years, 126 subjects aged 4-4,9 years, 186 subjects aged 5-5,9 years, 136 subjects aged 6-6,9 years and 9 subjects aged 7 years), attending a Iasi town kindergarten, in which the ICDAS index, was applied.

Clinical examination was performed by four dentists in daylight. Tooth surfaces were visually inspected and the suspect surfaces were explored with the dental probe. The children were given a toothbrush and toothpaste and requested to brush their teeth before the examination. The written informed consent form was signed by the parent/caretaker. Very few par-

ents/caretakers did not want their child to participate, and some children were absent from school in the day of the examination. Data about the socio-economic status of children families were obtained through a questionnaire filled out by the parent. Statistical processing of the obtained data was performed using *SPSS 17.0*®.

RESULTS AND DISCUSSION

The visits to the dentist are statistically correlated only with the average number of healthy teeth from the frontal and the lateral area. In other areas of the dental arch there is no statistically significant data, but in the frontal area (fig. 2), the children that had visited the dentist present an average number of 3.5 healthy teeth, and the children that had not been to the dentist present an average number of 3.717 healthy teeth (U = 28494.000, p = 0.023). In the lateral area, the children that had visited the dentist present an average number of 4.978 healthy teeth compared children that had not been to the dentist have an average number of 5,438 healthy teeth.

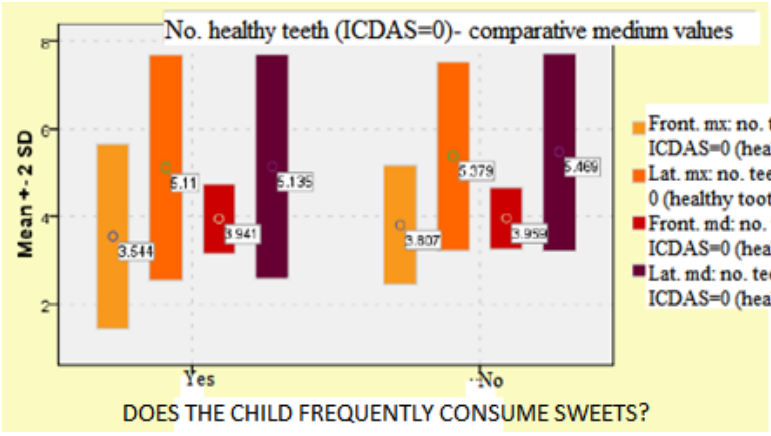

Fig. 1. Correlation between sweets consume and dental integrity

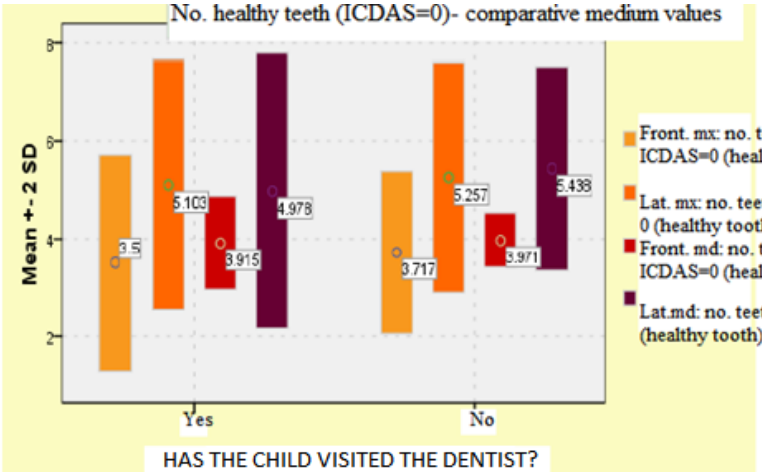

Fig. 2. Correlation between frequency of dentist visits and dental integrity

The frequency of sweets consumption affects the average number of teeth from the frontal and lateral maxillary area, lateral mandible area, but the frontal mandible area is not affected (fig. 1). The average number of teeth from this area is lower for the children that consume sweets compared to the children that do not consume sweets:

- in mandibular frontal area 3.54 (YES), compared to 3.807 (NO) – U=2307.000, p=0.006 statistically significant.
- in lateral maxillary area 5.11 (YES), compared to 5.379 (NO) – U=2319.500, p=0.045 statistically significant.
- in lateral mandibular area 5.135 (YES), compared to 5.649 (NO) – U=21613.500, p=0.001, statistically significant.

The same phenomenon happens with hard food consumption that influences the average number of healthy teeth from frontal maxillary area and lateral maxillary area, whiles the lateral mandibular area, is not influenced (fig. 3). The average number of healthy teeth is much higher in these areas, to the children that consume hard food compared to the children that do not have this eating habit.

- in frontal maxillary area a value of 3.708 (YES), compared to a value of 3.461 (NO) – U=25562.000, p=0.002 statistically significant.
- in lateral maxillary area a value of 5.286 (YES), compared to a value of 5.011 (NO) – U=25986.000, p=0.046 statistically significant.

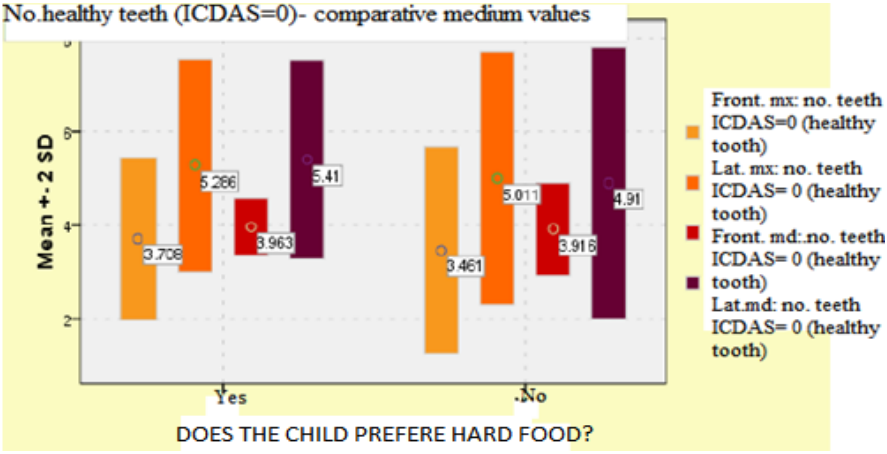

Fig. 3. Correlation between hard food consume and dental integrity

The number of teeth with enamel destruction without dentin visibility is much reduced in children also, statistically significances being present only in lateral mandibular and maxillary areas (fig. 4). Though in lateral mandible area, this value varies from 0 (for children between 6-7 years old), to 0.1176 (for children between 5-6 years old) p=0.017, which is statistically significant.

The frequency of tooth brushing, has a significant influence on the (ICDAS=4) value in lateral mandibular and maxillary areas, where these values decrease, as the tooth brushing is more often (fig. 5).

Though in lateral maxillary area, the

value is 0.066 for the children that brush their teeth twice a day, for the children that brush their teeth once a day, the value is 0.0353 and for the children that brush their teeth occasionally the value is 0.018, that is statistically significant (p=0,001).

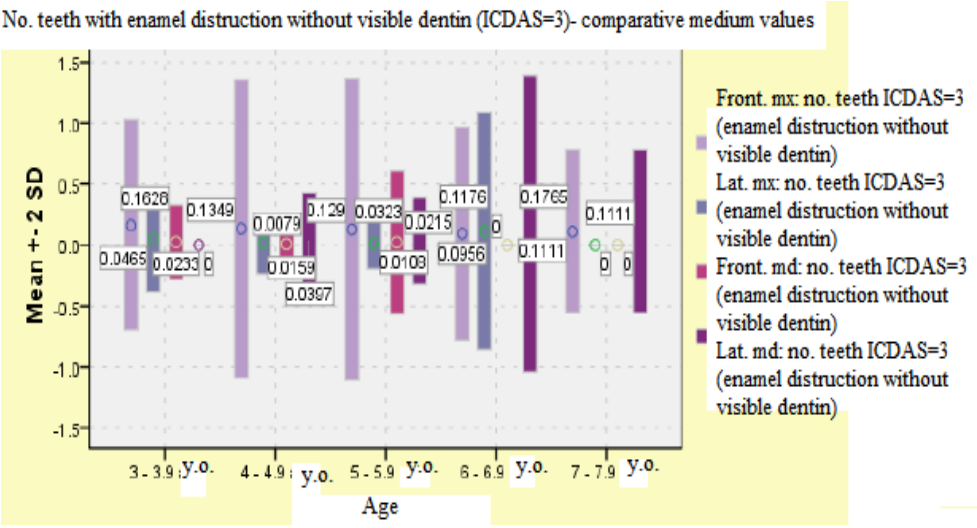

Fig.4. Distribution of teeth with enamel destruction without visible dentin

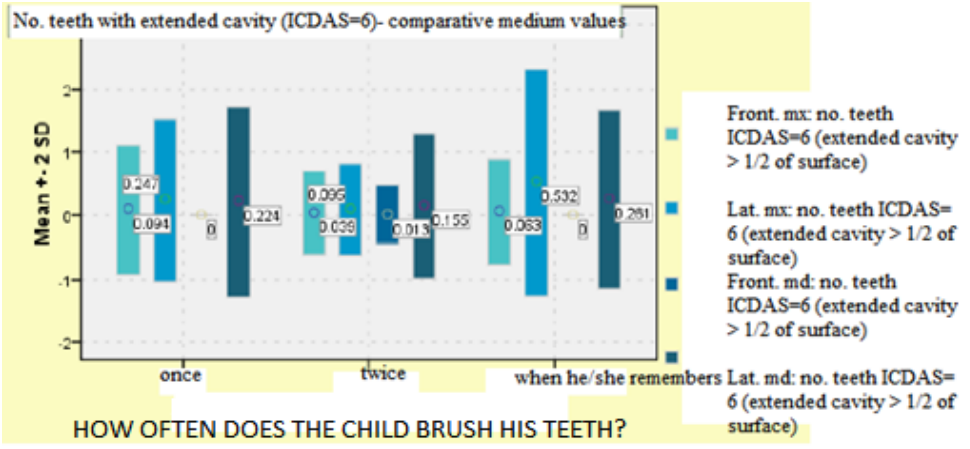

Fig.5. Correlation between teeth brushing frequency and caries cavity extension

The distribution of the ICDAS codes is difficult to explain. The code 2 (enamel caries detected on a wet tooth surface), might be easier to detect than the code 1 (enamel caries visible only when tooth surface is dry) and code 3 (minor cavitation on enamel only). This has been confirmed also in other ICDAS studies (9, 10).

CONCLUSIONS

This study confirmed the high caries level in this region. The total caries experi-

ence indicators are normally higher, in the mixed dentition because the primary teeth have been exposed longer for the risk factors of dental caries for example frequent sugar snacks and drinks.

High number of caries on the primary molars could be expected to predict caries in the permanent molars. The association of the number of caries lesions between the first permanent molars and the second primary molars was analyzed by Spearman correlation coefficient.

There were no statistical differences in the main number of dentine caries lesions according to the age. The older children could have been expected to have higher caries experience than the younger ones. However the older children had less dentine caries than the younger ones. This could be a worrying sign of the rapidly changing diet.

ICDAS is a especially valuable method for detecting the enamel caries lesions for planning the individual remineralization therapy or for monitoring the caries pattern at the population level.

It can be concluded that ICDAS method, gives much more relevant information about caries process than other methods. The distributions of the ICDAS codes are correlated between the primary and the permanent molars of the mixed dentition.

THE ESSENTIAL ROLE OF CONE BEAM COMPUTED TOMOGRAPHY TO DIAGNOSIS THE LOCALIZATION OF IMPACTED MAXILLARY CANINE AND TO DETECT THE AUSTERITY OF THE ADJACENT ROOT RESORPTION IN THE ROMANIAN POPULATION (Abstract): The impaction phenomenon is a pathological condition which is defined as the lack of eruption of a permanent tooth in the oral cavity. After third molar, the first permanent tooth impacted in the alveolar bone is the permanent maxillary canine, with varies from 1% to 3%. The **aim** of this study was to use the most recently imaging technique- CBCT, to evaluate the position of the impacted maxillary canine and to determinate the severity of root resorption of the adjacent teeth. **Material and methods***:* The all 230 patients of this study were referred to a CBCT scanning with Scanora machine and only the region of clinical interest was irradiated. **Results:** The age of the subjects was distributed between the ages of 11 and 42 years. From a total of 364 impacted canine teeth, 92 were side impacted canines, 97 right impacted canines and 87 were left impacted canines. **Discussion**: We report a lateral incisors root resorption present in 54.37% and 24.29% the resorption of central incisors. **Conclusions**: The use of CBCT in patients with impacted canines has potential diagnostic and may influence the planning of treatment. Also the CBCT can be a genuine method used to rectify, to diagnose and to make a suggestive treatment for the resorption of the root of incisors. **Keywords**: CBCT, IMPACTED CANINE, ROOT RESORPTION.

The impaction phenomenon is a pathological condition which is defined as the lack of eruption of a permanent tooth in the oral cavity, and was reported for the first time in 1922. The first permanent tooth impacted in the alveolar bone is third molar. After the third molar, the most frequently impacted tooth is the permanent maxillary canine, with varies from 1% to 3% (1). The canine impaction may be either vestibular or palatal and, in Europeans, the palatal impaction is 2-3 times more frequent than the vestibular impaction (2).

Most recently, in our medical practice we can used 3D investigations to locate the impacted maxillary canine and to appraisal

the root resorption of the adjacent teeth. As a starter, several studies used the CT technique, but for certain reasons it was replaced with the CBCT, owing to a reduced cone shaped X-Ray beam, size of the scanner, radiation dosage, time needed for scanning and much lower costs (3, 4, 5).

According to the CBCT imaging, a more comprehensive orthodontic diagnosis and more accurate treatment planning is possible. In 2003, Becker and Chaushu (6) announced that for patients who were younger than 20 the success of the impacted maxillary canine was 100%, while for the patients who were older than 20 the success was only 69.5%.

Therefore, the aim of this study was to use the most recently imaging technique-CBCT, to evaluate the position of the impacted maxillary canine and to determinate the severity of root resorption of the adjacent teeth.

MATERIAL AND METHODS

The sample consisted of 230 patients (132 female and 98 male, ranging in age from 11 to 42 years) from the Department of Orthodontics, University of Medicine and Pharmacy "Grigore T .Popa" Iasi, Romania and from a private Office "Oral Dent". The scanning investigation was developed at the Department of Dental Radiology, University of Medicine and Pharmacy "Grigore T. Popa" - Iasi, Romania, at "DDI" and "Explora Rx" Office.

The patients were referred to a CBCT scanning and only the region of clinical interest was irradiated, using a dentoalveolar field of view (small FOV - approximately 5 cm or less). The scan parameters were exposure time 18 seconds, voxel size resolution of 125 μm, tube current of 5mA and a tube voltage of 80 kV.

RESULTS

The age of the subjects was distributed between the ages of 11 and 42 years. From a total of 230 patients, 132 were female (57.4%) and 98 were male (42.6%). Of the 364 impacted canine teeth from the subjects, 92 were both side impacted canines (fig. 1, 2), 97 right impacted canines and 87 were left impacted canines.

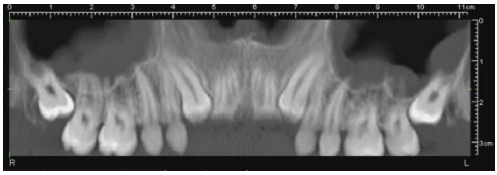

Fig. 1 Two-dimensional (2D) cone beam computed tomography image of a 19-year-old male with a bilateral impacted maxillary canine showing panoramic reconstruction for maxillary jaw.

Fig. 2. The cone beam computed tomography image of the same a 19-year-old male with a bilateral impacted maxillary canine showing axial slices, reveals a close contact with the lateral incisor and a large periapical space, highlighting an irregular outline which representing early apical resorption.

We selected the patients taking into account the age in 4 categories: group A (11-18 years), group B (19-26 years), group C (27-34 years), group D (35-42 years). We attend the position of canine, contact with incisors and incisors root resorption (tab. I).

We recorded following parameters (7, 8):

1. *the distance between the canine and*

occlusal plane in mm (fig. 3);

2. *the angle between the canine and occlusal plane;*
3. *the angle between the long axis of the canine and midline sagittal plane (fig. 3);*
4. *the angle between the long axis of the impacted canine and long axis of the central incisors in degrees (fig. 3);*
5. *relationship between the impacted canine and incisors:*

a) an existent contact- the distance between crown of the permanent canines and the adjacent incisors was less than 1 mm;

b) nonexistent contact- the distance between the crown of the permanent canines and the adjacent incisors was more than 1 mm.

6. *severity of root resorption to lateral incisors* (9)*:*

a) no resorption: intact root surfaces;

b) slight resorption (fig. 4 ,5): resorption extending up to half of the dentine thickness to the pulp;

c) moderate resorption (fig. 6): resorption midway to the pulp or more with the pulp lining being intact;

d) severe resorption (fig. 7): the pulp is exposed by the resorption.

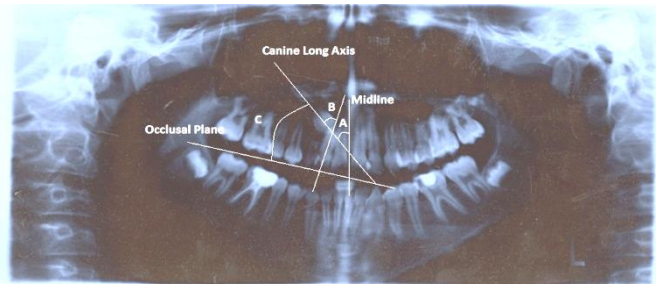

Fig. 3. Panoramic view illustrating reference lines and angular measurements. (A) Angle of impacted canine to the lateral incisor, (B) angle of the impacted canine to midline, and (C) angle of impacted canine to occlusal plane.

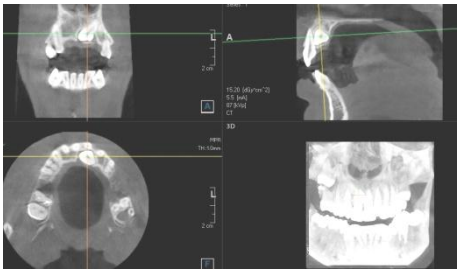

Fig. 4. The cone beam computed tomography image of a 21-year-old female with an impacted maxillary left canine showing axial slices (A); image B and C show the two-dimension (2D) reconstruction of coronal and respectively axial slices; as well as a 3D model that were used to exhibiting the left impacted maxillary canine superposed on the top of root of lateral incisor, highlighting slight root resorption of the left maxillary lateral incisor.

Fig. 5. Ortho-radial reconstruction through the center of lateral incisor shows a decrease radiopaque in the apical area, with a slightly irregular of the tip-apex which are suggestive for a slight root resorption.

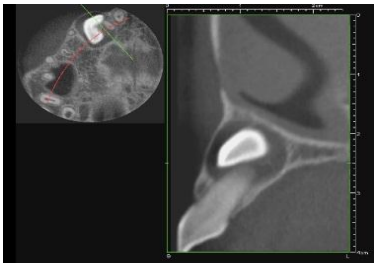

Fig. 6. Ortho-radial reconstruction tangent to the distal surface of the lateral incisor highlights the follicular sac that surrounds the lateral incisor apex, with a net reduction of apical opacity, suggesting a moderate resorption at this level.

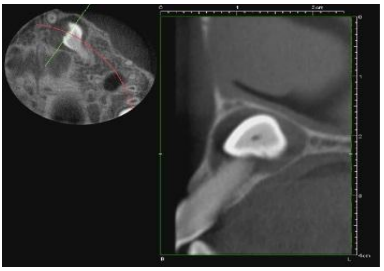

Fig. 7. Para axial reconstruction tangent to the distal surface of lateral incisor with a clear contact with the canine follicular sac, which cause resorption in the record of 1/3 of the apical area of the root, representing a severe root resorption.

TABLE I

Distribution of patients after the age in 4 categories and attend the position of canine, contact with incisors and incisors root resorption.

Age group	11-18		19-26		27-34		35-42	
	No.	%	No.	%	No.	%	No.	%
Canine localization Line of the arch	21	22.1	9	14.1	5	11.6	3	10.7

DISCUSSION

Many years 2D imaging modalities have been used in medical dentistry. Today, CBCT is the most frequently applied in

orthodontics, implantology, endodontics, maxillo-facial surgery (9).

A causative factor for the impacted canine is the lack of space. Many articles, describe that the etiology of the impaction canine remains unclear, but on the other hand, many studies sustain the fact that the impacted maxillary canines may result in several complications. It is very important to diagnosis the root resorption of the adjacent incisors when we have to plan the treatment for impacted maxillary canine. It has been demonstrated many time that with CT or CBCT it is possible to detect areas of resorption that are not detectable on the basic clinical and intraoral radiographs (7).

In this study lateral incisors root resorption were present in 54.37% and 24.29% the resorption of central incisors. If we compare with Ericson et al. study (5), the percentage of lateral incisors resorption was 38% in a CT study of 156 ectopically impacted maxillary canines lower than 54.37%, but also the reported percentage by Walker et al. (7) of 66.7% was higher than ours. On the other side, the percentage of the central root resorption was higher than reported by Ericson and Kurol (5), 9 % and Walker et al. (7), 11.1% . Walker et al. (7) evaluated all 27 patients of different ages with the NewTom QR-DVT 9000 and Ericson et al. (5) evaluated all 107 children with basic clinical and intraoral radiographic investigation which were supplemented with the computerized tomography. In the present study, radiological investigations consisted in using only CBCT. Obviously differences between studies may be explained based on the following criteria: age range and the ability and experience of using CT and CBCT images.

CONCLUSIONS

Since root resorption is asymptomatic, early detection by radiographic examination is essential for correct diagnosis and treatment. This technique is perfectly suited in cases of impacted maxillary canine and help us to reduce unnecessary radiation dose, cost and time.

NONINVASIVE LASER THERAPY FOR OUTPATIENTS WITH CHRONIC INFLAMMATORY DISORDERS OF CERVIX (Abstract): Chronic inflammation of the cervix can develop cervical stenosis with infertility and cervical congestion is related with the cervical cancer. We create a review of main etiological agents and methods of screening and diagnose. We also make a short brief review of modern therapeutic approach. **Conclusions**: We follow the utility of LLLT through the following aspects: evolution, indications, results of Babeş-Papanicolau screening, cytology, clinical aspects. The results of the study will allow the complex system of treatment to be used in a large category of women. We appreciate that the procedure (used in our center also) will decrease the cervical pathology, the morbidity inside the treatment, the mortality through the evolution of cervical cancer. We propose the applicability for outpatients first and then as an integrated treatment method inside hospitals for a wide access**.** **Keywords**: CERVICAL CANCER, LASER THERAPY, CHRONIC INFLAMMATION.

The evolution of chronic inflammatory disorders of uterine cervix (CIDC) has an insidious character which increases the difficulty of evaluation of symptoms and treatment. First symptoms of cervicitis as an inflammatory process are usually vaginal discharges which increase after menstruation, pruritus and congestion of external genital organs, dyspareunia, bleeding after sexual contact and/or between menstruation, dysuria, lower-back morbidity and/or hypogastric pain (usually during sexual intercourse) (2, 4, 6). In severe cases we can notice abundant vaginal discharge, with bad smell and intense pruritus and colicky abdominal pain. Chronic cervicitis can evolve for years only with abundant leucorrhea; the patient gets used with this condition, without fever, pain, menstrual disorders of damage of sexual life. Most frequently complication appears with the development of inflammation of pelvic proximity organs: parameters, salpingitis, acute or chronic infections of urinary tract.

Chronic inflammation of uterine cervix can develop in evolution a cervical stenosis, followed by infertility. Chronical cervical congestion is in relationship with cervical carcinoma (cervicitis, chronical inflammatory process uncontrolled and not treated in time, lack of prophylactic measures, external genital organs hygiene and routine checks 1-

2 times/year). Chronical cervicitis usually does not determine neoplasia but favor its development, confirming the national and international statistics (3, 7). The treatment of chronical cervicitis can be seen as a prophylactic measure in the fight against cervical cancer or other localized malignant tumors. Babeş-Papanicolau test is an integrated part of routine gynecological exam. The test is used for the identification of abnormal cervical cells. Abnormal result for this test is not quite unusual, because the cervical cells are undergoing permanent modifications (approximately 15% of women tested every year have abnormal result); only 1% of these results show constant modifications which can evolve to a cervical cancer (3, 7, 8).

Cervical diseases, their usual complications, noninvasive laser therapy treatments become an acuteness actuality and have a significant importance (5, 7) worldwide in contemporary gynecology. Actually used screening procedures, in a certain succession for those patients included in high risk categories allow precocious diagnose and best therapeutical approach. During 1990-2005 cytology was used as a screening method and allowed the diagnosis with a three times higher frequency for the cases of chronic cervical inflammation, preneoplasic stages, in situ carcinomas and stage I.

This work analyses other potential etiological factors. We can mention here the path: chronical cervicitis → cancer (direct proportion). Last year's research (1, 7, 9) demonstrate a 97% of pathogenic germs inside lesion cervix: 44,5% aerobe gram (+) germs (white hemolytic streptoccocus 18,7%, group D streptoccocus 15,8%, α hemolytic streptoccocus 4,9%, group A streptoccocus 2,9%, enteroccocus and golden stafiloccocus 0,9%); 30,5% gram (-) germs (*E. coli* 24,7%, *Haemophylus* 4,9%) and *Proteus* 0,9%); 13,8% anaerobic germs. *Trichomonas vaginalis* was diagnosed in 46,5% cases, *Candida albicans* in 48,5%, *Chlamidia trachomatis* in 13,8% and *Mycoplasma hominis* in 10,8%. Herpetic viruses: type I was diagnosed in 8.9% cases and type II in 13.8% cases (tab. I). After these last researches all women should undergo a compulsory complete screening, to balance the lack of sanitary education (1, 6, 7, 8).

TABLE I

Different pathogenic agents implicated in cervical chronic inflammation

Infectious agent	**cytology type IV**	**cytology type III**
bacterias	11.2%	2%
candida albicans	18.3%	-
trichomonas vaginalis	21.2%	21%
chlamydia trachomatis+		
mycoplasma hominis	25%	
VHS tip I - II	4.3%	4.3%

For the reduction of morbidity and mortality from cervical chronic inflammatory diseases we consider decisive the following aspects: systematic cytological and clinical checking for all women sexually active no matter age, with registration of data in health notebook; Babeş-Papanicolau routine test, recognized worldwide.

The analyze of 952 pathological cytotests promotes the idea that suspect lesions appear in 10,5% cases compare to 86,5% benign lesions and 3% malignant lesions.

The implication of microbial, parasite and viral agents in the etiology of lesional cervix with epithelial cervical disorders, benign and atipic is expressed by different cytological aspects which differ through the etiologic agent (1, 7, 9).

Some authors realized a prospective study on 101 clinical cases of lesional cervix; biological specimens were prelevated for evaluation of pathogenic agents and parasites. They notice high frequency for *Candida, Trichomonas, Chlamydia and Mycoplasma*. The protocol consisted of: correct patient history, gynecological clinical exam, routine exfoliative cytology for all patients, and association of repeated cytology with biopsy (for persistent inflammatory signs against all adapted treatment).

The elements which were followed: age – 168 (62,01%) women between 40-50 years had repeated chronical cervical inflammation distress treated many times before; place of living – 219 (67,80%) urban and 104 (32,19) – countryside; profession - 97 (30,03%) university degree, 226 (69,96%) high school; marital status - 94 (29,10%) married once, 157 (48,68) remarried, 72 (22%) married and divorced; obstetrical history – 12 (3,71%) nuligeste nulliparous, 214 (66.25%) multiparous, 97 (30.3%) primiparous; aspect of the cervix on first exam – 189 (58,51%) erosive lesions, 86 (26,62%), ulcerated lesions, 48 (14,86%) congestive lesions; stages at first exam and what treatment they have followed.

The importance of chronic inflammatory process resumes in its high prevalence worldwide, especially for cervical cancer which represents the first cause of morbidity and mortality for women in Romania also. Nowadays the most efficient method of prevention for cervical cancer is Babeş-Papanicolau cytological screening, after that cervico-vaginal cytology and correct treatment of acute and chronic cervicitis (4, 7, 8).

More and more we can speak about cervical diseases as sexually transmitted affections, no matter which is the etiology. This statement is based on solid epidemiological arguments (higher risk with the increased number of sexual partners, for teenagers with precocious sex life, incorrect treatment of cervico-vaginal infections, acute or chronic. We can also note the common risk factors for all women: lack of annual gynecological check, lack of education and information for women in the countryside, important virological new findings (the association between *Human Papiloma Virus* and chronic neoplasic alteration inside cervical cells) (6, 7, 8). Plurifactorial etiology is highlighted by the presence of other factors also, which increase the risk for cervical cancer: smoking, drinking, long term usage of oral contraceptives ($\geq$ 3-5 years).

The simptomatology for chronical cervicitis is reduced, at least in first stages and can be notable in advanced stages when becomes manifest. The alert signal for all women should be unexpected bleeding, which is in fact sign of important inflammation. In the beginning it is small bleeding, especially on intercourse. Together with bleeding can appear: leucorrhea (first white and then pale pink and finally with bad smell), vaginal discharge more and more important and with bad smell, pain in the *cul-de-sac* or pelvic pain which shows associated inflammatory signs, eventually extensive.

The correct diagnose must follow certain steps: exam of exfoliative cytology,

complete gynecological exam, biopsy – final step of the diagnosis, which brings the doubtless diagnose. Correct patient history can suggest us one specific category of women with higher risk for developing cervical cancer at certain point. From this point of view we can distinguish: 1. Minimal risk: women without sexual activity, who use barrier contraception, age more than 50 years, with repeated periodic gynecological exams and cytology. 2. Medium risk: women with usual sexual activity, with abortions and/or high number of natural deliveries before, women with persistent cervical ectropion. 3. High risk: women with early onset of sexual life (under 18), with multiple sexual partners, with many marriages, low socioeconomic status, low or absent hygiene.

When we analyze the reaction of the body to LLLT we can discover an integrated system of effects which include cellular/tisular modifications and control organism systems modifications. Usually we use two main methods of sanguine intravenous irradiation with red spectrum and simultaneous percutaneous irradiation and transmucosal, especially with infrared spectrum. We project the fascicles on targeted affected organs, in combination with magnetic flux. Laser irradiation can also be used for patients with: coronarian diseases, diabetes, leuconevraxitis, thyroid pathology, septical complications after radio/ chemotherapy for oncologic patients.

Intravenous blood irradiation was experimentally proved to have following effects: correction of humoral and cellular immunity, incensement of nonspecific immunity of the organism, adjustment of peripheral blood flow, adjustment of blood haemostasis, vasodilatation, balancing the acid-basic equilibrium, improvement of O_2 transportation, intensification of antioxidant function of blood, stimulation of erythropoiesiss, rehabilitation of damaged DNA through irradiation, rehabilitation of metabolic processes which involve proteins, lipids and carbohydrates, stimulation of rejuvenating process (tab. II).

TABLE II
LLLT therapy for cervical chronic inflammatory diseases

Recommended therapy (J/cm2) - acute - chronic	2.5 (1.8-3.3) 2.0 (1.3-3.0)
Recommended frequency (Hz) - acute - chronic	3.0 9.12
Time of therapy for max power (min.)	1.44 (acute), 1.23 (chronic)
Number of treatments in a weak - acute - chronic	Daily 3/week
Total number of treatments - acute - chronic	2 - 5 6 -12
Recommended BTL sound	(infra)red
Recommended sound power	30 mW

For the efficacy of treatment we have to follow some parameters: irradiation with optic accessory for gynecology, direct cer-

vical irradiation, laser therapy for affected areas.

CONCLUSIONS

Correct usage of LLLT through follow-up of evolution, indications, reported to Babeş-Papanicolau cytology and clinical gynecological exam has given very good results for all categories of patients.

The utilization and widening the area of LLLT usage is a goal for the future for our country too. In our medical center we have been using this technique for approximately 10 years. We appreciate that it will conduct to a decreased number of cervical inflammatory diseases. We also appreciate for the future a lower morbidity rate for this treatment and a lower mortality rate for chronic cervical inflammatory affections and also a better limitation of the evolution towards cervical cancer.

We propose the applicability in all medical centers, especially for outpatients, for a larger addressability for women from all population. These conditions have limited costs; do not induce work incapacity, usage of powerful drugs, adverse solutions, without pain.

INFLUENCE OF PREOPERATIVE KNEE DEFORMATION ON TENSION FORCE IN POSTERIOR STABILIZED KNEE ARTHROPLASTY (Abstract): Gap-dependent total knee arthroplasty involves applying a tension force to open the joint space. Intuitively, this force is dependent on the degree of joint deformity. **Aim:** The study aims at determining the amount of force and its influence on morphological parameters. **Material and methods**: In a group of 70 patients in whom total knee arthroplasty was performed ligament tension force was calculated and the influence of various individual morphological parameters was evaluated. **Results**: Statistical analysis showed that tension force is individual, dependent on knee deformation. **Conclusions**: Ligament tension force cannot be determined preoperatively, it requiring the use of appropriate tensioning devices. **Key words:** TENSOR, BALANCE, PRESSURE, PROTHESES

The two ways to place a total knee endoprosthesis are the controlled resection technique and gap-dependent technique. There are no data showing superiority of one of them, although some studies show a better positioning of the femoral component in the second case (1, 2). In both cases, the use of computer technology has made an improvement (2, 3). It helps in calculating directions and angles in the first case, and pressures/forces in the second, to prevent unstable knee (4, 5). In both cases ligamentous tension will determine the subsequent behavior of the knee. Of course, too low tension will cause laxity. Instead, there are articles showing that too much tension will cause increased imbalance (6). This is logical because if two different rigidity ligaments are stretched the tension difference increases. The question is: what the optimal ligamentous tension is. During the last period, ligament tensioning devices became available. Some of them generate a fixed force; others allow the force to be adjusted by the surgeon. However, a currently widespread idea is that a fixed force of 177-200 N regardless of the patient is necessary (7 - 13). Certainly the opening force must be applied with reduced patella. But it is curious that for different people, we create different spaces and fill them with prostheses of different sizes by applying the same force. Apparently, the greater the opening, the ligamentous tension is

even greater. Muratsu has shown that increasing the force size increases the gap (6). This paper aims at clarifying what is the balance force and the factors that determine it.

MATERIAL AND METHODS

Patients group

Seventy patients with a mean age of 73 years (range 60-90), height 1.62 ±0.07 m, weight 796±160 N, BMI 30.85 +5.93 kg/m², and a body moment (weight * height) of 1296±285 Nm entered this study. Patients were operated between July 2010 and May 2011 by the same surgeon. Exclusion criteria were the use of a surgical approach other than anterior-medial, personal history of rheumatic disease, injury, osteotomy or knee arthroplasty, conditions that could alter the capsular structure, and the absence of data. All parameters showed a normal distribution. Patients presented preoperative mechanical axis deviation of -5.65 ± 8.44 ° HKA, range 22°(varus) - 13°(valgus), flexion of 115 ± 14° (range 80-135°), and extension deficit of 4 ± 5 ° (range 0-20 °). The investigations included a preoperative conventional goniometry based on which HKA, alpha, beta angles, tibial slope, and Caton index were calculated (14, 15).

Device

We used a fourth generation E-libra® digital ligament tensor (Synvasive Technology, Inc., Reno, Nevada, USA) (fig.1). It is able to achieve ligament balancing in position of 90° knee flexion by opening the lateral side and mark this point by measuring and displaying the relative pressures in the two compartments. Balance is achieved with reduced patella. The device consists of 3 components: a femoral component, a tibial component, and ligament balance measuring system by pressure sensors. Femoral component includes two parts: a fixed part, which is applied to the distal femoral osteotomy surface, and a moving part. This allows tension adjustment by opening the lateral ligament. The adjustment is made via an actuator (screw-gear). The center of rotation in the axial plane corresponds to the geometric center of the medial femoral condyle. This allows the natural movement of rotation. Tibial component is a classic spacer thicknesses corresponding to a gap of 10, 12, 14, 16 mm. Ligament balance measurement system consists of pressure sensors disposed within each medial/lateral compartment. The processor transmits a known voltage to the two sensors, and pressure variations are converted into electric current variations. This analog signal is converted to digital and then it is processed. The signals are transmitted through a transciever to the display. The power source is batteries. All items are covered and sealed in a single device that is calibrated and sterilized by

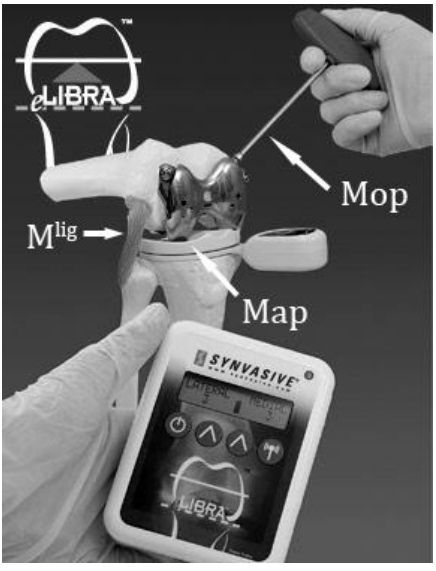

Fig. 1. E-libra www.synvasive.com

the manufacturer. The read-out unit displays the relative pressure values. Since the tensor comprises a worm-gear mechanism, the operator torque force Mop is amplified by the device to Map. To quantify the force distraction we have attached a Tochnichi torque screwdriver with a 10-100 cNm measuring scale. The assembly was calibrated using a Kirstler type force platform. The force generated by applying a progressive torque of 5 cNm was measured. For each value five determinations were made. The results revealed an excellent correlation coefficient $R^2 = 0.952$, and allowed us to calculate the multiplication factor.

METHODS

Prostheses were implanted using a technique sensor-dependent. Patients were anesthetized for ensuring complete muscle relaxation. After the tourniquet was inflated to 350 mmHg we practiced a medial parapatellar (transvastus) approach. Both cruciate ligaments were removed. The surgical sequence was the following: proximal tibial resection, distal femoral resection, measurement of femoral component, knee flexion, device insertion, knee balancing, cutting guide placement, anterior posterior femoral resection, and prosthesis implantation. All trances osteotomy were measured using a caliper to the tibial femoral contact point. We note the thickness of the tibial trances: medial tibia (MT) and lateral tibia (LT). After creating the space in extension, the surgeon considered the thickness of the meniscus (M) as the thickest that fits under a manual maximum distraction. It was inserted together with LBMS into the joint space in flexion of 90°. At that moment ligamentous tension was adjusted with a torque screwdriver. First we have achieved a maximal opening up, respectively the maximum stress on lateral collateral ligament to prevent the phenomenon of stress relaxation. Then we relaxed the device and achieved ligament balance. This was seen on the display. It noted the applied torque. The absolute force applied to the joints was calculated based on calibration.

Statistical analysis

Statistical analysis focused on the applied force. We studied the influence of various parameters on the force. These were anthropomorphic (height, weight, body moment), radiological (HKA angle, alpha, beta, tibial slope), clinical (flexion, extension), intraoperative and prosthetics (femoral and tibial size) data. Intraoperative parameters were MT, LT, M; medial / lateral opening MO / LO, where the opening is defined as the difference between the thickness of meniscus and the amount of resected bone; tibial tilt (TT) as the difference between the amount of resected bone at lateral tibia (LT) and medial tibia (MT), respectively (fig. 2). The relationship be-

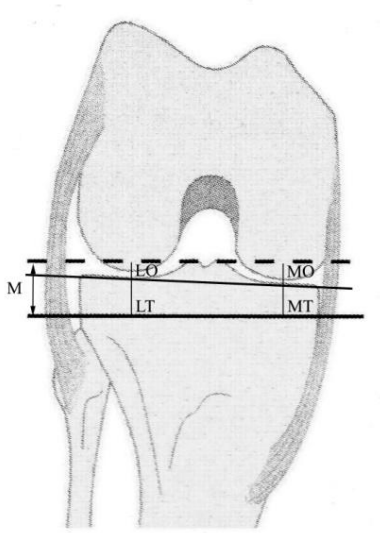

Fig. 2. Intraoperative parameters

tween the force and different parameters were analyzed using SPSS software. We used bivariate correlation tests, partial correlation, and ANOVA.

RESULTS

When placing the pressure sensor, the pressure was always higher in the medial compartment. Opening the lateral side allowed the two pressures to equalize. Balancing force was different for each patient with an average of 200 ± 124 N, range 72 to 699 N. As the values did not follow Gaussian distribution, the normalization was done by logarithms. The factors that showed a statistical correlation level of 0.01 were in the order of correlation coefficient: tibial tilt (TT), HKA angle, and femoral component size. The greater the tilt more force is required (fig.3). From the partial correlation analysis we found that this is largely due HKA angle, as between TT and HKA there is dependence.

As to the influence of joint line height, ANOVA tests revealed a significant positive/negative relationship between medial/lateral opening (MO/LO) and the force. However, the size of the meniscus (M), thus implant thickness did not correlate with the opening_force.

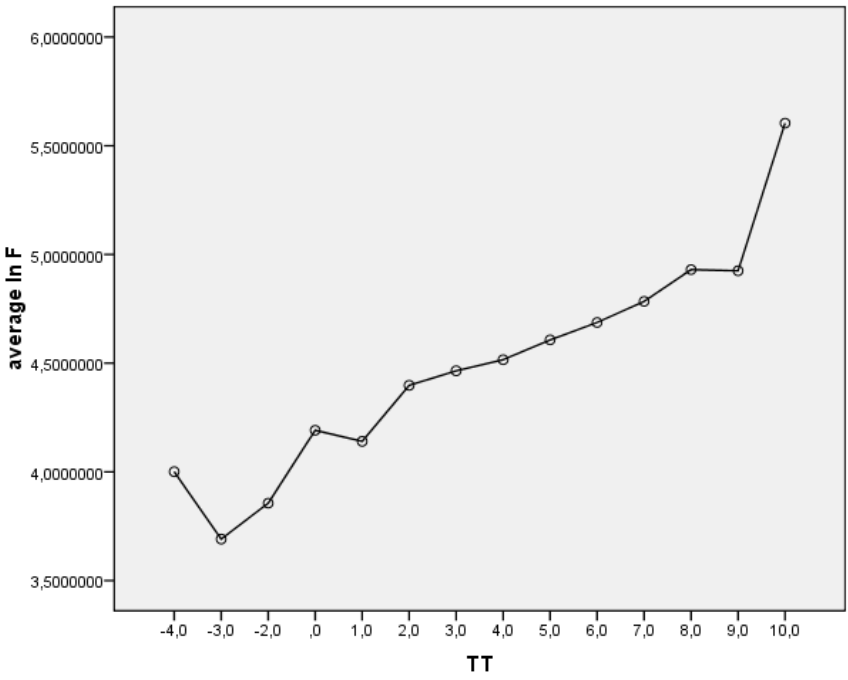

Fig. 3. Correlation between inclination of the tibia (TT) and force F

DISCUSSION

This study suggests the need of using customized force. This seems to come naturally: every individual is unique, with specific parameters. But our findings are in conflict with other studies that use fixed force. Its value derives from their experience in calculating the force needed to

open the joint space and required to insert total knee prosthesis (12). Even our study did not show an influence of implant thickness on the tension force. But the collateral ligaments have coefficients of elongation that differ from individual to individual. So, a fixed force will cause different openings in different patients. Based on these results, we aimed at finding the factors that influence the amount of force and how many of them are operator controlled or can be controlled. During surgery, the surgeon makes three balance-related gestures: ligamentous release, tibial osteotomy, and meniscus thickness choice. The first gesture is completely subjective. The other two change the joint line height and by default the size space. There are studies that show that if, in the same patient, we apply larger forces we get larger spaces (6, 16). The converse is also true: choosing the thicker meniscus ligament will generate higher tensions. Not only the meniscus thickness is important, but also the amount of resected bone. This explains the positive correlation between force and medial opening. However, lateral opening correlates negatively with force. The logic of these findings is revealed by tibial tilt. For the same elevation of the joint line, a greater tilt of the tibia suggests a greater imbalance between ligaments resulting from osteotomy. Tibia inclination reflects the joint form, a result of the wear process (HKA angle), or its anatomy (posterior - condylar angle). Partial correlation test confirms the dependence of tibia tilt (TT) and wear joint described by HKA angle. However, there is no a strong relationship between the tibia tilt and the tension, probably due to the influence of other unrated factors.

CONCLUSIONS

We find that the ligamentous tension force is individual. It is partly influenced by morphological features, but it cannot be determined preoperatively, this requiring the use of appropriate tensioning devices.

DEVELOPMENTAL DELAY IN FRONTAL REGIONS OF THE BRAIN IN CHILDREN WITH ATTENTION-DEFICIT/HYPERACTIVITY DISORDER (ADHD)

In a study by Shaw et al regarding the cortical anomalies underpinning attention-deficit/hyperactivity disorder (ADHD), 234 children with ADHD and 231 normally developing children were examined and 837 neuroanatomic magnetic resonance images were acquired. The purpose of the study was to see if the delayed maturation of prefrontal cortical thickness, characteristic for ADHD, also extends to the maturation of cortical surface area and gyrification. The study found that surface area developmental trajectory was delayed in ADHD. According to the researchers, the median age by which 50% of cortical vertices attained peak area in the right prefrontal cortex, was 14.6 years in ADHD, significantly later than in normally developing children at 12.7 years (Shaw P, Malek M, Watson B, Sharp W, Evans A, Greenstein D. Development of cortical surface area and gyrification in attention-deficit/hyperactivity disorder. *Biol Psychiatry* 2012; 72(3): 191-7).

THAPSIGARGIN-INDUCED ENDOPLASMIC RETICULUM STRESS IS NOT ACCOMPANIED BY MITOCHONDRIAL MEMBRANE POTENTIAL DISSIPATION IN MURINE PRO-B CELLS **(**Abstract): There are almost no data concerning the involvement of endoplasmic reticulum stress (Ca^{2+} fluxes) in the apoptosis of the pro-B cell type Ba/F3. Thus, we aimed the characterization of thapsigargin-induced effects on Ba/F3 cells *in vitro*. **Material and method**: For some experiments Ba/F3 cells were treated with 1 μM thapsigargin for 24 hours. To compare, we used as positive control the effects of valinomycin 10 μM. The negative control Ba/F3 cells received no treatment for 24 hours. After that, all batches of Ba/F3 cells were incubated in the presence of 1 μM JC-1 (Sigma-Aldrich) at 37°C for 30 minutes. **Results**: From the normal Ba/F3 JC-1-control cells (20.000 events gated by flow cytometry) 77.61±2.90% are associating high and 22.39±2.90% lower mitochondrial membrane potential. In the case of thapsigargin, 75.49±1.78% of the Ba/F3 cells are associating high and 24.51±1.78% lower mitochondrial membrane potential. **Conclusions**: While mitochondrial permeability transition pore (MPTP) opening necessarily correlates with a loss of mitochondrial membrane potential (Ψ_{mt}), a decrease in Ψ_{mt} does not necessarily indicate MPTP opening. Also, endoplasmic reticulum stress regulation of high cytosolic calcium levels by thapsigargin may prompt the opening of the MPTP without necessarily triggering irreversible pore activation or subsequent apoptogenic factors in Ba/F3 cells. **Key words:** PRO-B CELLS, MITOCHONDRIAL MEMBRANE POTENTIAL, APOPTOSIS, THAPSIGARGIN, ENDOPLASMIC RETICULUM STRESS

The endoplasmic reticulum (ER) is an organelle entrusted with lipid synthesis, calcium homeostasis, protein folding, and maturation. Perturbation of ER-associated functions results in an evolutionarily conserved cell stress response, the unfolded protein response (UPR) that is also called ER stress. ER stress is aimed initially at compensating for damage but can eventually trigger cell death if ER stress is excessive or prolonged. Now the ER stress has been associated with numerous diseases (1).

The Ca^{2+}-binding protein sorcin regulates intracellular calcium homeostasis and plays a role in the induction of drug resistance in human cancers. Recently, an 18 kDa mitochondrial isoform of sorcin was reported to participate in antiapoptosis in human colorectal cancer (CRC), but information remains lacking about the functional role of the more abundant 22 kDa isoform of sorcin expressed in CRC. It was found the 22 kDa isoform to be widely expressed in human CRC cells, whether or not they were drug resistant. Its upregulation in drug-sensitive cells induced resistance to 5-fluorouracil, oxaliplatin, and irinotecan, whereas its downregulation sensitized CRC cells to these chemotherapeutic agents. Sorcin enhances the accumulation of Ca^{2+} in the ER, preventing ER stress, and, in support of this function, it was found that the 22 kDa isoform of sorcin was upregulated under conditions of ER stress. In contrast, RNAi-mediated silencing of sorcin activated caspase-3, caspase-12, and GRP78/BiP, triggering apoptosis through the mitochondrial pathway. These findings establish that CRC cells overexpress sorcin as an adaptive mechanism to prevent ER stress and escape apoptosis triggered by chemotherapeutic agents, prompting its further investigation as a novel molecular target to overcome MDR (2).

The goal of our study was represented by the characterization of the effects of thapsigargin, an endoplasmic reticulum stress inducer, on Ba/F3 cells apoptosis, using flow cytometry and JC-1 as an indicator of mitochondrial membrane potential dissipation.

MATERIAL AND METHODS

The IL-3-dependent mouse pro-B cell line Ba/F3 was maintained in RPMI 1640 (Sigma-Aldrich) supplemented with 2 mM L-glutamine, 100 U/ml penicillin, 100 μg/ml streptomycin, 10% heat-inactivated fetal bovine serum and 10% WEHI-3-conditioned media as a source of murine IL-3, in an atmosphere with 5% CO_2 and at 37°C (3).

Cells were grown at a density of around 5 x 10^5 per ml before treatment. For some experiments (in triplicate) Ba/F3 cells were treated with 1 μM thapsigargin for 24 hours. To compare, we used as positive control the effects of valinomycin 10 μM, a well known inducer of dissipation of mitochondrial membrane potential, also in triplicate. The negative control Ba/F3 cells received no treatment for 24 hours. After that, all batches of Ba/F3 cells were incubated in the presence of 1 μM JC-1 (Sigma-Aldrich) at 37°C for 30 minutes. JC-1 [5,5',6,6'-tetrachloro-1,1',3,3'-tetraethylbenzimidazolyl-carbocyanine iodide or $CBIC_2$(3)] is a very sensitive marker for mitochondrial membrane potential (Ψ_{mt}). To demonstrate the involvement of mitochondrial permeability transition pore (MPTP) activation we administered the inhibitor cyclosporine A (CsA), also administered in parallel in 1 μM concentration for 24 hours.

Ba/F3 cells were washed three times with phosphate-buffered saline (PBS, Sigma-Aldrich) at 300 x g for 5 minutes each and for the determination of JC-1 loading in mitochondrial membrane we used a FACS Calibur (Beckton-Dickinson) which was set up for JC-1 fluorescence.

The final concentration for dimethyl sulfoxide (DMSO) in the medium, used as a drug solvent, did not exceed 0.1%, having no cellular effects at this concentration.

The statistical significance of test results was highlighted using the Variance One-Way ANOVA, All Pairwise Multiple Comparison Procedures (Holm-Sidak method) and the results were expressed as

mean ± S.E.M (n = 3). Value of $p<0.05$ was considered statistically significant always.

RESULTS

From the normal Ba/F3 JC-1-control cells (20.000 events gated) 77.61±2.90% are associating high and 22.39±2.90% lower mitochondrial membrane potential as shown by JC-1in Fig. 1 (triplicate experiment).

The mitochondrial membrane potential variation is evident if we compare these cells with the negative control ones (no treatment, Fig. 2). For the negative control cells, the vast majority is found in the bottom left region, that means 99.45±0.55% (n=3).

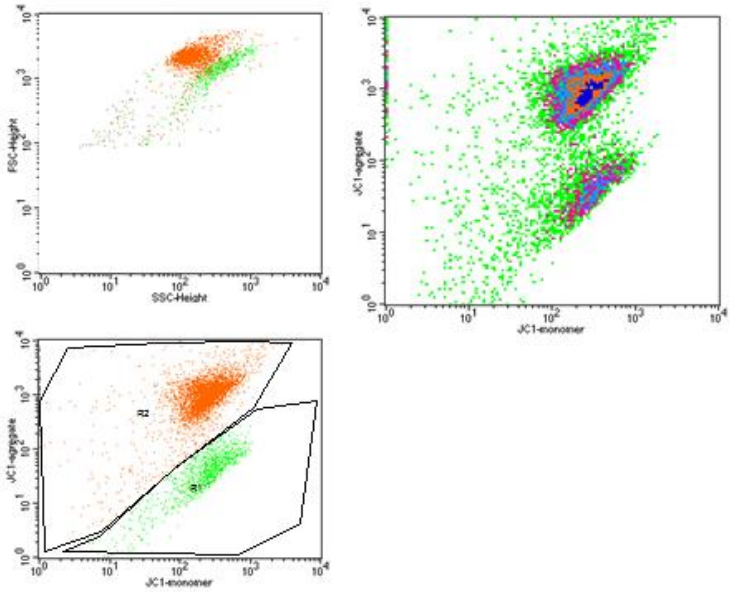

Fig. 1. Representative flow cytometry recordings of $1x10^6$ Ba/F3 cells/ml in the presence of 1 μM JC-1at 37°C for 30 minutes. As shown, 77.61±2.90% of the cells are associating high (R2 region) and 22.39±2.90% lower mitochondrial membrane potential (R1 region). $p<0.001$ as compared to control cells with no JC-1, data are expressed as mean ± S.E.M (n = 3).

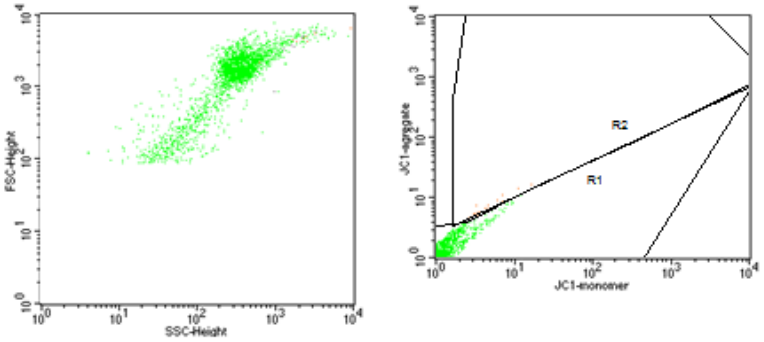

Fig. 2. Representative flow cytometry recordings of $1x10^6$ negative control Ba/F3 cells/ml. The vast majority is found in the bottom left region, that means 99.45±0.55%, data are expressed as mean ± S.E.M (n = 3).

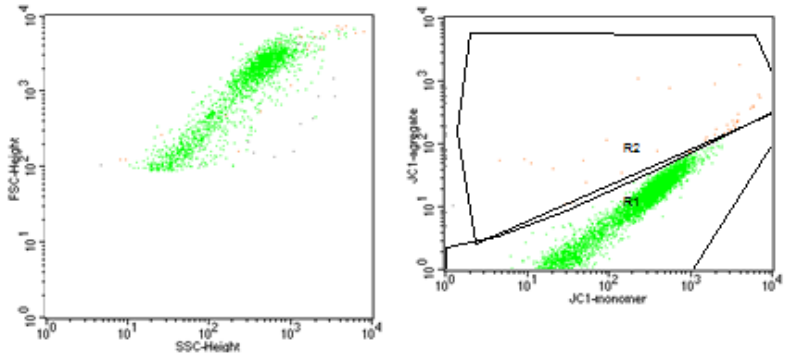

Fig. 3. Representative effects of 24 h treatment with valinomycin 10 μM on 1x10^6 Ba/F3 positive control cells/ml. The cells were stained with 1 μM JC-1 at 37°C for 30 minutes. As shown, only 1.69±0.95% of cells have mitochondria with high membrane potential (live cells, the R2 region), 98.31±0.95% being apoptotic (the R1 region). p<0.001 as compared to cells with only JC-1 and to cells with no JC-1, data are expressed as mean ± S.E.M (n = 3).

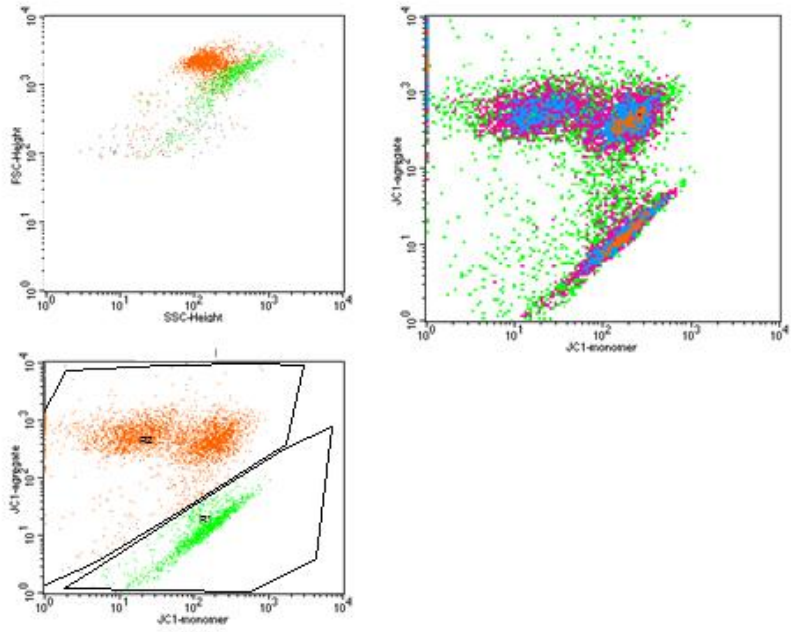

Fig. 4. Representative effects of 24 h treatment with 1 μM thapsigargin in culture medium on 1x10^6 Ba/F3 cells/ml. The cells were stained with 1 μM JC-1 at 37°C for 30 minutes. In this case, 75.49±1.78% of the Ba/F3 cells are associating high and 24.51±1.78% lower mitochondrial membrane potential. p<0.001 as compared to cells with only JC-1 and to cells with no JC-1, data are expressed as mean ± S.E.M (n = 3).

For comparison we used as positive control the effects of valinomycin 10 μM, a well known inducer of mitochondrial membrane potential dissipation, also in triplicate. After 24 h of treatment the R2 region contains only 1.69±0.95% of cells having mitochondria with high membrane potential (live cells), more than 98% being apoptotic (the R1 region, Fig. 3, n=3).

For some experiments (in triplicate) Ba/F3 cells were treated with 1 μM thapsigargin in culture medium for 24 hours (Fig. 4). In this case, 75.49±1.78% of the Ba/F3 cells are associating high and 24.51±1.78% lower mitochondrial membrane potential as shown by JC-1.

To demonstrate the involvement of MPTP activation we used the inhibitor cyclosporine A (CsA), also administered in parallel in 1 μM concentration for 24 hours. CsA dramatically reduced the valinomycin apoptotic effects on Ba/F3 cells, having no influence on thapsigargin treatment (data not shown).

DISCUSSION

The mechanisms regulating neutrophil apoptosis are basically unaffected by the aging process. However, a significant impairment of cell survival occurs in elderly individuals following neutrophil challenge with pro-inflammatory stimuli, such as granulocyte-macrophage colony-stimulating factor (GM-CSF). Treatments with the specific inhibitor of cytosolic calcium reuptake, thapsigargin, and/or the calcium mobilizing agonist, N-formyl-methionyl-leucyl-phenylalanine (fMLP), induced mitochondrial membrane depolarization, caspase activation, phosphatidylserine (PS) externalization, and DNA fragmentation in leukocytes from both young and elderly volunteers, although such effects were much more evident in aged leukocytes. Importantly, melatonin treatment substantially preserved mitochondrial membrane potential, reversed caspase activation, reduced PS exposure and forestalled DNA fragmentation in leukocytes from both age groups. In conclusion, melatonin is able to delay endoplasmic reticulum stress-induced apoptosis in aged leukocytes and may counteract, at the cellular level, age-related degenerative phenomena linked to oxidative stress (4,5).

The proteasome has been recognized as a druggable target in cancer cells, and this has led to searches for pharmacologic agents that target this cellular organelle for cancer therapeutic purposes. Syrbactins are a group of microbial metabolites consisting of two related families, the glidobactins and the syringolins. Some members of this group have revealed cytotoxic efficacy in tumor cells, and more recently it was discovered that they exert proteasome-inhibitory function. Some results show that two of these novel compounds are able to inhibit proteasome activity in the nanomolar range, reduce the expression of anti-apoptotic proteins survivin and Mcl-1, and cause severe ER stress, resulting in pronounced tumor cell death (multiple myeloma, Waldenstrom's macroglobulinemia, and lymphocytic leukemia). These anticancer effects can be synergistically enhanced when the agents are combined with thapsigargin, which further aggravates ER stress by a different mechanism. Taken together, the findings support the notion that syrbactin analogs may provide a structural platform for the development of novel cancer therapeutics, and that their efficacy may be further increased when complemented with other agents that trigger ER stress (6).

Autocrine motility factor/phosphoglucose isomerase (AMF/PGI) promotes cell survival by the pAkt survival pathway. Its receptor, gp78/AMFR, is an E3 ubiquitin

ligase implicated in ER-associated protein degradation. It was demonstrated that AMF/PGI also protects against thapsigargin- and tunicamycin (TUN)-induced ER stress and apoptosis. AMF/PGI protection against the ER stress response is receptor mediated as it is not observed in gp78/AMFR-knockdown HEK293 cells. However, AMF/PGI protection against the ER stress response by thapsigargin and TUN was mediated only partially through PI3K/Akt activation. AMF/PGI reduction of the elevation of cytosolic calcium in response to either thapsigargin or inositol 1,4,5-trisphosphate receptor activation with ATP was gp78/AMFR-dependent, independent of mitochondrial depolarization and not associated with changes in ER calcium content. These results implicate regulation of ER calcium release in AMF/PGI protection against ER stress and apoptosis. By regulating ER calcium release, AMF/PGI interaction with gp78/AMFR therefore protects against ER stress identifying novel roles for these cancer-associated proteins in promoting tumor cell survival (7).

CONCLUSIONS

While mitochondrial permeability transition pore (MPTP) opening necessarily correlates with a loss of mitochondrial membrane potential (Ψ_{mt}), a decrease in Ψ_{mt} does not necessarily indicate MPTP opening. Also, endoplasmic reticulum stress regulation of high cytosolic calcium levels by thapsigargin may prompt the opening of the MPTP without necessarily triggering irreversible pore activation or subsequent apoptogenic factors in Ba/F3 cells.

ACKNOWLEDGEMENTS

We have to thank to Prof. Ştefan N. Constantinescu from Signal Transduction Unit, Ludwig Institute for Cancer Research & "Christian de Duve" Institute of Cellular Pathology, Université Catholique de Louvain, Avenue Hippocrate 74, UCL 75-4, B1200, Brussels, Belgium, for his kind gift in Ba/F3 cells and for exceptional technical and reviewing help.

THE USE OF BETA BLOCKER *NEBIVOLOL* IN PATIENTS WITH CHRONIC OBSTRUCTIVE PULMONARY DISEASE IN ASSOCIATION WITH ARTERIAL HYPERTENSION

C. Martiniuc[1], T. Branishte[2]

1. IMSP Institute of Phtisiopneumology „Chiril Draganiuc" Chishinau
2. State Medical and Pharmaceutical University „Nicolae Testemitanu" Chishinau

THE USE OF BETA BLOCKER *NEBIVOLOL* IN PATIENTS WITH CHRONIC OBSTRUCTIVE PULMONARY DISEASE IN ASSOCIATION WITH ARTERIAL HYPERTENSION (Abstract): There were investigated 22 patients with chronic obstructive pulmonary disease in association with arterial hypertension initially and after 5 weeks of treatment with beta-blocker *Nebivolol* 5 mg/day. There were not detected any negative changes on bronchial permeability after treatment. Considerable improvement of endothelial function (from 7-12% to 17-35%, $p<0.05$) in parallel with decreasing of pulmonary artery, systolic (44.5±5.5 mmHg vs. 32.8±4.1 mmHg, $p<0.05$) and mean pressure (26.3±4.2 mmHg vs. 21.1±2.1 mmHg, $p<0.05$) – were observed after treatment. Thus, *Nebilet* is well-tolerated and highly effective in patients with chronic obstructive pulmonary disease in association with arterial hypertension. **Key words**: BRONCHIAL PERMEABILITY, ARTERIAL HYPERTENSION, BETA-BLOCKER, ENDOTHELIAL FUNCTION, MEAN PRESSURE.

Beta blockers hold one of the main positions in the structure of the complex treatment of patients with arterial hypertension and congestive heart failure (1, 2, 3, 4, 5, 9, 12, 13). Beta blockers reduce the cardiac output, change the susceptibility of the bar receptor reflex and block the peripheral adrenoreceptors (6, 7, 8, 10). Some beta blockers also depress the rennin secretion. Despite the above mentioned positive aspects, manifested by blocking beta II – receptors of the bronchial muscles, they also induce bronchoconstriction, increase the reactivity of respiratory tract and decrease or block the effects of the beta II inhaled agonists (9, 10). Therefore, there shall be prudence or avoidance of the use of beta blockers in patients with chronic obstructive pulmonary disease. That is why the international guidelines have established that bronchial asthma and chronic obstructive pulmonary disease are definitely contraindicated to the use of beta blockers in the treatment of arterial hypertension. *Nebivolol* (*NB, Nebilet, Berilin – Chemie, Menarini Group*) represents a superselective third generation beta blocker. The cardioselective index is of 293 (the proportion of beta blocker I adrenoreceptors and beta blocker II – adrenoreceptors). In order to make a comparison, one can observe the cardioselective index of athenol is of 15, of metoprolol – 25, bisoprolol – 119 (1, 2). The therapeutic dose of NB is of 5 mg/day. The compound has a prolonged action (more than 24 hours, in some cases, it reaches 30-32 hours), stimulates synthesis and discharge of nitric oxide

from the vascular endothelial cells, and has an antiproliferative effect against the smooth muscle cells which leads to physiological vasodilatation (3). The study of the effects of NB over the mechanics of respiration, the lung circuit and the endothelial function is of high interest.

The study of the efficiency and security of using NB in patients with chronic obstructive pulmonary disease in association with arterial hypertension.

MATERIALS AND METHODS

There were investigated 22 male patients with chronic obstructive pulmonary disease of moderate seriousness (Tiffeneau index<70%, 50%≤ VEMS <80%) in association with second degree arterial hypertension, 45-56 of age (average 52.6±2.54 years) and duration of illness of 7 to 20 years (average 14.3±7.7 years) – initially and after 5 weeks of treatment with NB. There were performed: spirometry (maximum and forced expirogram with the registration of the flux-volume and volume-time curves); standard electrocardiogram, Doppler echocardiography (to estimate the systolic pressure in the lung artery) – initially and after treatment with NB.

The endothelial function was estimated with the help of computerized photoplethysmography by making the test of reactive hyperemia. The endothelial dysfunction was considered when the index of the endothelial function was below 10%.

RESULTS AND DISCUSSION

The analysis of the safety and efficiency of the use of NB in patients with chronic obstructive pulmonary disease and arterial hypertension has not revealed aggravation of the evolution of chronic obstructive pulmonary disease and bronchial obstructive syndrome during the 5 weeks of treatment. There have been no significant changes of the bronchial permeability while studying the dynamics of the spirometry indexes (tab. I). There have been revealed certain tendencies of the increase of the forced expiratory volume per second (FEV1), of the forced expiratory flow in the middle of the forced vital capacity (FEF 25/75) and of the forced vital capacity (FVC).

The index of the endothelial dysfunction (after being tested with reactive hyperemia) increased considerably from 7-12% to 17-35% ($p<0.05$). A positive dynamic of the level of arterial pressure and FCC have also been observed: from the initial 156.33±15.5 mmHg to 136.57±18.12 mmHg and 86.72±7.4 heart beats per minute versus 70.56±3.88 heart beats per minute ($p<0.05$). The Doppler echocardiography revealed a moderate dilatation of the right parts of the heart (the telediastolic volume of the right ventricle - 28.6±0.11 mm) and light biventricular hypertrophy (thickness of the right ventricle anterior wall– 5.5± 0.3mm, and of the left ventricular posterior wall – 1.27±0.07). There was significant dynamics of pressure in the pulmonary artery (5-12%): systolic - from 44.5±5.5 mmHg initially versus 32.8±4.1 mmHg $p<0.05$) after 5 weeks of treatment; average – from 26.3±4.2 mmHg versus 21.1±2.1 mmHg and of the time of increase of the pulmonary flux – 100.5±11.4msec initially and 126.1±10.5 msec after the treatment with NB ($p<0.05$).

By „endothelial dysfunction" we understand a lack of balance of the endothelial factors which equilibrate the process of homeostasis, proliferation and vascular tonus. Nowadays, the endothelial dysfunction holds a main part in the pathogenic of pulmonary hypertensions both primary and secondary. Among the pathogenic reactions

that lead to the appearance of pulmonary hypertension, the impact of hypoxemia is first of all realized by the action of the latter over the structural and functional state of the endothelium of the small and medium pulmonary vessels.

TABLE I

Mechanics of breathing in patients with obstructive lung disease after the treatment with *Nebilet*

Indications	Actual value Initially/after treatment	Proper value Initially/after treatment	% of the Proper value Initially/after treatment
FVC, 1	3.73±0.5/ 3.85±0.7	4.16±0.7/ 4.22±0.4	89.66±11.2/ 91.22±10.7
FEV1, 1	2.20±0.3/ 2.26±0.5	3.46±0.7/ 3.50±0.7	63.58±9.9/ 64.57±7.7
PEF, peak expiratory flow, l/min	2.13±0.3/ 2.22±0.5	6.43±0.2/ 6.51±0.2	33.11±8.8/ 33.31±6.0
FEF 25/75 %, l/min	1.34±0.1/ 1.40±0.1	32.2±11.5/ 33.3±9.6	32.2±11.5/ 33.3±9.6
FEV1/FVC, Tiffeneau index	68.5±11.5/ 69.0±9.9	75.0±9.9/ 75.0±9.7	91.33±10.0/ 92.05±11.3

Based on photoplethysmography, the dynamics of the endothelial function was positive after treatment (tab. II): the cumulating values of the endothelial dysfunction (after being tested with reactive hyperemia) increased considerably from the initial 7-12% to 17-35% ($p<0.05$) and even doubled in some patients. The index of rigidity of the pulse wave decreased from 7.91±0.33% ($p<0.05$), the reflection index remained the same, 48.1±2.07 versus 47.7±2.4m/s. Similar tendencies were noticed after tests with reactive hyperemia, in comparison with initial data.

TABLE II

Dynamics of photoplethysmography parameters after treatment with *Nebilet*

Indexes	Initial	After treatment
Amplitude 1 (mm)	52.5± 4.1 (52.7± 4.4)	64.1±3.3 (72.7±3.0)
Amplitude 2 (mm)	25.0± 2.0 (23.2 ±4.5)	30.3±1.8 (28.3±2.2)
T (sec)	0.23±0.001 (0.23±0.01)	0.23±0.01 (0.23±0.01)
Height (mm)	1.82±0.05 (1.82±0.07)	1.64±0.03 (1.64±0.05)
Reflection index %	48.1±2.07 (44.1±2.2)	47.7±2.4 (39.0±2.7)
Rigidity index, m/s	7.91±0.35 (7.91±0.37)	7.45±0.33 (7.13±0.1)
Endothelial dysfunction index (%)	8.6±1.1	17.9±2.5

Legend: between brackets – data after the test with reactive hyperemia

The dynamic supervision of the indexes of rigidity and reflexion in patients with chronic obstructive pulmonary disease allows us to estimate the efficiency of the treatment, the state of the process of vascular remodeling and the diagnosis of the basic illness.

CONCLUSIONS

In patients with the bronchial obstructive syndrome in association with arterial hypertension the use of beta blocker *Nebilet* does not create the aggravation of bronchial permeability and improves considerably the endothelial function, the state of the central and pulmonary hemodynamic.

INCIDENCE OF CONGENITAL MALFORMATIONS IN THE IAŞI "CUZA VODĂ" MATERNITY HOSPITAL (Abstract): **Aim**: To update the data on the incidence of congenital malformations in our area and emphasize the importance of prenatal diagnosis. **Material and methods**: The study was conducted over a period of ten years and included 2211 cases with congenital malformations. Such parameters as the incidence of malformations over these years, gestational age at the moment of diagnosis, and mortality from congenital malformations were followed. Statistical and graphical data were processed with the help of SPSS 16.0 and MS Excel software. **Results**: The total prevalence of malformations was 3.52%, comparable with the data in the literature. Over this period a number of 262 cases (11.8%) ended in spontaneous miscarriage or termination of pregnancy for fetal abnormalities. A significant percentage of these pregnant women gave birth to their child, many of them dying shortafter. **Conclusions**: Congenital malformations remain the leading cause of mortality in neonates. In Romania, the advanced techniques of prenatal diagnosis being used only in specialized centers, and a large number of cases may escape early diagnosis. This study underlines the importance of a correct assessment of fetuses so that the discovery of fetal abnormalities at birth not to be a surprise. **Key words**: CONGENITAL MALFORMATION, INCIDENCE, MORTALITY

În România, în anul 1984 s-a realizat „Registrul naţional de malformaţii congenitale şi boli genetice" şi fişe de evidenţă pentru urmărirea evoluţiei cazurilor cu malformaţii. Cu toate acestea, registrul naţional de malformaţii nu aduce date suficiente privind valorile de incidenţă deoarece unele cazuri subclinice rămân nediagnosticate (bicuspidia valvelor aortice), altele nu sunt înregistrate (malformaţiile grave care au determinat moartea intrauterină a fătului) (1, 2).

Studiul s-a realizat în cadrul Spitalului Clinic „Cuza Vodă" Iaşi. Am înregistrat atât sarcinile cu malformaţii congenitale fetale decelate ecografic prenatal, cât şi nou-născuţii cu anomalii care nu au fost detectate la examenul prenatal. Scopul studiului a fost de a actualiza datele privind incidenţa cazurilor de malformaţii congenitale, în perioada 2001-2010 şi sublinierea importanţei diagnosticului prenatal.

MATERIAL ŞI METODĂ

În studiu am inclus 2211 cazuri cu malformaţii care au fost diagnosticate în unita-

tea noastră în perioada 1 ianuarie 2001 - 31 decembrie 2010. Parametrii urmăriţi au fost: incidenţa malformaţiilor raportată la numărul total de naşteri, mediul de provenienţă şi vârstă gestaţională a gravidelor, mortalitatea datorată malformaţiilor congenitale. Datele au fost preluate din condicile de naştere, condicile de mortalitate şi morbiditate neonatală, din foile de observaţie şi condicile de necropsii şi au fost introduse într-o bază de date realizată în acest scop cu programul Excel. Prelucrarea statistică şi grafică a datelor a fost efectuată cu programul *SPSS 16.0* şi MS Excel.

Malformaţiile congenitale majore şi minore au fost grupate în 8 categorii în funcţie de localizare: sistem nervos central, cord, toraco-pulmonare, tub digestiv şi perete abdominal, genito-urinare, ale membrelor, ale feţei şi sindroame genetice. Au fost considerate malformaţii majore anomaliile letale sau incurabile şi condiţiile asociate cu handicapuri severe sau care au necesitat intervenţie chirurgicală în primul an de viaţă (3).

REZULTATE ŞI DISCUŢII

1. Incidenţa totală a malformaţiilor în perioada 1 ianuarie 2001-31 decembrie 2010. În perioada studiată, în Spitalul clinic de obstetrică şi ginecologie "Cuza-Vodă" Iaşi, au fost internaţi 62709 nou-născuţi dintre care 2211 copii cu malformaţii. Incidenţa totală a malformaţiilor a fost de 3,52%, valoare comparabilă cu cele existente în literatura de specialitate (2) şi puţin mai mare decât cea evidenţiată într-un studiu anterior efectuat în acelaşi spital în perioada 1 ianuarie 1997- 31 decembrie 2001 (4). Incidenţa malformaţiilor a crescut de la 6,4% în 2001 la 15,6% în anul 2007, după care a prezentat o scădere semnificativă până la 7,3% în 2010 (fig. 1). Această constatare poate fi explicată prin creşterea factorilor de risc pentru malformaţii (5, 6). Din luna februarie 2005, unitatea noastră e devenit centru terţiar de diagnostic şi tratament, având ca efect şi creşterea adresabilităţii gravidelor cu suspiciune de anomalii fetale.

2. Repartiţia pe sexe a lotului luat în studiu în perioada 2001-2010. În cei 10 ani luaţi în studiu, din lotul de 2211 copii cu malformaţii congenitale, 916 (41,4%) au fost de sex feminin, 1295 (58,6%) masculin (fig. 2); 1042 (47,1%) au provenit din mediul urban şi 1169 (52,9%) din rural. Se remarcă o uşoară preferinţă pentru sexul masculin. Vârsta maternă a fost cuprinsă între 18 şi 46 ani, cu o medie de 31,2 ani.

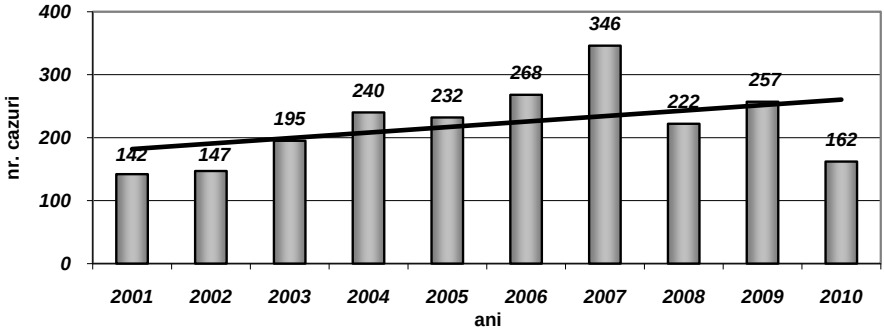

Fig. 1. Distribuţia pe ani a cazurilor cu malformaţii. Se remarcă o creştere a constantă numărului de cazuri până în anul 2007

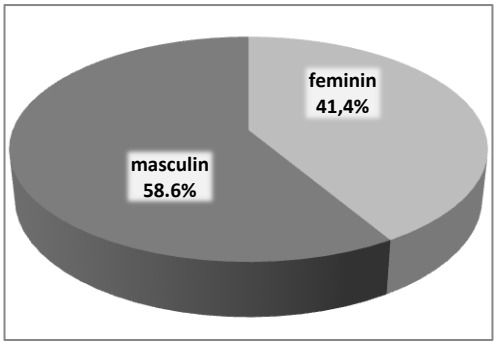

Fig. 2. Structura lotului pe sexe. Se observă o afectare preponderentă a sexului masculin comparativ cu cel feminin

3. Repartiţia pe mediul de proveniență a gravidelor din lotul studiat. Urmărind structura lotului pe medii de proveniență se observă diferenţe semnificative statistic (χ^2 = 22,824, p= 0,007 < 0,05) între cei 10 ani în privinţa structurii lotului pe medii de proveniență. Astfel, în anii 2004, 2005, 2007 şi 2008 majoritatea cazurilor au provenit din mediul urban, cu un procentaj maxim de 53,3% în anul 2004, în timp ce în ceilalţi ani majoritatea cazurilor au provenit din mediul rural, cu un maxim înregistrat în anul 2010 – 64,2% (fig. 3, 4).

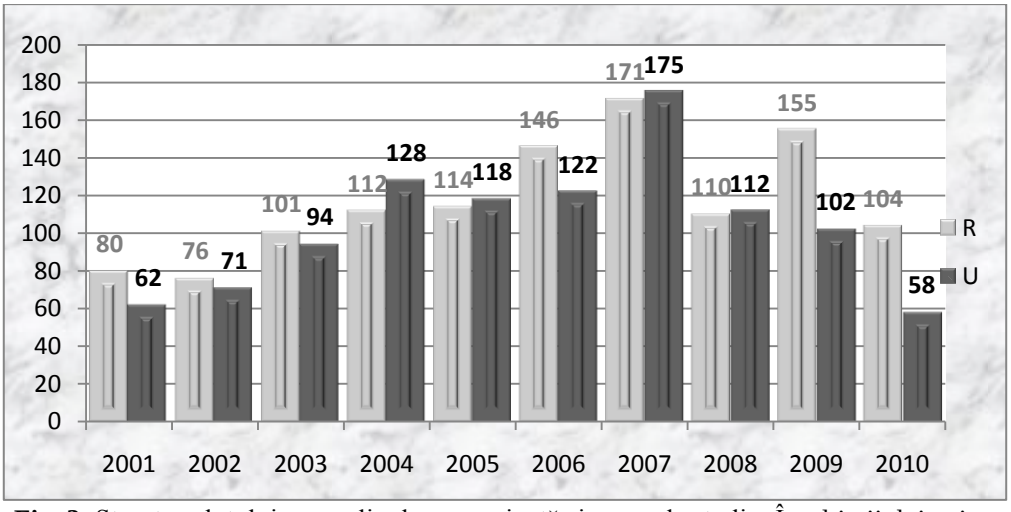

Fig. 3. Structura lotului pe mediu de proveniență şi pe an de studiu. În ultimii doi ani se observă o creştere semnificativă a cazurilor din mediul rural.

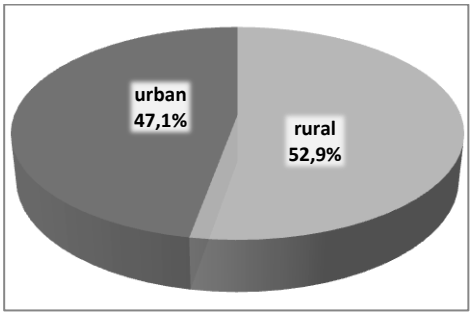

Fig. 4. Structura lotului pe mediu de proveniență

4. Analiza repartiţiei, în relaţie cu vârsta gestaţională. În perioada luată în studiu, din cele 2211 cazuri de malformaţii înregistrate în 262 cazuri (11,8%) sarcina s-a terminat prin avort spontan sau terapeutic pentru malformaţii grave incompatibile cu supravieţuirea. În restul cazurilor sarcina s-a încheiat prematur într-un procent de 47,5%. La termen s-au născut 41% dintre feţii cu malformaţii (fig. 5).

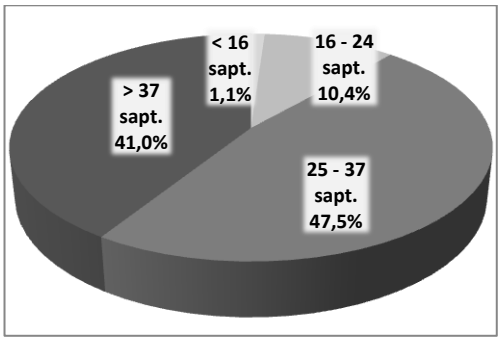

Fig. 5. Structura lotului după vârsta gestaţională

5. Repartiţia în relaţie cu modalitatea de finalizare a sarcinii Odată cu creşterea cazurilor cu malformaţii a crescut şi rata diagnosticului fapt evidenţiat prin creşterea constantă a cazurilor cu avort terapeutic (fig. 6).

6. Distribuţia cazurilor în relaţie cu tipul de anomalie congenitală. Anomaliile au variat de la minore la incompatibile cu viaţa. *Anomalii izolate* s-au înregistrat la 2032 (91,9%) din cazuri, cele mai frecvente fiind cele cardiace, genito-urinare şi scheletice. În 174 cazuri diagnosticul a fost sindrom plurimalformativ. S-au înregistrat 178 malformaţii de sistem nervos central, 640 malformaţii de cord, 59 toracice şi pulmonare, 125 de tub digestiv şi perete abdominal, 419 de aparat genito-urinar, 326 ale membrelor şi scheletului, 153 ale feţei, 174 cazuri cu sindrom plurimalformativ şi 152 de sindroame genetice (fig. 7).

7. Decesele înregistrate la copiii cu anomalii congenitale. În perioada 2001-2010, au decedat 185 copii (9,5%) din totalul de 2211 de cazuri cu malformaţii.

Dintre aceştia, 13% prezentau anomalii ale SNC, 53.5% prezentau anomalii cardiace, 3.8% malformaţii toracice şi pulmonare, 2.7% malformaţii de tub digestiv şi perete abdominal, 7% malformaţii genito-urinare, 3.2% malformaţii ale membrelor şi scheletului, 2.2% malformaţii ale feţei, 4.9% sindroame genetice, 23.3% sindroame plurimalformative şi 2.7% alte tipuri de malformaţii (fig. 9).

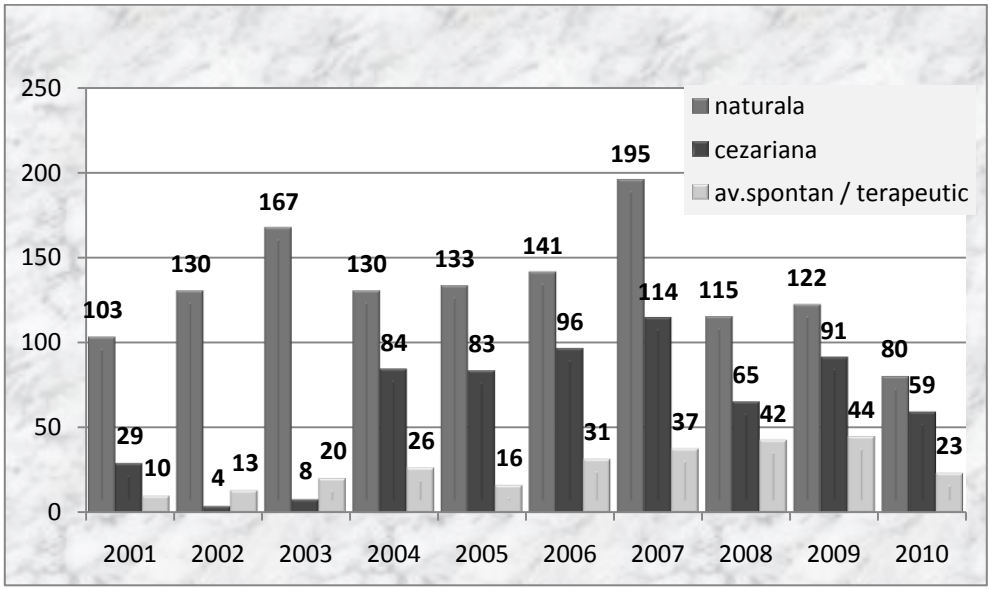

Fig. 6. Structura lotului după modul de finalizare a sarcinii pe ani de studiu

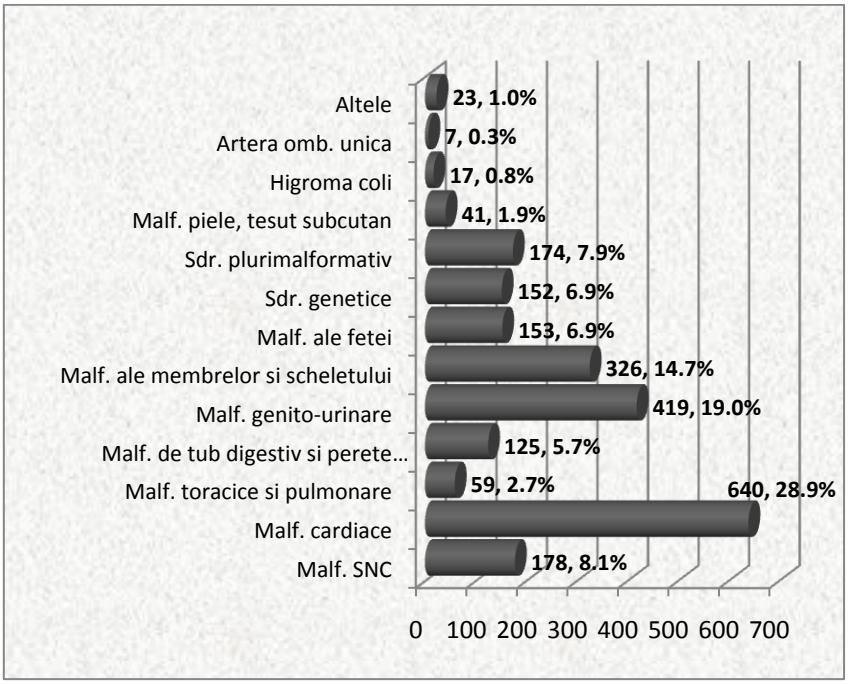

Fig. 7. Prevalenta principalelor grupe de malformaţii incluse în studiu

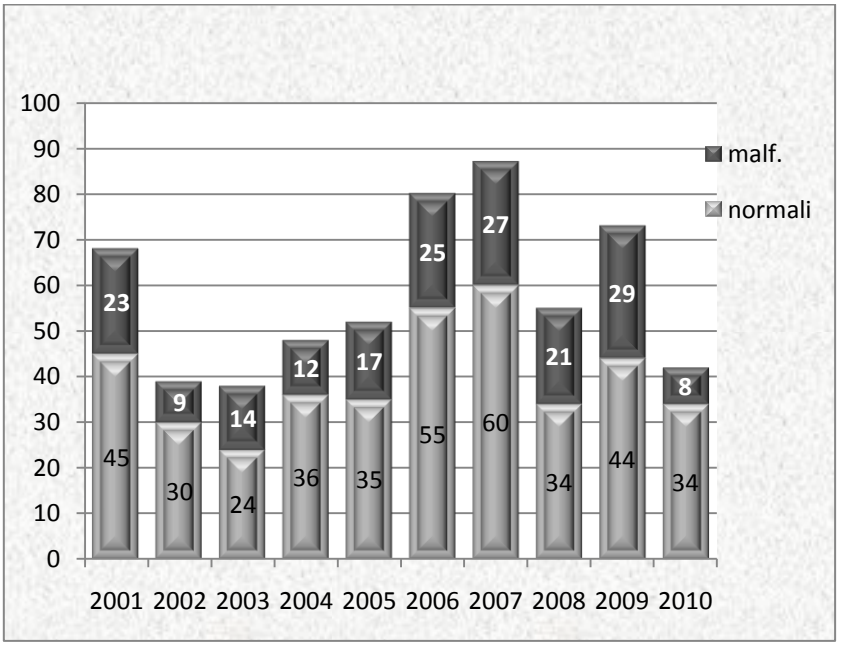

Fig. 8. Diagrama reflectă raportul între decesele neonatale şi decesele prin malformaţii comparativ pe anii 2001-2010.

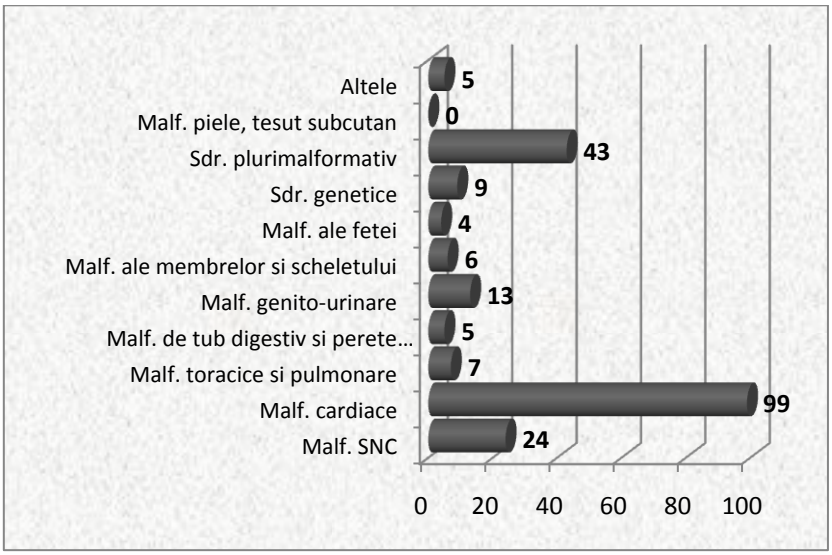

Fig. 9. Distribuţia deceselor neonatale pe categorii de malformaţii. Se observă numărul ridicat de decese la cazurile cu malformaţii cardiace.

CONCLUZII

Malformaţiile congenitale reprezintă una din principalele cauze de mortalitate la nou-născuţi. Singura modalitate de reducere a incidenţei lor rămâne dispensarizarea corectă a sarcinilor şi creşterea calităţii diagnosticului prenatal (7). În România, utilizarea tehnicilor avansate de diagnostic prenatal este limitată numai în centre specializate, drept urmare, un număr important de cazuri nu sunt diagnosticate precoce. Acest studiu subliniază importanţa unei evaluări responsabile a sănătăţii fătului, astfel încât să nu mai existe surpriza descoperirii unor anomalii fetale la naştere.

MATHEMATICAL MODELLING OF DRUG ADDICTION (Abstract). **Aim:** To describe and assess the phenomenon of drug addiction by the use of a system of linear differential equations. **Material and methods:** For analytical purposes, the study population (1020 individuals) was divided into three groups: likely to use drugs, drug users, and recovered (S-D model). **Results:** The number of individuals likely to use drugs decreases with the increase in the number of infected ones; thus, in about 10 days, the number of infected individuals matches the number of those likely to use drugs. If the global parameters of the study model are changed, a more rapid increase in the number of infected individuals is noticed. Also noticed is the fact that the number of recoveries is likely to decrease with the increase in the number of infected individuals. **Conclusions:** Although numerical techniques are often preferable, the analytical ones have some advantages. Thus, an analytical approach may provide a deeper understanding of the mechanism of a given phenomenon, so it is more convenient to describe the state variables in terms of parameters than in terms of numerical approximation. To assess to role of hazard and uncertain associations in the future statistical methods will be used. **Key words:** DRUG ADDICTION, MATHEMATICAL MODEL

Un avantaj al modelării matematice a dependenței de droguri îl constituie claritatea şi precizia formulării matematice. Un model ce utilizează ecuații diferențiale, integrale sau funcții diferențiale nu este ambiguu sau vag. Desigur, parametrii trebuiesc definiți precis şi fiecare termen al ecuațiilor trebuie explicat în termenii mecanismului, dar rezultatul modelului este o exprimare clară a principiilor de bază implicate. Odată ce formularea matematică este completă există mai multe tehnici matematice pentru determinarea limitelor, echilibrului, soluțiilor periodice şi stabilității lor globale. Mai mult informații cu privire la model pot fi obținute prin simulări numerice ale ecuațiilor. Analiza matematică şi simulările computerizate pot să identifice combinații importante ale parametrilor şi aspecte esențiale sau variabile ale modelului respectiv. Pentru a alege şi utiliza eficient modelul epidemiologic pentru o boală specifică trebuie să înțelegem comportamentul formulărilor disponibile şi a celor particulare. Singurele date disponibile sunt din grupurile de consumatori deja descoperiti sau din incidența endemică. Din păcate aceste date nu sunt complete deoarece multe cazuri nu sunt raportate. Deoarece de multe ori nu există date concrete,

simulările computerizate trebuie utilizate pentru a elabora teorii experimentale utilizând diferite valori ale parametrilor.

MATERIAL ŞI METODĂ

În formularea unui model matematic pentru o dependentă de un drog este necesară determinarea factorilor ce trebuie incluşi sau omişi. Modelele simple au avantajul că sunt formate din mai puţini parametri dar au dezavantajul că sunt mai puţin realiste. Modelele mai complexe pot fi mai realiste dar pot conţine mai mulţi parametri pentru care nu pot fi obţinute valori estimative. Este necesară luarea unor decizii în formularea modelului astfel încât acesta să fie cât mai simplu posibil şi cât mai adecvat problemelor considerate. Cea mai dificilă etapă în modelare este găsirea combinaţiei perfecte între datele existente, întrebările de interes şi modelul matematic ce conduce la răspunsuri. Se poate crea un model în care se considera au considerat o populaţie fixă împărţită în trei compartimente: susceptibili de a consuma droguri **S(t),** consumatori **D(t)** şi recuperaţi **R(t**). Compartimentele folosite în acest model definesc trei clase:

- **S(t**) reprezintă numărul indivizilor ce nu au consumat droguri la momentul de timp *t* sau sunt susceptibili pentru a consuma un drog specific;
- **D(t)** reprezintă numărul indivizilor ce consuma regulat droguri şi care au capacitatea de a atrage noi indivizi (dacă sunt considerati consumatori de risc mare) în rândul populaţiei susceptibile;
- **R(t)** reprezintă compartimentul din care fac parte indivizi ce au consumat droguri şi s-au recuperat. Aceştia nu mai sunt pasibili de a consuma droguri sau de a atrage noi consumatori.
- Numărul reproductiv de bază R_0 este definit ca fiind numărul mediu de consumatori atraşi în grup (consumatori de droguri usoare) de indivizii care consumă regulat droguri într-o populaţie complet susceptibilă. Reţinem faptul că R_0 este denumit şi raţia reproductivă de bază. Numărul de contacte **e** este definit ca fiind numărul mediu de contacte produse de un consumator regulat pe întreaga perioadă studiată. Numărul de înlocuiri **R** este definit ca find numărul mediu de consumatori atraşi în grup (consumatori de droguri uşoare) de indivizii care consumă regulat droguri de-a lungul perioadei studiate. Parametrul **R** se modifică în funcţie de timpul **t** odată cu evoluţia dependenţei de droguri după apariţia unui consumator în grupul studiat.Modelul propus şi dezvoltat în această lucrare include un sistem de ecuaţii diferenţiale liniare. Principial, rezolvarea poate fi analitică, ca în cazurile foarte simple,sau numerică, în cazurile complexe, astfel încât să se obţină o parametrizare cât mai apropiată de modelul real, în condiţii rezonabile de resurse de calcul şi timp.

Pentru o evaluare analitică să presupunem un model compartimental (1), de tip S-D pentru o populaţie constantă, unul din cele mai simple modele. Considerăm condiţiile iniţiale de forma:

$$\begin{cases} S(0) = S_0 \\ D(0) = D_0 \end{cases}$$

Deoarece populaţia grupului studiat ramâne constantă, vom avea:

$$\begin{cases} S(t) + D(t) = S_0 + D_0, \forall t \in \Re \\ S_0 = n, D_0 = 1 \end{cases}$$

Legea conservării masei, exprimată prima dată de Guldberg în 1864 postulează că "rata" unei reacţii chimice este direct proporţională cu produsul concentraţiei efective a fiecărei molecule participante. Conform acestei legii, susceptibilii devin

consumatori la o rată proporţională cu produsul mărimii celor două populaţii. Deci, dacă $b > 0$ reprezintă constanta de contact, atunci $bS(t)D(t)$ este numărul de susceptibili deveniţi consumatori pe unitatea de timp. Astfel putem scrie:

$$\begin{cases} \dfrac{dS}{dt} = -bS(t)D(t) \\ \dfrac{dD}{dt} = bS(t)D(t) \end{cases},$$

$$\begin{cases} S(t) > 0, D(t) > 0, b > 0 \\ \dfrac{dS}{dt} \le 0, S(t) descrescatoare \\ \dfrac{dD}{dt} \le 0, S(t) descrescatoare \end{cases}$$

Fiind dat b>0 şi $D(t) > 0$ pentru toţi t, sistemul de ecuaţii atinge echilibrul dacă şi numai dacă : S(t) = 0. Atunci epidemia se opreşte şi toţi susceptibilii devin consumatori. Ecuaţiile pot fi analizate analitic. Se obţine

$$\begin{cases} \dfrac{dS}{dt} = -bS[(n+1) - S] \\ S(t) = \dfrac{(n+1)e^{-Cbt(n+1)}}{1 - e^{-Cbt(n+1)}} \end{cases}$$

Impunând condiţiile iniţiale anterioare, obţinem soluţia generală:

$$S(t) = \frac{n(n+1)e^{b(n+1)t}}{n + e^{b(n+1)t}} .$$

REZULTATE

Abordările de rezolvare numerică sunt variate: ecuaţii cu diferenţe, metode Monte Carlo şi Runge-Kutta, metoda lui Galerkin în ecuaţii integro-diferenţiale pentru modelele bazate pe difuzie. Modelele compartimentale pentru dependenţă stochastică sunt în mod obişnuit inatacabile matematic, când sunt studiate prin metode numerice tradiţionale. Ecuaţiile diferenţiale din modelele compartimentale sunt transformate în ecuaţii cu diferenţe cu pas finit, pentru calcule care au fost implementate în Java . Alte metode numerice implică calculul numeric al unor integrale prin metode aproximative. Pasul de integrare, şi metoda numerică de integrare aleasă va determina efortul computaţional şi precizia de aproximare faţă de un calcul analitic. În modelarea infecţiilor şi dependentei de droguri au fost propuse tehnici şi algoritmi care includ curbe statistice de aproximare, curbe de extrapolare statistice şi modele dinamice compartimentale. Unele lucrări tratează aspectul haotic al sistemelor dinamice şi ca atare sunt analizate periodicitatea, atractorii haotici. Deşi tehnicile numerice sunt de multe ori preferabile, în obţinerea soluţiilor pentru aceste sisteme dinamice, soluţiile analitice au şi avantaje. De exemplu, o abordare analitică, poate furniza o mai profundă înţelegere asupra mecanismului dependentei, şi deci este mai convenabil să descriem variabilele de stare în termen de parametri, decât o aproximare numerică.

$$\begin{cases} \dfrac{dS}{dt} = -bS[(n+1) - S] \\ S(t) = \dfrac{(n+1)e^{-Cbt(n+1)}}{1 - e^{-Cbt(n+1)}} \end{cases}$$

Modelul clasic dependent de timp este alcătuit din trei ecuaţii diferenţiale ordinare, iar în modelul studiat ,grupul studiat este dependent atât de timp cât şi de spaţiu, generând un sistem de ecuaţii neliniare ce trebuie rezolvat pentru fiecare interval de timp.

Având în vedere o populaţie fixă de 1020 persoane, se observă că numărul persoanelor susceptibile scade odată cu creşterea numărului persoanelor infecţioase astfel încât în aproximativ zece zile numărul celor infectaţi, respectiv al susceptibililor are aceeaşi valoare (fig.1).

Dacă modificăm parametrii globali ca-

racteristici modelului S-D, se observă o creştere mai rapidă a indivizilor infecţioşi, corespunzător unui punct de echilibru raportat la curbele S/I mai mic (fig.2).

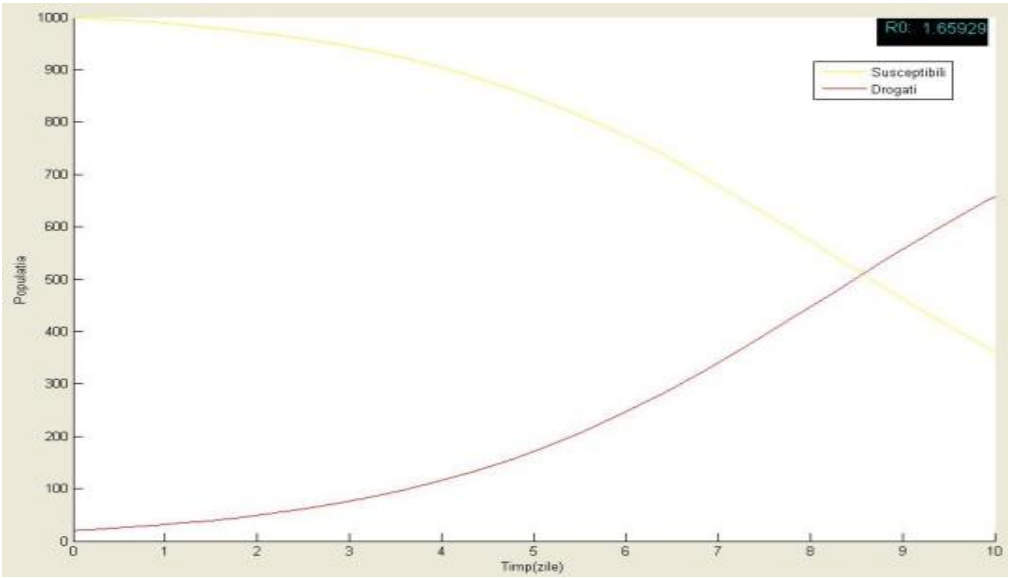

Fig. 1. Simularea soluției pentru n=1020,b=5

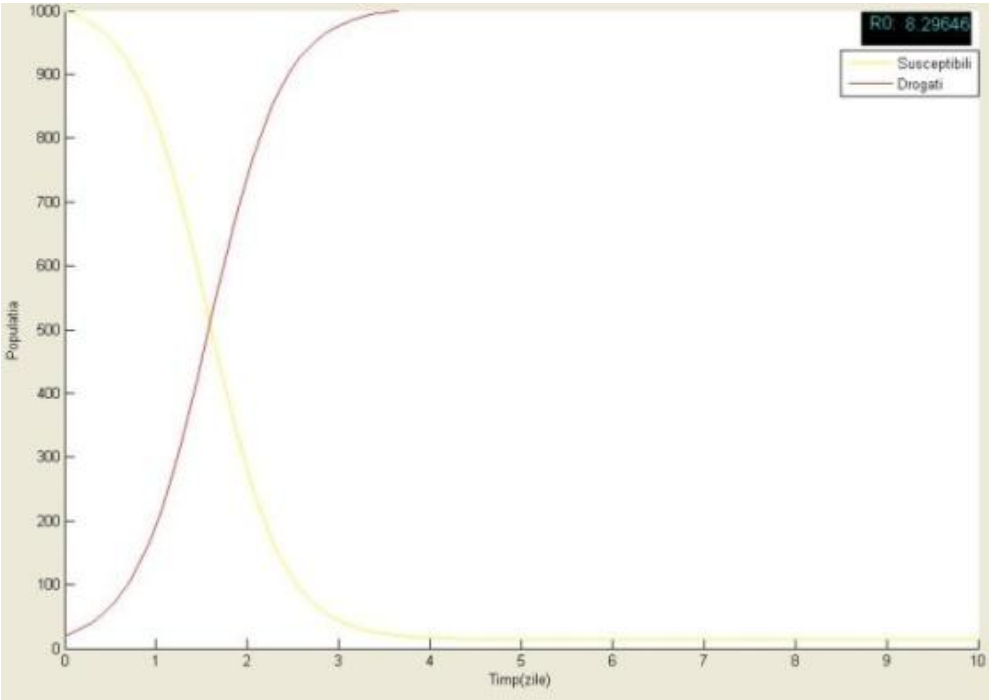

Fig. 2. Simularea soluției pentru n=1020,b=4

De asemenea se observă că o variație mare a perioadei infecțioase (de la trei la zece zile) determină o variație proporțională a numărului reproductiv de bază. Un număr mic de contacte a indivizilor cu grupul studiat de consumatori , păstrând aceleaşi condiţii pentru perioada studiată , va conduce la o creştere în timp mai lentă a numarului de consumatori concomitent cu o descreştere lentă a susceptibililor, cu un maxim al indivizilor recuperați.

Mecanismul de dinamică a dependenței în cadrul unui grup poate fi studiată cu ajutorul metodei Newton şi implementată în Matlab. Grupul se va mişca în spațiu datorită unor multitudini de nevoi, tendința lor fiind de dispersie sau de grupare. Dispersia are un caracter aleator. Dacă grupul şi durata de timp sunt suficient de mari atunci modelarea dispersiei are la bază principiile legii de deplasare a lui Fick. Modelul de dispersie în cazul S-D este de forma (2):

$$\begin{cases} \dfrac{\partial S}{\partial t} = -aSD, S(x,0) = S_0, 0 \le x \le L \\ \dfrac{\partial D}{\partial t} = aSD - bD + U\dfrac{\partial^2 D}{\partial x^2}, D(x,0) = D_0 \\ \dfrac{\partial D}{\partial t}(0,t) = \dfrac{\partial D}{\partial x}(L,t) = 0 \end{cases}$$

Pentru a rezolva ecuația diferențială caracteristică populației consumatoare de droguri, ce are în componența sa o variație unidirecțională, trebuie să impunem condiții la limită specifice:

$$\frac{\partial D}{\partial x}(0,t) = \frac{\partial D}{\partial t}(L,t) = 0$$

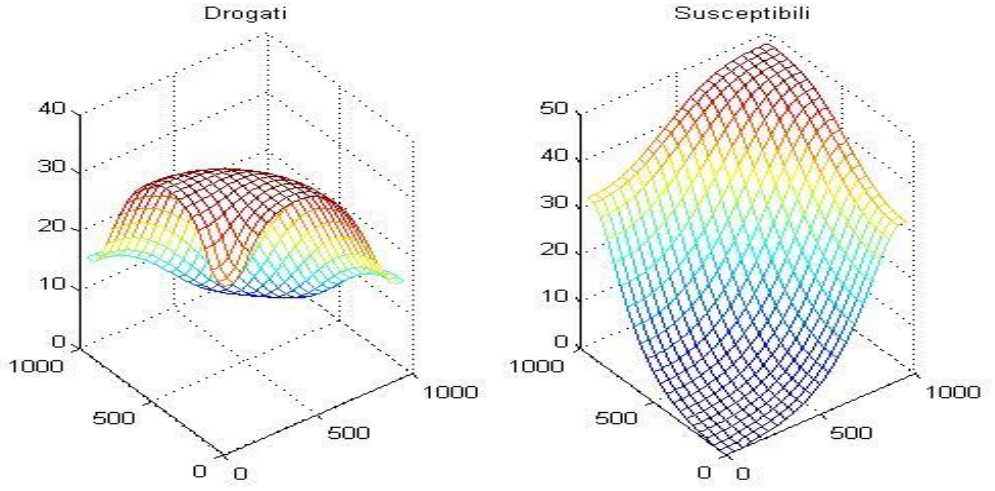

Fig. 3. Aproximarea numerică a soluției în cazul unidimensional

Modelul S-D poate fi modificat în două moduri (3). Un prim mod este să presupunem că cei care consumă droguri nu se recuperează şi în cele din urmă părăsesc grupul, cu o rată –bD.

Al doilea mod presupune faptul că populația grupului de consumatori este dispersată în două direcții potrivit legii lui Fick iar populația susceptibilă de a consuma droguri nu se dispersează.

Astfel rezultă că populația este dependentă atât de timp cât şi de spațiu în două

direcții, cu valori de concentrație S(x,y,t)și D(x,y,t), conform relațiilor (4) :

$$\begin{cases} \dfrac{\partial S}{\partial t} = -aSD, D(x,y,0) = D_0 \\ \dfrac{\partial D}{\partial t} = aSD - bD + U\dfrac{\partial^2 D}{\partial x^2} + U\dfrac{\partial^2 D}{\partial y^2} \\ \dfrac{\partial D}{\partial x}(0,y,t) = \dfrac{\partial D}{\partial x}(L,y,t) \\ S(x,y,0) = S_0, 0 \le x, y \le L, \\ \dfrac{\partial D}{\partial x}(x,0,t) = \dfrac{\partial D}{\partial y}(x,L,t) \end{cases}$$

Prin discretizarea ecuațiilor sistemului, vom obține o aproximare numerică a soluției de forma:

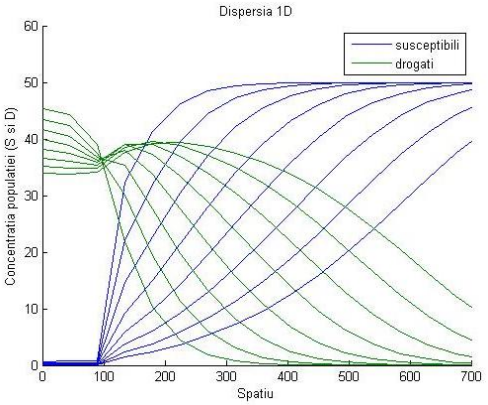

Fig. 4. Aproximarea numerică a soluției în cazul bidimensional

CONCLUZII

Metodele matematice şi informatice au devenit unelte importante în analiza şi controlul consumului de droguri. Parteneriatul între informaticieni, matematicieni, bioingineri, experții în sănătate publică şi biologi este extrem de importantă în lupta împotriva acestui flagel. În modelul prezentat în acest articol am considerat populația constantă. Această presupunere este rezonabilă, dacă grupul de consumatori devine destul de mare în mai puțin de un an. Este de asemenea o presupunere rezonabilă, în modelarea consumului de droguri de-a lungul mai multor ani ca numărul de noi consumatori care intră în grupul studiat să compenseze numărul celor care renunță la droguri. Dacă însă această balanță nu este realizată, atunci mărimea populației este o funcție de timp. Modelarea este crucială în studiul fenomenului de drogodependență deoarece în cele mai multe cazuri nu se pot realiza experimente. Pentru a evalua rolul hazardului şi a asocierilor incerte ,în viitor vom utiliza metode statistice. Rolul acestora devine mult mai complicat cu trecerea timpului datorită existenței unui volum mare de informații şi dezvoltarea unor noi tehnici şi metode computaționale mult mai performante.

RP-HPLC ANALYSIS METHOD OF BISOPROLOL FUMARATE IN A NEW TABLET FORMULATION (Abstract): **Aim:** Development of a new HPLC method for the quantitative determination of bisoprolol fumarate in a novel sustained release tablet formulation. **Material and methods:** The sustained release matrix tablets with bisoprolol fumarate were formulated using an innovative combination of hydroxypropyl methylcellulose and Precirol ATO5 as excipients. The HPLC separation was done using an Agilent Eclipse XDB-C18 column (150 mm × 4.6 mm, 5 µm) and a mobile phase consisting of acetonitrile 10 mM and pH 4.5 phosphate buffer solution (10:90, v/v) at a flow rate of 1.0 mL/min. The method was validated according to ICH guidelines in terms of accuracy, precision, linearity and robustness. **Results:** Bisoprolol fumarate was separated in less than 4 minutes with good resolution and without any tailing effect or excipient interference. The limit of detection and the limit of quantification were 2.79 and 3.07 µg/mL, respectively. The relative standard deviation evaluated for the precision of the method was lower than 1%. **Conclusions:** The HPLC method developed for the determination of bisoprolol fumarate in a novel sustained release tablet formulation was specific and simple and it could also be used for *in vitro* studies.
Keywords: HPLC METHOD, BISOPROLOL FUMARATE, PRECIROL, HYDROXYPROPYL METHYLCELLULOSE, NEW TABLET FORMULATIONS.

Hypertension continues to be one of the leading causes of death in the world. The management of hypertension requires long-term treatment that may result in poor patient compliance with conventional dosage forms due to greater frequency of drug administration (1). For this disease the most suitable administration route is the oral route. The advantages of oral administration and oral dosage forms are convenience, ease of use and lower costs.

Bisoprolol fumarate (BF) is a synthetic β_1-selective adrenoceptor blocking agent used extensively in the management of hypertension, angina pectoris, cardiac arrhythmias and myocardial infarction. It may be used alone or in combination with other antihypertensive agents, particularly thiazide diuretics (2, 3). A number of factors might affect the pharmacokinetic profile of BF and thereby contribute to the changes in therapeutic efficacy or modify

the adverse events profile. A quick and efficient way to eliminate these problems is the development of an appropriate dosage form in order to improve patient compliance. The release rate of BF, a highly water-soluble drug can be modulated using hydroxypropyl methylcellulose and Precirol ATO5 as excipients (4, 5, 6).

In order to increase the bioavailability of a drug, one of the options found in the arsenal of formulators today is melt granulation. In general, melt granulation is done by melting an appropriate polymer (Precirol) and then homogenizing the active ingredient and other formulation components into the melt (4). The aim of the procedure is the homogeneous distribution of the active ingredient in the resulting solid, which can be processed further into a solid dosage form. The advantage of melt granulation technique in comparison to conventional granulation is that no water or organic solvents are needed. Because there is no drying step, the process is less time consuming and uses less energy than wet granulation (5).

Over the last decade, high performance liquid chromatography (HPLC) has proven to be the predominant technology used in pharmaceutical laboratories worldwide in order to analyze various drug substances.

The aim of the study was the development and validation of a Reversed Phase-High Performance Liquid Chromatography (RP-HPLC) method for the determination of BF, formulated into new oral tablets with modified release. Thorough analysis of specialized literature revealed that there were numerous determination methods of bisoprolol in bulk, tablet dosage forms and biological samples, such as HPLC (7, 8), wave voltammetry (9, 10), UV-VIs spectrophotometry (11, 12), LC-MS/MS (13, 14). The reported methods are sensitive, but they are quite complicated and time consuming, thus unsuitable for routine analysis, and require expensive or sophisticated instruments.

MATERIAL AND METHODS

The substances used were: bisoprolol fumarate - 99.97 % reference substance (Unichem Laboratories LTD India), HPLC-grade acetonitrile (Merck Germany), hydrogen peroxide, ortho-phosphoric acid (Chemical Company Romania), sodium hydroxide, hydrochloric acid (Merck Germany). All chemicals and solvents used in the assay procedures were of analytical reagent grade.

Apparatus. An Agilent Technologies 1100 High Performance Liquid Chromatograph equipped with Diode Array Detector, a Kern 770 analytical balance and a Cole Parmer ultrasonic bath were used.

Preparation of modified release tablets. The 20 mg bisoprolol fumarate modified release matrix tablets had been formulated previously using an innovative combination of hydroxypropyl methylcellulose and Precirol ATO5 as excipients through melt granulation technique (4, 6).

Chromatographic conditions.The chromatographic separation of bisoprolol was performed using isocratic elution on an Agilent Eclipse XDB-C18 reverse phase stainless steel column (150 mm x 4.6 mm, 5 µm). The temperature of the column and auto sampler was maintained constant at 25°C. A 50 µL sample loop injector was used. The detection was done spectrophotometrically at 227 nm. The mobile phase was a mixture of acetonitrile and pH 4.5 phosphate buffer solution (10:90, v/v) at a flow rate of 1 mL/min

Preparation of stock and standard solutions: A 100 µg/mL BF stock solution was prepared using Milli-Q water. Aliquots of

the stock solutions were diluted using mobile phase to yield BF standard solutions in the concentration range 5-80 µg/mL.

Procedure for quantitative determination of BF from the original 20 mg tablets: 20 tablets were accurately weighed, crushed and finely powdered. An amount of powder equivalent to 10 mg BF was weighed and transferred into a 50 mL volumetric flask with methanol and ultrasonicated for 15 minutes. The solutions were filtered and further diluted using mobile phase to achieve the final concentration of 50 µg/mL BF.

The described method has been validated for the assay of BF according to ICH guidelines (15).

System suitability test of the HPLC system was performed through six replicate injections of BF standard solution. The capacity factor, tailing factor, theoretical plates and symmetry were also evaluated (16).

Linearity, LOD and LOQ: The standard solution was injected in triplicate into the HPLC system and calibration graphs were obtained by plotting the area of the peaks versus corresponding concentration levels. Regression data analysis was performed using least squares linear regression for the statistical analysis. Limit of detection (LOD) and limit of quantification (LOQ) were calculated using the equations: LOD = 3.3×standard deviation/ slope and LOQ = 10×standard deviation/slope (17, 18).

Precision study was performed to evaluate the intra- and inter-day variation. It was carried out by estimating the corresponding responses three times on the same day and on three different day (first, second and fifth day) for three different concentration levels of BF (25, 50, 75 µg/mL).

The accuracy of the analytic method was assessed as the percentage relative error. The recovery was assessed at three different concentration levels (15).

The robustness was determined by analyzing the same sample under a variety of conditions, such as: variations in flow rate, detection wavelength and mobile phase composition.

Stability studies indicated that the samples were stable while kept at room temperature and 4°C for 12 (short-term) and 48 hours (long-term).

RESULTS AND DISCUSSION

The objective of the chromatographic method was to separate the peaks of BF and its impurities in a short run time with good system suitability parameters. The majority of the ionizable pharmaceutical compounds can be very well separated on C18 (17), thus, bisoprolol could be satisfactorily separated using reversed phase chromatography. Several parameters like pH and the composition of the mobile phase, flow rate, column temperature, wavelength were examined for the optimization of HPLC analysis of bisoprolol. According to the results it was established that the optimum mobile phase was a mixture of acetonitrile and pH 4.5 phosphate buffer solution (10:90, v/v) and the retention time for the pharmaceutical substance was 3.52 min (fig. 1). Detection wavelength was established at 227 nm (fig. 2).

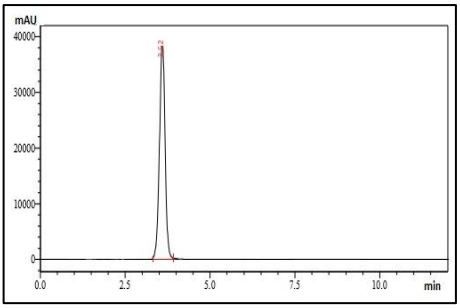

Fig. 1. Retention time

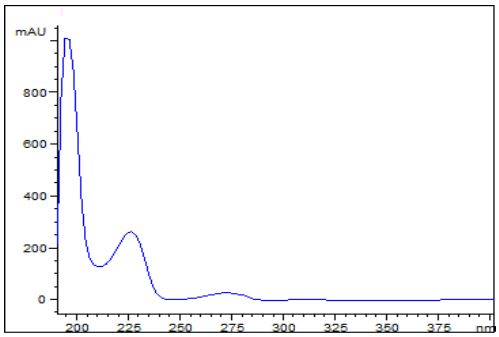

Fig. 2. BF absorption spectra

System suitability was assessed by injecting six replicates of standard solution into the apparatus. It was established through six replicate injections of standard solution that the tailing factor was less than 2.0 (18, 19) and the theoretical plates were greater than 5,000 (tab. I).

TABLE I

System suitability parameters

Capacity factor	8.02
Tailing factor	1.72
Theoretical plates	8400
Symmetry	0.91

For the linearity study the graph (fig. 3) showed a good linearity in the 5-80 µg/mL BF concentration range with a correlation coefficient (r) of 0.9994. The statistical parameters of the developed method are summarized below (tab. II).

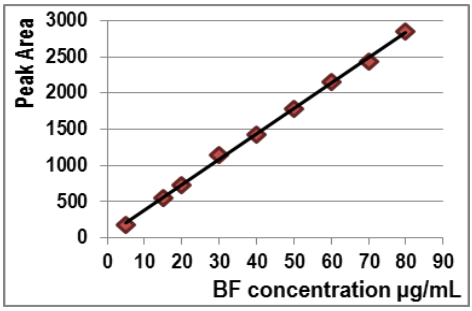

Fig. 3. Calibration curve

TABLE II

Statistical parameters

Parameter	Value
Retention time	3.52 min
Linear range	5-80 µg/mL
Limit of detection	2.79 µg/mL
Limit of quantification	3.07 µg/mL
Slope	35.096
Intercept	32.681
Correlation coefficient (r)	0.9994

Values for accuracy and precision of the method are listed in table III. All experimental results are in the range of the acceptability for accuracy (97.0-103.0%). The % RSD values found in precision study showed that the proposed method provides acceptable intra- and inter-day variations for BF determination.

TABLE III

Accuracy and precision studies

Theoretical conc. (µg/mL)	Accuracy		Precision			
			Intra-day		Inter-day	
	Mean recovered conc. of BF	Mean % recovery	Mean*±SD	% RSD	Mean*±SD	% RSD
25	24.78	99.12	24.98±0.3141	0.71	24.86±0.3051	0.75
50	50.05	100.10	50.09±0.2856	0.63	50.06±0.2924	0.59
75	75.05	100.06	75.04±0.3015	0.68	75.10±0.2963	0.72
** average concentration (µg/mL) for three determinations*						

The results of robustness study (tab. IV) showed that there were no significant changes in the chromatographic pattern when the above modifications were made in the experimental conditions, proving that the method was robust. The % RSD of bisoprolol fumarate was lower than 2.0 %.

The results of the stability studies are given the percent ratios within the acceptance range of 90-110% (tab. V).

TABLE IV
Robustness Study

Parameter	Optimized	Variations	Retention time (min)	Conclusion
Flow rate (±0.2 mL/min)	1.0 mL/min	0.8 mL/min	3.59	robust
		1.0 mL/min	3.52	robust
		1.2 mL/min	3.33	robust
Detection wavelength (±5 nm)	227 nm	223 nm	3.52	robust
		227 nm	3.52	robust
		230 nm	3.58	robust

The validated method was applied to the determination of BF in original tablet formulations. The result of the assays (n = 6) are presented in table VI. No interference of the tablet excipients was detected.

TABLE VI
Analysis of BF in developed tablets

Label claim (mg/tablet)	% found ± SD (n=6)	RSD (%)
20	100.12±0.6942	0.6879
20	100.32±0.87.52	0.8556

CONCLUSIONS

We have developed a new HPLC method with UV detection for the estimation of bisoprolol fumarate in sustained release tablets. The advantages of our method are short analysis time, a simple procedure for sample preparation, specificity, and ability to separate the drug from formulation excipients. No extraction procedure is necessary, and the mobile phase composition is quite simple to prepare and is economical. The method is suitable for routine analysis of BF in bulk or in tablet dosage forms and can be also used during *in vitro* studies.

EPIDEMIOLOGICAL AND FORENSIC MEDICAL CONSIDERATIONS REGARDING FREQUENCY AND CAUSES OF VIOLENT DEATHS IN IASI COUNTY, BETWEEN 1997-2006 (Abstract)**:** Authors present some epidemiological aspects of violent deaths in Iasi County, with certain comparisons with Romania, during the period 1997-2006. **Material and method:** The study included information collected by Institutes of Forensic Medicine at the national level. **Results**: In Romania, violent deaths registered values between 2,6 and 4,5‰, with yearly non-significant statistical differences when reported to causes of death, excepted years 2005 and 2006. Violent deaths situated Iasi County over the national level (8-11 / 2.7‰). Homicides registered 9.3‰, as compared with much more reduced values in other 12 Romanian counties, in the same period of study. **Conclusions**: Violent death in Romania and Iasi County highlighted a dependence of difficulties to carry out efficient programmes of prevention and emergency assistance. **Key words**: VIOLENT DEATH, EPIDEMIOLOGY, FORENSIC MEDICINE

Violenţa a fost şi va fi mereu parte a experienţei umane, cu un impact diferit în variate arii geografice. Anual, la nivel mondial, violenţa ucide peste un milion de oameni, îndeosebi din grupurile de vârsta 15-44 ani (1,2,3,4).

Eteroviolenţa este semnalată în istoria existenţei umane, atribuindu-i-se numeroase definiţii, între care, recent, se face referire la cea elaborată de OMS, după care: „violenţa reprezintă utilizarea intenţionată a puterii sau a forţei fizice propriu-zise sau prin ameninţare, îndreptate împotriva propriei persoane sau a alteia sau împotriva unui grup de persoane sau a unei comunităţi, care, fie are ca rezultat sau este probabilă a avea ca rezultat afectarea integrităţii fizice sau psihice, decesul, împiedicarea dezvoltării normale" (7,8).

În ciuda faptului că violenţa a fost mereu prezentă, umanitatea nu o acceptă ca fiind parte inevitabilă a condiţiei sale. Prevenţia şi combaterea violenţei se află, astăzi, în preocupările unor sisteme religioase, filosofice, juridice şi comunitare (1,2,3,7).

Lucrarea de faţă îşi propune să evidenţieze unele aspecte privind frecvenţa deceselor prin cauze violente, în judeţul Iaşi, cu unele referiri şi la situaţia din România, pentru perioada 1997-2006.

MATERIAL ŞI METODE

În studiu au fost incluse informaţiile furnizate de către Institutele de Medicină Legală şi acumulate la nivel naţional. Prelucrarea şi

TABELUL I

Evoluţia anuală a frecvenţei cazurilor de moarte violentă, în România, în perioada 2000-2006

Anul	‰	% din total decese
2000	4,5	61,3
2001	4,4	59,0
2002	4,0	57,2
2003	3,6	61,4
2004	2,8	62,1
2005	3,1	59,4
2006	2,6	63,3

interpretarea datelor s-au realizat prin metode epidemiologice şi statistico-matematice.

REZULTATE ŞI DISCUŢII

1. Aspecte din evoluţia frecvenţei cazurilor de moarte violentă în relaţie cu decesele prin cauze non-naturale. În România, în perioada 2000-2006, frecvenţa morţii violente a înregistrat valori de 2,6 la 4,5‰, iar raportat la totalul deceselor, au fost valori de 57,2 la 63,3%. În ambele aspecte, diferenţele anuale au avut o semnificaţie statistică redusă ($p < 0,05$) (tab. I).

Pentru perioada 1997-2006, moartea prin violenţă din total decese prin cauze non-naturale a înregistrat valori anuale cu diferenţe nesemnificative ($p < 0,05$) (57,4 – 61,9%), cu excepţia anilor 2005 şi 2006, când valorile au crescut la 83,1 şi 84,7%, cu o diferenţă puternic semnificativă ($p < 0,01$) (fig. 1).

Sub toate aspectele, evaluările asupra frecvenţei cazurilor de moarte violentă arată valori ridicate, explicate, cel puţin parţial, prin situaţia socio-economică, cu modificări, adesea, brutale şi creşterea ponderii unor structuri demografice cu importante dificultăţi de inserţie socială.

2. Situaţia anuală, comparativă, între România şi judeţul Iaşi, a frecvenţei deceselor prin violenţă, altele decât sinuciderile. Perioada 2000-2006 s-a remarcat, în România şi în judeţul Iaşi, prin înregistrarea unor valori ridicate ale deceselor prin violenţă, altele decât sinuciderile. Astfel, în cei 7 ani luaţi în studiu, acest tip de deces a înregistrat valori anuale de 2,7 în 2006 şi 4,5‰ în 2000 şi 2001, cu diferenţe semnificative statistic ($p < 0,05$), care se păstrează când se compară situaţia de la nivel naţional cu cea din judeţul Iaşi, unde valorile de frecvenţă au fost de 8,0 în 2006 şi 11,0 în 2000 sau 9,3‰ în 2003. Rezultatele din judeţul Iaşi pot fi explicate prin situarea acestuia într-o arie geografică unde se înregistrează importante dificultăţi socio-economice, care îşi pun amprenta negativă pe natura comportamentului uman (fig. 2).

TABELUL II

Evoluţia anuală numerică a cazurilor de moarte prin omucidere, în România, în perioada 1997-2006

Anul	Cazuri	
	Nr.	‰
1997	1047	0,47
1998	870	0,39
1999	863	0,39
2000	1024	0,46
2001	947	0,43
2002	873	0,39
2003	782	0,35
2004	617	0,28
2005	672	0,30
2006	563	0,25

3. Aspecte privind evoluţia frecvenţei omuciderilor în România şi judeţele din Moldova. În perioada 1997-2006, decesele prin omucidere au înregistrat valori relativ crescute, cu variaţii de la 0,25 – 0,28 în 2006 şi 2004 şi între 30 şi 40‰, în ceilalţi ani. S-a observat o scădere moderat semnificativă, îndeosebi în intervalul 2002-2006, dar nu poate fi vorba de o tendinţă, întrucât valorile anuale au înregistrat modificări nesemnificative ($p > 0,05$) (tab. II).

Situaţia omuciderilor raportate la 100.000 locuitori, comparativ în România şi judeţele din Moldova arată, îndeosebi pentru judeţul Iaşi, valori peste media ţării,

TABELUL III
Situaţia omuciderilor la 100.000 / loc., în România şi judeţele din Moldova, în perioada 2003-2006

Anul	România	Iaşi	Vaslui	Vrancea	Suceava	Neamț	Galați	Botoşani	Bacău
2003	3,5	9,3	5,6	4,3	4,3	3,9	6,5	3,2	7,8
2004	2,8	4,0	4,3	4,3	3,1	4,3	3,4	3,2	5,6
2005	3,1	10,1	5,2	4,0	3,5	3,5	3,7	2,8	4,3
2006	2,6	8,0	3,4	2,8	1,7	2,1	4,0	2,8	2,6

TABELUL IV
Analiza unor cauze şi circumstanţe în care s-a produs moartea violentă, în România, comparativ în anul 1998 şi 2006

Cauze şi circumstanțe	% din total cazuri de moarte violentă	
	1998	*2006*
Lovire cu un corp dur	30,3	25,8
Politraumatisme	29,3	53,4
Sinucideri	26,3	27,7
Accidente rutiere	22,2	23,3
Intoxicații	10,1	10,8
Spânzurare	6,9	19,9
Arsuri	4,3	3,4
Accidente feroviare	4,2	2,6
Sugrumare	4,2	6,1
Accidente casnice	2,9	11,7
Accidente de muncă	2,4	2,9
Electrocuții	1,7	2,0
Plăgi înțepate / tăiate	1,5	2,2
Împuşcare	1,0	0,3

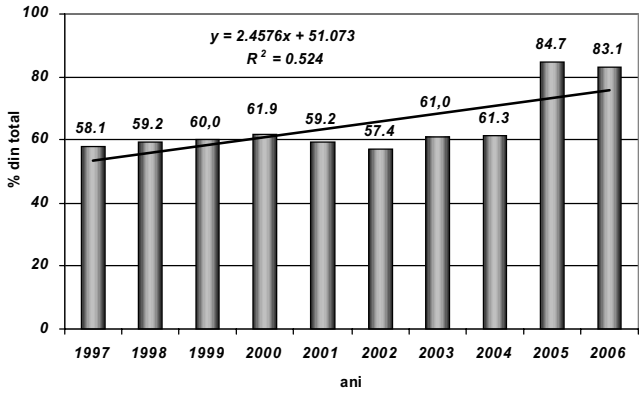

Fig. 1. Evaluări anuale ale raportului dintre moartea prin violenţă din total decese prin cauze non-naturale, în România, în perioada 1997-2006

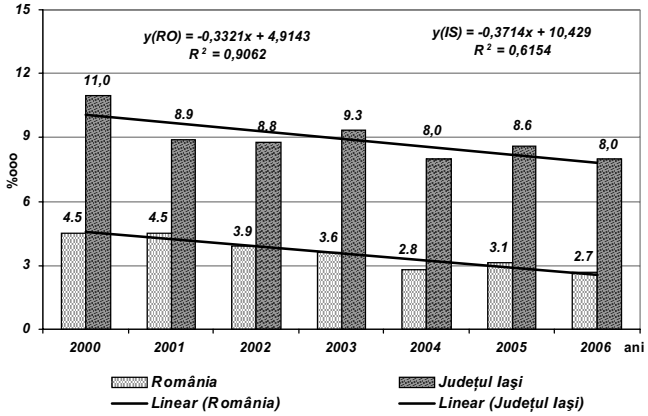

Fig. 2. Evoluţia anuală a frecvenţei deceselor prin violenţă, altele decât sinuciderile, în România şi comparativ în judeţul Iaşi, în perioada 1997-2006

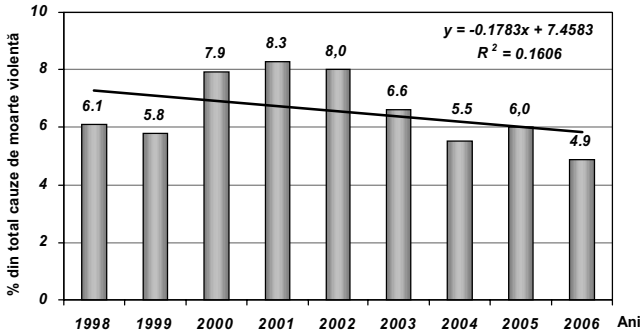

Fig. 3. Evoluţia anuală a frecvenţei cazurilor de omucideri în relaţie cu totalul cauzelor de moarte violentă, în România, în perioada 1998-2006

cu creşteri de aproximativ 3-4 ori, în intervalul 2003-2006 ($p < 0,05$). Diferenţele sunt prezente, fără această amploare, şi în celelalte judeţe din Moldova, aceste aspecte fiind concludente pentru zona geografică, unde există structuri demografice marcate de comportamente care predispun la producerea omuciderilor (tab. III, fig. 3).

Valorile frecvenţei omuciderilor, în judeţul Iaşi, comparativ cu alte 12 judeţe din România, îl situează pe acesta pe primul loc cu 9,3‰ cazuri şi între primele 6, cu valori situate peste media ţării (4,5‰) (fig. 4).

4. Aspecte privind cauzele şi circumstanţele în care s-a produs moartea violentă. Analiza comparativă, între anul 1998 şi 2006, pentru un eşantion de 12 cauze şi circumstanţe producătoare de moarte violentă, în România, a situat între primele locuri loviriile cu un corp dur (30,3, respectiv 25,8%) din total cazuri de moarte violentă, urmată de politraumatisme (29,3 / 53,4%); sinucideri (26,3 / 27,7%); accidente rutiere (22,2 / 23,3%) şi intoxicaţii (10,1 / 10,8%), urmate de celelalte cauze, cu proporţii variabile, dar mai reduse (tab. IV).

Variabilitatea de cauze şi circumstanţe evidenţiază polimorfismul acestora, dependent de multitudinea intervenţiilor umane şi, deci, de dificultăţile în a realiza programe eficiente de prevenţie şi asistenţă de urgenţă. Ca şi în cazul celorlalte aspecte care evidenţiază particularităţile condiţiilor şi circumstanţelor producerii morţii violente, factorii socio-economici, inclusiv cei educaţionali,

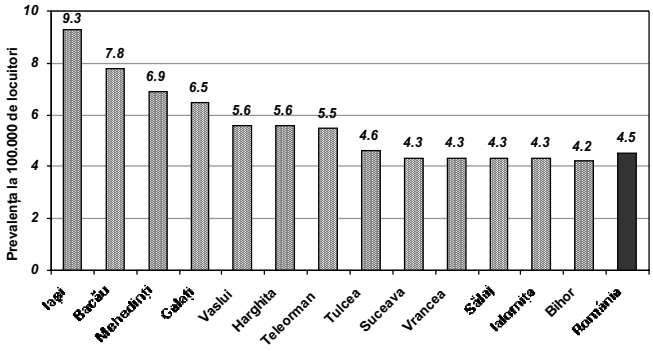

Fig. 4. Valorile frecvenţei cazurilor de omucideri în judeţul Iaşi, comparativ cu alte zone din România, în anul 2003

explică diferenţele valorilor crescute ale frecvenţei morţii violente, privite temporal şi spaţial geografic.

Din toate aceste date, rezultă necesitatea elaborării şi implementării unor măsuri complexe, cu caracter de permanenţă, cu diferenţieri pe structuri populaţionale, pe cauze şi circumstanţe implicate în determinarea morţii violente.

CONCLUZII

În România, în perioada 1997-2006, frecvenţa morţii violente a înregistrat valori de 2,6 - 4,5‰, iar, raportat la total decese prin cauze non-naturale, valorile anuale au avut diferenţe nesemnificative (57,4-61,9%), cu excepţia anilor 2005 şi 2006 (83,1-84,7%). Mortalitatea anuală, în perioada 2000-2006, a deceselor prin violenţă, comparativ, în România şi judeţul Iaşi, l-a situat pe acesta din urmă la un nivel deosebit de ridicat (2,7- 4,5 în România şi 8-11‰ în judeţul Iaşi), situaţie explicată prin dificultăţile socio-economice, cu amprentă negativă asupra naturii comportamentelor umane.

În intervalul 2003-2006, frecvenţa omuciderilor în judeţele Moldovei a situat judeţul Iaşi pe primul loc 9,3‰, la fel când situaţia a fost comparată cu alte judeţe din România. Analiza cauzelor şi circumstanţelor producătoare de moarte violentă, în România, a evidenţiat varietatea acestora, dependent de multitudinea intervenţiilor umane şi, deci, şi de dificultăţile în a realiza programe eficiente de prevenţie şi asistenţă cu caracter de urgenţă.

PHYTOCHEMICAL PROFILE AND ANTIOXIDANT ACTIVITY OF *VERBASCUM BLATTARIA* L. (Abstract): **Aim**: The HPLC-ESI-Q-TOF-MS phytochemical profile and *in vitro* antioxidant activity of extracts obtained from the aerial parts of *Verbascum blattaria* were investigated. **Material and methods:** Phytochemical screening was performed by a hyphenated LC-MS technique, whereas total phenolic content was assessed by Folin-Ciocalteu method. Antioxidant activity was evaluated using four different *in vitro* tests: hydroxyl and DPPH radicals scavenging, ferrous ion chelating and ferric ion reducing assays. **Results and discussion**: A total of 17 secondary metabolites (carboxylic acids, flavonoids, iridoids, phenylethanoids and saponins) were identified in *V. blattaria* extracts. Among the four samples, *n*-butanol extract was the most potent scavenger of the hydroxyl and DPPH radicals, with EC_{50} values of 224.14 and 591.67 µg/mL, respectively. Additionally, the same extract exhibited an EC_{50} of 193.51 µg/mL in the ferric ion reducing assay. **Conclusions**: The current work allowed concluding that *n*-butanol extract of *V. blattaria* is the most promising in relation to antioxidant potential; the *in vivo* significance of its antioxidant effects needs to be further evaluated. **Keywords**: *VERBASCUM BLATTARIA*, IRIDOIDS, ANTIOXIDANT, HYDROXYL RADICAL, LC-MS.

With more than 350 species worldwide distributed, *Verbascum* L. is the largest genus of Scrophulariaceae family (1). In the traditional folk medicine, the roots, leaves and flowers have been used since ancient times mainly as remedies for respiratory tract disorders, such as bronchitis, cough, tuberculosis or asthma (2). *Verbascum* species (mulleins) attracted researchers' attention in the past 30 years, as they were found to be a very rich source of bioactive constituents (iridoids, phenylethanoids, saponins, flavonoids) with confirmed anti-inflammatory, antioxidant, antimicrobial or cytotoxic properties (3). Despite the fact that numerous mullein species have been already scientifically approached (1), new species are continuously discovered, whilst some known ones are currently very little investigated. It is the case of *Verbascum blattaria* L. (moth mullein), for which literature is not very abundant. In one study, 11 iridoid glycosides have been identified by thin-layer chromatography (4), whereas in another one, four iridoid and flavonoid glycosides have been isolated (5). The aim of this study was

to perform the phytochemical screening of various extracts obtained from the aerial parts of *V. blattaria* using different polarity solvents and evaluate for the first time their *in vitro* antioxidant activities.

MATERIAL AND METHODS

Plant material

The aerial parts of *Verbascum blattaria* L. were collected in Răscăieți (Ștefan Vodă County, Republic of Moldova) in June 2014. The plants were dried, milled to powder and deposited in the Department of Pharmacognosy, Faculty of Pharmacy, "Grigore T. Popa" University of Medicine and Pharmacy, Iasi, Romania (voucher specimen VB2806/2014).

Extraction

Five grams of powdered plant material were subjected to ultrasound extraction for three cycles of 30 minutes each, with 50 mL of solvent. Extracts were filtered, combined and dried under reduced pressure. *n*-Hexane (HE, 0.015 g, yield: 0.15%), ethyl acetate (EAE, 0.025 g, yield: 0.26%), *n*-butanol (BE, 0.19 g, yield: 3.80%) and aqueous (AQE, 0.840 g, yield: 16.8%) extracts resulted.

HPLC-ESI-Q-TOF-MS analysis

LC-MS analysis was performed using an Agilent 1260 HPLC equipped with a G1312C binary pump, G1322A degasser, G1316A column oven, G1315 D diode array detector (DAD), G1320B autosampler and a G6530B quantum-time-of-flight-mass spectrometer (Q-TOF-MS) with an electrospray ionization (ESI) source. Separation was carried out on a Zorbax RP-18 (150 × 2.1 mm, 3.5 μm) column. The mobile phase consisted of: solvent A (0.1% formic acid in water) and solvent B (0.1% formic acid in acetonitrile). A linear gradient varying from 0% B (0 min) to 55% B (40 min) was used, at a flow rate of 0.2 mL/ min. Analyses were performed in negative ionization mode with the additional parameters: nitrogen gas flow rate 12 L/min; nebulizer pressure 40 psig; vaporizer temperature 300°C; capillary voltage 4000 V; fragmentor 140 V; skimmer 65 V; 100–1700 m/z; auto-tandem MS (MS/MS) acquisition mode; collision induced dissociation 20 eV.

Total phenolic and flavonoid contents

Total phenolic and flavonoid contents were estimated using Folin-Ciocalteu assay (6) and the method of Ozsoy *et al*. (7), respectively. Results were expressed as mg gallic acid equivalents (GAE)/g extract for total phenolics and mg catechin equivalents (CE)/g extract for flavonoids.

In vitro antioxidant assays

DPPH radical scavenging and ferric ion reducing assays were performed as described in Aprotosoaie *et al*. (8), hydroxyl radical scavenging as in Cretu *et al*. (9) and ferrous ion chelating assay as in Luca *et al*. (10). DPPH radical-scavenging activity (%) was calculated according to the following equation: % = [(absorbance of DPPH solution – absorbance of DPPH solution with sample after 5 min)/absorbance of the DPPH solution] × 100. Ferrous ion chelating and hydroxyl radical scavenging activities (%) were calculated as follows: % = [(absorbance of control − absorbance of sample)/absorbance of control] × 100.

Statistical analysis

All experiments were conducted in triplicate. The results were expressed as mean ± standard deviation (SD). Statistical analysis was performed using Student's t test; $p < 0.05$ was considered statistically significant. The efficient concentration 50 (EC_{50}) values were calculated by linear interpolation between absorbances above and below 0.5000 in ferric ion reducing assay and activities above and below 50% in all other tests.

RESULTS AND DISCUSSION

HPLC-ESI-Q-TOF-MS analysis

The four extracts of *V. blattaria* by using different polarity solvents (*n*-hexane, ethyl acetate, *n*-butanol and water) were subjected to a rapid HPLC-ESI-Q-TOF-MS analysis to systematize the information regarding their phytochemical composition. Two compounds (verbascoside and luteolin-7-*O*-glucoside) were identified by additionally injecting the corresponding commercially available standards. The other constituents were tentatively identified by comparing their MS data with those reported in the literature (11) and METLIN database (12). A total of 17 secondary metabolites were identified (fig. 1), grouped into several classes: carboxylic acids (compounds **1**–**5**), flavonoids (compounds **7** and **10**), iridoids (compounds **6**, **9**, **11**–**15**), phenylethanoids (compound **8**) and saponins (compounds **16** and **17**). Acylated derivatives of 6-*O*-rhamnosylcatalpol, such as *p*-coumaroyl acetyl 6-*O*-rhamnosylcatalpol and cinnamoyl acetyl 6-*O*-rhamnosylcatalpol, were the most abundant iridoids. This subcategory of compounds is known to be well represented in *Verbascum* species, with more than 30 congeners reported up to date (1). Moreover, verbascoside and luteolin-7-*O*-glucoside are among the most frequent constituents, being identified in almost all investigated mullein species (1). Several noteworthy qualitative differences between the four types of *V. blattaria* extracts were observed. In HE (the least polar extract) very few metabolites were identified, whereas AQE showed the highest number of polar constituents (aliphatic carboxylic acids, such as malic acid, citric acid, quinic acid). EAE and, especially, BE contained metabolites with medium polarity (including here iridoids, phenylethanoids and saponins) that are known to possess intrinsic antioxidant, cytotoxic and anti-inflammatory properties (1).

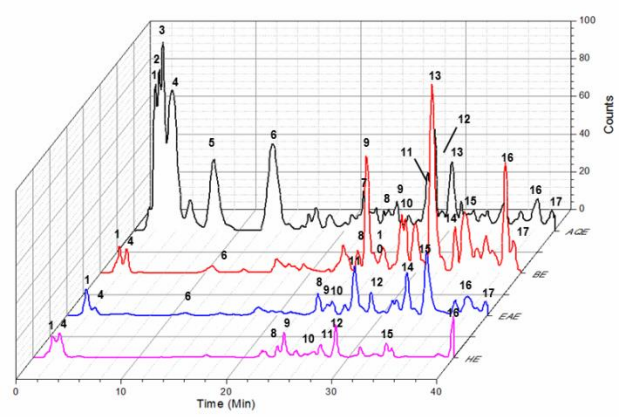

Fig. 1. Base peak chromatograms of extracts obtained from the aerial parts of *Verbasucm blattaria*. 1 – caffeic acid glucoside (Rt 1.8 min); 2 – malic acid (Rt 2.3 min); 3 – citric acid (Rt 2.6 min); 4 – quinic acid (Rt 3.2 min); 5 – hydroxyvaleric acid glucoside (Rt 5.4 min); 6 – ajugol (Rt 10.0 min); 7 – apigenin pentoside (Rt 22.2 min); 8 – verbascoside (Rt 23.2 min); 9 – *p*-coumaroyl 6-*O*-rhamnosylcatalpol (Rt 24.0 min); 10 – luteolin-7-*O*-glucoside (Rt 25.0 min); 11, 12 – *p*-coumaroyl acetyl 6-*O*-rhamnosylcatalpol isomers (Rt 27.3 and 28.9 min); 13 – di-*p*-coumaroyl 6-*O*-rhamnosylcatalpol (31.1 min); 14 – cinnamoyl acetyl 6-*O*-hamnosylcatalpol (Rt 32.6 min); 15 – *p*-coumaroyl diacetyl 6-*O*-rhamnosylcatalpol (33.2 min); 16 – mulleinsaponin IV (Rt 38.4 min); 17 – ilwensisaponin C (Rt 39.4 min).

Total phenolic and flavonoid contents

Total phenolic content of *V. blattaria* extracts varied between 1.53±0.21 mg GAE/g in HE and 52.41±1.13 mg GAE/g in BE. No significant differences were observed between total phenolic content in EAE and AQE (tab. I). These values were very similar to those reported in the aqueous extracts of *V. phlomoides* (51.3±0.3 mg GAE/g) and *V. thapsus* (52.3±0.3 mg GAE/g), but lower than those found in various extracts of other *Verbascum* species (74.1±0.4 –135.0±2.1 mg GAE/g) (13).

TABLE I

Total phenolic and flavonoid contents of extracts obtained from the aerial parts of *V. blattaria*

Sample	TPC (mg GAE/g extract)	TFC (mg CE/g extract)
HE	1.53±0.21[a]	–
EAE	43.90±1.86[b]	11.11±0.21[a]
BE	52.41±1.13[c]	26.34±0.32[b]
AQE	43.88±1.18[b]	9.66±0.38[c]

AQE aqueous extract; BE *n*-butanol extract; CE catechin equivalents; EAE ethyl acetate extract; GAE gallic acid equivalents; HE *n*-hexane extract; values in each row with different superscripts are significantly different ($p < 0.05$).

With regard to flavonoid content, BE possessed the highest amount (26.34±0.32 mg CE/g), whereas EAE and AQE had contents 2.3–2.8 times lower No flavonoids were quantified in HE (tab. I). Mihailovic *et al* (13) reported a flavonoid content of 10.2±0.2–53.4±0.2 mg rutin equivalents/g in *V. nigrum*, *V. phlomides* and *V. thapsus*, whilst Karamian and Ghasemlou (14) showed that *V. nudicaule*, *V. sinuatuam* and *V. speciosum* contained 4.83±0.13–5.77±0.23 mg rutin equivalents/g.

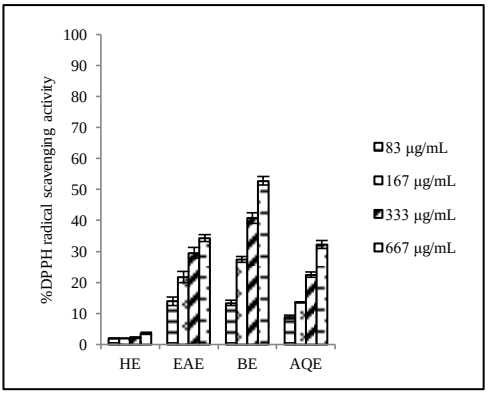

Fig. 2. DPPH free radical scavenging activity of extracts obtained from the aerial parts of *V. blattaria*

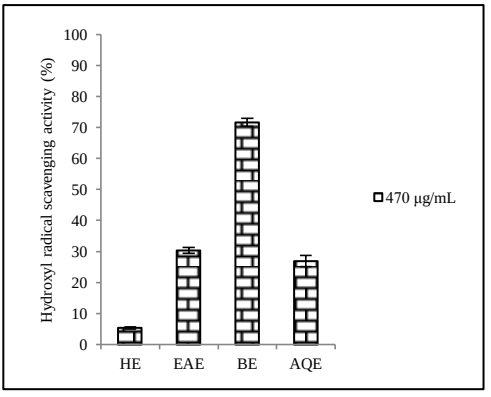

Fig. 3. Hydroxyl radical scavenging activity of extracts obtained from the aerial parts of *V. blattaria*

DPPH free radical scavenging activity

V. blattaria extracts showed moderate scavenging activity against DPPH radical. At the highest tested concentration (667 µg/mL), EAE, BE and AQE scavenged 34.29±1.07%, 52.78±1.31% and 32.25± 1.28% of the radical, respectively. At the same concentration, HE had very weak scavenging effects (3.59±0.28%). With respect to the EC_{50} values, BE was the most active extract (591.67±25.58 µg/mL). This activity was, however, lower than that reported in literature for the methanolic and aqueous extracts of *V. thaspsus*, *V. phlomoides* and *V. nigrum* (EC_{50} = 60.7±1.7–257.0±4.6 µg/mL) (13).

Hydroxyl radical scavenging activity

Among the four extracts of *V. blattaria*, BE was the most active, with a hydroxyl scavenging activity of 71.61±1.34% at 470 µg/mL. At the same concentration, EAE and AQE were two times less efficient (31.22±0.93% and 26.91±1.81%, respectively), whereas HE was almost inactive (Fig. 3). EC_{50} value was possible to be subtracted only for BE (224.14±10.35 µg/mL). As compared to the *n*-butanol extract of *V. ovalifolium* with a reported EC_{50} of 490.49±2.57 µg/mL (11), BE of *V. blattaria* was a more efficient hydroxyl radical scavenger. However, the methanolic and water extracts of *V. thapsus*, *V. nigrum* and *V. phlomoides* generated lower EC_{50} values (3.3±0.7–171.6±5.0 µg/mL) (13).

Ferrous ion chelating activity

The extracts obtained from *V. blattaria* exhibited poor ferrous ion chelating effects. At the concentration of 8 mg/mL, the most active extract, BE (11.69±1.29%), was followed by EAE (10.56±0.94%), AQE (8.17±0.77%) and HE (2.37±0.29%) (Fig. 4). Using a slightly different experimental protocol, Karamian and Ghasemlou (14) found that the methanolic extracts of *V. nudicaule*, *V. sinuatum* and *V. speciosum* exhibited chelating activities of 19.06±8.80%, 14.44±4.89% and 5.42± 0.72%, respectively, at 1 mg/mL.

Ferric ion reducing activity

EAE and BE catalyzed the reduction of iron (III) to iron (II) in a linear dose-dependent manner, the absorbance (700 nm) increasing from 0.1725±0.0106 and 0.3153±0.0114, respectively, at 30 µg/mL, to 0.5949±0.0076 and 1.0611±0.0306, respectively, at 240 µg/mL (R^2=0.9999 and 0.9945, respectively). At the highest tested concentration, HE and AQE showed an absorbance of only 0.1633±0.0170 and 0.1344±0.0100, respectively (Fig. 5). Therefore, EC_{50} values were calculated only for EAE (EC_{50}=193.51±6.68 µg/mL) and BE (EC_{50}=73.59±3.48 µg/mL). These values suggest that BE was approximately 2.5-fold more efficient in reducing iron (III). At a similar concentration (250 µg/mL), the methanolic extract of *V. thapsus* showed an absorbance of 1.162 at 700 nm, very close to that of BE (13). However, as compared to *n*-butanol extract of *V. ovalifolium* with a reported EC_{50} of 15.56±0.47 µg/mL (11), BE of *V. blattaria* was 4.5 times less active.

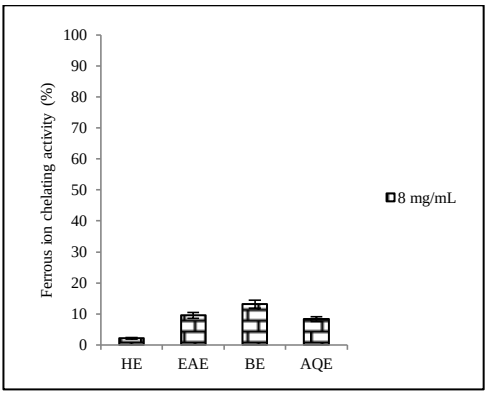

Fig. 4. Ferrous ion chelating activity of extracts obtained from the aerial parts of *V. blattaria*

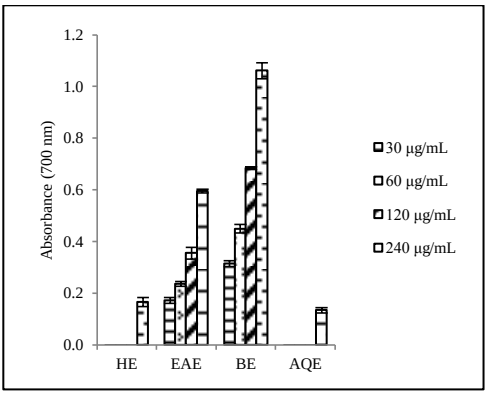

Fig. 5. Ferric ion reducing activity of extracts obtained from the aerial parts of *V. blattaria*

CONCLUSIONS

In the current work, four extracts obtained from the aerial parts of *V. blattaria* by extraction with different polarity solvents were phytochemically screened by HPLC-ESI-Q-TOF-MS. Base peak chromatograms, together with evaluation of total phenolic and flavonoid contents, suggested that ethyl acetate, *n*-butanol and aqueous extracts contained the main metabolites responsible for the potential health benefits of this species. Indeed, *in vitro* antioxidant activity allowed concluding that *n*-butanol was the most potent DPPH and hydroxyl radicals scavenger, as well as the most efficient ferric ion reducing agent. In most tests, ethyl acetate, and aqueous extracts exhibited similar antioxidant activities, but significantly lower. Therefore, solvents with medium polarities, such as *n*-butanol, might have the ability to extract a higher number of mullein bioactive constituents, as compared to non-polar (*n*-hexane, ethyl acetate) and polar (water) solvents.

NEWS

CIPROFLOXACIN - ALLY OR ENEMY?

Aortic dissection is the most common fatal disease process of the aorta and is precede in most cases by the aneurysm formation. Ciprofloxacin is one of the most often used antibiotic and it is prescribed to treat a broad spectrum of bacterial infections, including infected aortic aneurysm. Results of recent clinical studies revealed that treatment with fluoroquinolone is associated with an increased risk of acute aortic events. In a recent study, LeMaire *et al*., have induced a sporadic aneurysm formation in mice with high-fat diet and low-dose angiotensin infusion, the effects of ciprofloxacin on smooth muscle cells and frequency of acute aortic events were studied. The results were stunning, incidence of aortic dissection and rupture was almost 10 times higher in the group with ciprofloxacin and this outcome was linked to the increased level and activity of matrix metalloproteinase. Thus, this drug should be used with caution in patients with aortic dilatation and those at high risk for acute aortic events (Scott A. LeMaire, Lin Zhang, Wei Luo, *et al*. Effect of Ciprofloxacin on Susceptibility to Aortic Dissection and Rupture in Mice. *JAMA Surg*. doi:10.1001/ jamasurg. 2018.1804).

EVALUARE COMPARATIVĂ A COSTURILOR TEHNICII CHIRURGICALE LAPAROSCOPICE ÎN SISTEMELE DE SĂNĂTATE PUBLIC ŞI PRIVAT

B. Păltineanu[1], Vladimir Bacârea[2]
1. Institutul Naţional de Geriatrie şi Gerontologie "Ana Aslan"
Universitatea de Medicină şi Farmacie Târgu Mureş
2. Departamentul de Management Sanitar Academic şi Integrare Europeană

COMPARATIVE EVALUATION OF SURGICAL LAPAROSCOPIC TEHNIQUES COSTS IN PUBLIC AND PRIVATE HEALTH SYSTEMS (Abstract): Due to the fact that in Romania there are two health systems, public and private, some questions have been raised regarding the efficiency of a certain system, taking into account the quality but also the costs of provided services. **Material and method**: The study compares the costs of laparoscopic surgical techniques, analysing the causes of the differences that were found, if that were some advantages offered by one of the system to another and if there is a possibility of complementarity perspective between those two medical assistance organisation methods. **Key words**: LAPAROSCOPIC SURGERY, PUBLIC HEALTH SYSTEM, PRIVATE HEALTH SYSTEM

O chestiune puţin analizată în literatura de specialitate este perspectiva actuală (2010) asupra cheltuielilor legate de managementul pacientului chirurgical din punct de vedere al calculelor de eficienţă economică. Aceste cheltuieli implică spitalizarea efectivă, tehnica operaturie, medicaţia aferentă fiecărui pacient chirurgical la care s-a intervenit operator. Obiectivul principal este de a evidenţia, dacă există, diferenţele de costuri între abordarea endoscopică în spital de stat şi privat.

Scopul studiului este de a evalua sistemul public şi sistemul privat de sănătate prin prisma cheltuielilor de tratament (spitalizare, tehnică operatorie, medicaţie) în ceea ce priveşte tehnica chirurgicală laparoscopică.

Obiectivul principal este de a calcula diferenţele de costuri între abordarea endoscopică în spital de stat şi privat.

Obiective secundare:

- Stabilirea criteriilor de comparabilitate între cele două tipuri de intervenţie
- Descrierea intervenţiilor chirurgicale evaluate
- Stabilirea parametrilor de comparat în termeni de costuri şi eficienţă economică
- Compararea costurilor public vs privat

MATERIAL ŞI METODĂ

În prezentul studiu s-a ţinut cont de următoarele criterii de comparabilitate:

- Vârsta. Toţi pacienţii incluşi în studiu au avut vârsta mai mare de 18 ani.
- Sexul. Au fost incluşi pacienţi de ambele sexe.
- Tip afecţiune. Au fost selectaţi pacienţii cu aceeaşi afecţiune de bază fără diagnostice asociate sau complicaţii şi doar pacienţii internaţi şi operaţi în regim de programare.

1. Stabilirea parametrilor de comparat în termeni de costuri şi eficienţă economică

Pentru compararea costurilor privind pacientul chirurgical s-au luat în considerare următorii parametri:

- Medicaţia administrată pe parcursul internării
- Investigaţiile efectuate
- Numărul zilelor de spitalizare
- Materialele sanitare utilizate
- Manopera chirurgicală efectuată (endoscopică sau clasică)

Aceşti parametri au fost luaţi în considerare la compararea costurilor intervenţiilor endoscopice în sistem public vs privat.

Din punct de vedere al medicaţiei, atât în sistem public, cât şi în sistem privat s-au administrat aceleaşi clase de medicamente. Deasemenea s-au efectuat aceleaşi investigaţii de laborator, seturi de analize, ţinând cont de afecţiunea de bază.

În cazul zilelor de spitalizare, costul a fost raportat pe zi de spitalizare.

În ceea ce priveşte costul materialelor sanitare, la calcularea acestuia s-au luat în calcul toate materialele sanitare necesare pentru fiecare tip de intervenţie (colecistectomie laparoscopică, tratamentul herniei hiatale prin tehnica laparoscopică şi ovarectomia laparoscopică).

Manopera chirurgicală a fost calculată în funcţie de durata intervenţiei şi de numărul personalului medical din echipa operatorie.

Culegerea datelor a fost de tip exhaustiv.

2.Tehnica de eşantionare

S-a folosit eşantionul simplu randomizat.

Culegerea datelor de tip eşantion reprezentativ permite inferenţa statistică spre populaţia generală.

3.Evaluare statistică

Am aplicat pentru studiul statistic al datelor statistica descriptivă şi statistica inferenţială.

Statistica descriptivă. Prezentarea descriptivă a datelor se face prin înregistrarea datelor culese în tabele care să reprezinte în mod sintetic valorile măsurate.

Statistica descriptivă permite :

- Aprecierea prezenţei erorilor sau confuziei
- Reprezentarea datelor în tabele permite evaluarea fiecărui pacient şi dacă au existat pierderi din studiu
- Reprezentarea grafică a datelor pentru evaluarea mai eficientă a datelor culese despre pacienţii înrolaţi

S-au calculat indicatori statistici pentru descrierea repartiţiilor cazurilor luate în studiu pe grupe distincte, care studiate ne-au permis statuarea de concluzii pertinente relativ la scopul tezei. Pe baza datelor statistice astfel calculate am emis ipotezele inferenţei statistice cu ajutorul căreia am studiat diferenţele de care am avut nevoie în atingerea obiectivului studiului.

Statistica inferenţială. Variabilele folosite sunt continue. Diferenţierea variabilelor din punctul de vedere a distribuţiei se face folosind testul de normalitate Kolmogorov – Smirnov.

Pentru evaluarea lotului, precum şi pentru comparare de medii s-a utilizat testul t pentru un singur eşantion cu prag de semnificaţie $\alpha = 0,05$.

Pentru fiecare test statistic s-au verificat condiţiile de aplicare ale acestuia.

Interpretarea rezultatelor statistice a inclus evaluarea valorii p returnată prin aplicarea testului de inferenţă. Practic această valoare arată semnificaţia asocierii / semnificaţiei / diferenţei dintre variabilele studiate, scoţând în evidenţă diferenţa statistică prin compararea valorii p cu valoarea lui α. Am statuat din punct de vedere statistic următoarele : dacă $p > \alpha$ ($p > 0,05$) nu există semnificaţie statistică, dacă $p < \alpha$ ($p < 0,05$) există semnificaţie statistică.

Pornind de la premisa că semnificaţia statistică nu impune cu necesitate semnificaţia ştiinţifică şi viceversa am discutat rezultatele la limită $p \Leftrightarrow \alpha$ în funcţie de experienţa ştiinţifică a autorului.

Toate analizele statistice au fost realizate cu ajutorul programului Graphpad Prism 5.0 Trial pentru Windows.

TABELUL I
Colecistectomia laparoscopică

Colecistectomie laparoscopică	Sistem public	Sistem privat	Valoare p
Medicaţie	67,55	50,00	p > 0,05
Investigaţii	46,59	124,00	p < 0,05
Zi spitalizare	126,6	350,0	p < 0,05
Materiale sanitare	279,8	274	p > 0,05
Manoperă	90	950	-
Cost total	1149	2448	p < 0,05

* datele prezentate sunt superpozabile celor publicate in literatura de specialitate

REZULTATE

În prezentul studiu am evaluat abordarea laparoscopică din punct de vedere economico-financiar în sistemul public şi privat. Pentru fiecare tip de intervenţie s-au evaluat costurile medicaţiei, investigaţiilor de laborator, materialelor sanitare, costul raportat la o zi de spitalizare şi costul manoperei.

În cazul colecistectomiilor laparoscopice nu s-a observat o diferenţă semnificativă statistic în ceea ce priveşte costul medicaţiei. În sistem public, costul mediu al medicaţiei a fost de 67,55 ± 30,67 RON, faţă de 50 RON în sistemul privat. Costul mai scăzut în sistemul privat poate fi explicat prin evitarea poligragmaziei întâlnită des în sistemul public şi prin politica de preţuri diferită, adoptată atât de distribuitorii de medicamente, cât şi de furnizorul de servicii medicale private. O diferenţă semnificativă statistic s-a observat în cazul costurilor investigaţiilor de laborator pentru colecistectomia laparoscopică în sistemul privat faţă de cel public. Costul mediu al investigaţiilor de laborator în sistemul public a fost de 46,59 ± 40,77 RON faţă de 124 RON în sistemul privat. Această diferenţă de cost poate fi explicată prin modalitatea de amortizare a aparaturii de laborator adoptată de sistemul privat cât şi de eventualul „exces" în investigare, în argumentaţia unei eventuale complicaţii postoperatorii (tab. I).

Din punct de vedere al costului raportat la o zi de spitalizare, costul a fost mai crescut în sistemul privat, observându-se o diferenţă semnificativă din punct de vedere statistic. Costul mediu pentru o zi de spitalizare a fost de 350 RON în sistemul privat şi un cost mediu de 126,6 ± 49,31 RON pentru cel public. Un cost mai crescut în sistemul privat poate fi explicat de gradul sporit de confort oferit şi prin nivelul de salarizare al personalului implicat mai aproape de valoarea reală.

În cazul materialelor sanitare necesare, costul a inclus amortizarea echipamentelor şi a instrumentarului utilizat. S-a observat un cost mai ridicat în sistemul public, dar diferenţa nefiind semnificativă din punct de vedere statistic. Media costului materialelor sanitare necesare pentru sistemul public a fost de 279,8 ± 14,99 RON şi de 274 RON pentru sistemul privat.

Costul manoperei a fost evaluat în funcţie de durata tipului de intervenţie chirurgicală efectuată (laparoscopică sau clasică) şi de componenţa echipei operatorii.

În studiul de faţă în evaluarea costului manoperei s-a luat în considerare că echipa operatorie este formată din trei medici chirurgi şi o asistentă, un medic şi o asistentă ATI, iar durata unei intervenţii a fost considerată în medie de 36 minute pentru colecistectomia laparoscopică.

Costului manoperei pentru colecistectomia laparoscopică în sistem public a fost de 90 RON şi de 950 RON în sistem public. Costul mai ridicat în sistem privat poate fi

TABELUL II
Hernia hiatală

Cura laparoscopică a herniei hiatale	Sistem public	Sistem privat	Valoare p
Medicaţie	339	418	p > 0,05
Investigaţii	155,9	113	p < 0,05
Zi spitalizare	174,8	350	p < 0,05
Materiale sanitare	293,2	286	p > 0,05
Manoperă	120	2100	-
Cost total	2689	3967	p < 0,05

explicat prin posibilitatea oferirii de către angajatorul privat a unei remunerări a echipei medicale mai aproape de realitate.

În cazul colecistectomiei s-a observat o diferenţă semnificativă din punct de vedere statistic între costul total din sistemul public faţă de sistemul privat, costul total mediu fiind de 1149 ± 321,7 RON în sistemul public şi de 2448 RON în cel privat.

În cazul herniilor hiatale s-a observat o diferenţă nesemnificativă statistic în ceea ce priveşte costul medicaţiei. În sistemul public, costul mediu al medicaţiei a fost de 339 ± 67,26 RON, faţă de 418 RON în sistemul privat. Costul ridicat poate fi explicat prin medicaţia mai modernă şi mai „safe" utilizată (tab. II).

S-a observat o diferenţă semnificativă statistic în cazul costurilor investigaţiilor de laborator pentru hernia hiatală în sistem public faţă de cel privat. Costul mediu al investigaţiilor de laborator în sistem public a fost de 155,9 ± 25,09 RON şi 113 RON pentru sistemul privat. Această diferenţă de cost poate fi explicată prin investigaţiilor mai amănunţite în vederea unui stabilirii unui diagnostic pozitiv şi efectuării unuia diferenţial, cât şi examenului asociat cât mai minuţios în scopul evitării unor „surprize" neplăcute atât pre, per, intra şi postoperatorii.

Din punct de vedere al costului raportat la o zi de spitalizare, costul a fost mai crescut în cazul sistemului privat, obţinându-se o diferenţă semnificativă din punct de vedere statistic. Costul mediu pentru o zi de spitalizare a fost de 174,8 ± 13,38 RON pentru sistemul public şi un cost mediu de 350 RON pentru sistemul privat. Un cost mai crescut în sistemul privat poate fi explicat gradul de confort sporit şi de nivelul de salarizare mai aproape de realitate al personalului medical.

În cazul materialelor sanitare necesare, costul a inclus amortizarea echipamentelor şi a instrumentarului utilizat. S-a observat un cost mai ridicat în cazul sistemului public, diferenţa fiind nesemnificativă din punct de vedere statistic. Media costului materialelor sanitare necesare pentru hernia hiatală în sistemul public a fost de 293,2 ± 27,34 RON şi de 286 RON în cel privat.

Costul manoperei a fost evaluat în funcţie de durata tipului de intervenţie chirurgicală efectuată (laparoscopică sau clasică) şi de componenţa echipei operatorii.

În studiul de faţă în evaluarea costului manoperei s-a luat în considerare că echipa operatorie este formată din trei medici chirurgi şi o asistentă, un medic şi o asistentă ATI, iar durata unei intervenţii a fost considerată în medie de 48 minute pentru hernia hiatală prin tehnica laparoscopică.

Valoarea medie a costului manoperei pentru hernia hiatală prin în sistem public a fost de 120 RON şi de 2100 RON pentru sistemul privat. Costul mai ridicat în sistem privat poate fi explicat

În cazul herniilor hiatale s-a observat o diferenţă semnificativă din punct de vedere statistic între costul total în sistem public faţă de cel privat, costul total mediu pentru public fiind de 2689 ± 1 RON şi de 3967 RON pentru sistemul privat.

TABELUL III
Ovarectomia laparoscopică

Ovarectomie laparoscopică	Sistem public	Sistem privat	Valoare p
Medicaţie	101,7	235	p > 0,05
Investigaţii	75,25	50	p < 0,05
Zi spitalizare	157,2	350	p < 0,05
Materiale sanitare	302,6	123	p > 0,05
Manoperă	90	2200	-
Cost total	1577	3621	p < 0,05

În cazul ovarectomiilor s-a observat o diferenţă semnificativă statistic în ceea ce priveşte costul medicaţiei. În sistem public, costul mediu al medicaţiei a fost de 101,7 ± 8,86 RON, faţă de 235 RON. Costul ridicat poate fi explicat prin medicaţia mai modernă şi mai „safe" utilizată (tab. III).

În ceea ce priveşte costul investigaţiilor de laborator s-a observat o diferenţă semnificativă statistic pentru sistemul public faţă de cel privat. Costul mediu al investigaţiilor de laborator pentru sistemul public a fost de 75,25 ± 6,43 RON şi 50 RON pentru sistemul privat.

Din punct de vedere al costului raportat la o zi de spitalizare, costul a fost mai crescut pentru sistemul privat, observându-se o diferenţă semnificativă din punct de vedere statistic. Costul mediu pentru o zi de spitalizare a fost de 157,2 ± 2,47 RON pentru sistemul public şi un cost mediu de 350 RON pentru sistemul privat. Un cost mai crescut în sistemul privat se explică atât prin gradul sporit de confort oferit, cât şi prin nivelul de salarizare mai aproape de salarizarea reală a personalului medical.

În cazul materialelor sanitare necesare, costul a inclus amortizarea echipamentelor şi a instrumentarului utilizat. S-a observat un cost mai ridicat în sistemului public, diferenţa fiind semnificativă din punct de vedere statistic. Media costului materialelor sanitare necesare pentru ovarectomia laparoscopică în sistem public a fost de 302,6 ± 13,39 RON şi de 123 RON în sistem privat.

În evaluarea costului manoperei s-a luat în considerare că echipa operatorie este formată din trei medici chirurgi şi o asistentă, un medic şi o asistentă ATI, iar durata unei intervenţii a fost considerată în medie de 36 min pentru colecistectomia laparoscopică.

Valoarea medie a costului manoperei pentru ovarectomia laparoscopică în sistem public a fost de 90 RON şi de 2200 RON pentru sistemul privat. Costul mai ridicat în sistem privat poate fi explicat prin posibilitatea negocierii unui contract mai mare de către chirurg la angajare.

În cazul ovarectomiei s-a observat o diferenţă semnificativă din punct de vedere statistic între costul total în sistem public faţă de cel privat, costul total mediu în sistem public fiind de 1577 ± 2,07 RON şi de 3621 RON în sistem privat.

DISCUŢII

În prezentul studiu, s-a observat un cost crescut al medicaţiei în sistemul public în comparaţie cu sistemul privat privind colecistectomia laparoscopică, dar diferenţa nefiind una semnificativă, costul mai scăzut în sistemul privat poate fi explicat prin evitarea poligragmaziei întâlnită adesea în sistemul public şi prin politica de preţuri diferită, adoptată atât de distribuitorii de medicamente, cât şi de furnizorul de servicii medicale private. În cazul celorlalte intervenţii, hernia hiatală prin tehnica laparoscopică, deşi s-a observat un cost crescut al medicaţiei în sistemul privat în comparaţie cu

sistemul public, nu s-a putut arăta o diferenţă semnificativă. În ceea ce priveşte costul medicaţiei pentru ovarectomia laparoscopică, s-a observat un cost mai ridicat în sistemul privat faţă de sistemul public, diferenţa fiind una semnificativă.

Din punct de vedere al costului investigaţiilor de laborator, acesta a fost mai crescut în sistemul privat în cazul colecistectomiilor laparoscopice, diferenţa fiind semnificativă, şi mai crescut în sistem public în cazul herniei hiatale şi ovarectomiilor prin tehnica laparoscopică, diferenţa fiind deasemenea semnificativă. Toate acestea se datoresc atât investigaţiilor mai amănunţite în vederea unui stabilirii unui diagnostic pozitiv şi efectuării unuia diferenţial, cât şi examenului asociat cât mai minuţios în scopul evitării unor „surprize" neplăcute atât pre, per, intra şi posoperatorii.

În ceea ce priveşte costul raportat pe zi de spitalizare, acesta a fost mai ridicat în sistem privat pentru toate intervenţiile studiate, diferenţa fiind una semnificativă faţă de sistemul public.

În cazul materialelor sanitare necesare, costul a fost evaluat pentru fiecare intervenţie (colecistectomie, tratamentul herniei hiatale şi ovarectomii prin tehnică laparoscopică). S-a observat un cost mai ridicat în sistemul public, diferenţa nefiind una semnificativă în cazul colecistectomiilor şi tratamentului herniei hiatale şi semnificativă în cazul ovarectomiilor.

Costul manoperei a fost evaluat în funcţie de durata tipului de intervenţie chirurgicală efectuată şi componenţa echipei operatorii. S-a observat un cost mai crescut în sistemul privat faţă de cel public, diferenţa fiind una semnificativă, având în vedere calificarea, expertiza şi corolar nivelul de salarizare al echipei medicale atrase în sectorul privat.

CONCLUZII

Evaluând costul total al intervenţiilor laparoscopice studiate s-a observat un cost crescut în sistemul privat faţă de cel public, diferenţa fiind semnificativă în sensul componentelor costului mai sus-amintite.

SERUM LIPOPROTEIN(A) LEVELS IN PATIENTS WITH ARTERIAL HYPERTENSION (Abstract): Lp(a) is capable of deleteriously altering the balance between the procoagulant and anticoagulant, proinflammatory and anti-inflammatory, and vasorelaxing and vasoconstricting properties of the endothelium. **Material and method**: The purpose of this study was to investigate the serum concentration of Lp(a) and the main parameters of lipid profile in three groups of subjects: a control group that included 16 healthy subjects, 20 patients with arterial hypertension and dyslipidemia and 20 patients with arterial hypertension without dyslipidemia. Using B-mode ultrasonography, we evaluated carotid intima-media thickness (IMT) and flow mediated vasodilation (FMD) on brachial artery. **Results**: We found significant higher Lp(a) concentrations in hypertensive patients with dislipidemia (70 ± 55.95 mg/dL, $p < 0.001$) and in hypertensive patients without dislipidemia (69 ± 52.33 mg/dL, $p < 0.001$), comparative with the control group (19 ± 14.64 mg/dL). In hypertensive patients with dislipidemia we found a strong negative correlation between Lp(a) and carotid IMT ($R^2 = -0.75$, $p < 0.001$) and a moderate negative correlation between Lp(a) and FMD ($R^2 = -0.38$, $p < 0.001$). Lp(a) level wasn't correlated with the main parameters of lipid profile. **Conclusions**: These results indicated that serum Lp(a) values could play an important role in essential hypertension pathogenesis and could be considered as an individual risk factor in hypertensive patients. **Key words**: HYPERTENSION, SERUM LIPOPROTEIN(A), INTIMA-MEDIA THICKNESS, FLOW–MEDIATED VASODILATION

Lipoprotein(a) [Lp(a)] is a unique, complex macromolecule consisting of a particle of low density lipoprotein (apo B100) linked to apolipoprotein(a), a molecule that is highly homologous with plasminogen (1). Elevated Lp(a) levels might promote cardiovascular events not by inducing or enhancing atherosclerosis, by stimulation of smooth muscle cell migration and proliferation (2) or by inducing endothelial chemoatractant activity (3), but mainly by its prothrombotic properties. Additionally, Lp(a) has been associated with high blood pressure (4), diabetes mellitus (5, 6) and dyslipidemia (7).

In hypertensive patients, a modification of the lipid profile has been observed, with increased levels of total cholesterol, triglycerides and LDL-C and low blood concentrations of HDL-C (8).

Carotid artery intima-media thickness (IMT), measured noninvasively by high-resolution B-mode ultrasonography, has been

associated with the risk of coronary artery disease, stroke, and myocardial infarction, and it predicts the progression of coronary artery disease (9). A positive associations between Lp(a) and IMT, a well-established surrogate index of coronary atherosclerosis, was reported in some studies (10, 11).

Ultrasonographical measurement of flow-mediated dilation (FMD) of the brachial artery allows direct and noninvasive assessment of endothelial-dependent vascular function. An impairment of FMD has been demonstrated in subjects with uncomplicated hypertension (12).

Because endothelial dysfunction occurs at a preclinical stage of disease, its presence serves as a highly sensitive disease marker that may help clarify the pathogenic role of Lp(a) in hypertensive patients.

The present study was conducted in order to measure Lp(a) levels, the main parameters of lipid profile, IMT and FMD values in hypertensive patients with or without dyslipidemia, with no clinical signs of associated pathologies or organ damage.

MATERIAL AND METHOD

In a 24 months period, fifty-six subjects from the IVth Medical Clinic of the University of Medicine and Pharmacy Victor Babes Timişoara were included in the study that comprised 20 patients with arterial hypertension and dyslipidemia (45% males, 55% females), 20 patients with arterial hypertension without dyslipidemia (25% males, 75% females), and 16 healthy subjects (31% males, 69% females), aged between 50-60 years old and sex ratio 45 men (66%) and 23 women (34%).

Venous blood samples were withdrawn in the morning, after an overnight fast. Serum total cholesterol triglycerides, high density lipoprotein – cholesterol (HDL – C) and fasting glucose concentrations were determined in all patients (Abbott photometry). The low density lipoprotein – cholesterol (LDL – C) concentration was calculated using Friedewalds' equation (13). Lp(a) was measured by a commercially available sandwich ELISA (Mercodia AB, Uppsala, Sweden).

Clinic blood pressure was recorded following the recommendations of the 2007 European Society of Hypertension/European Society of Cardiology guidelines (14). Dyslipidemia was based on the current European Society of Cardiology guidelines on cardiovascular disease prevention in clinical practice (15).

Assessment of vascular function

IMT was measured by high-resolution B-mode ultrasonography with an ultrasonographical apparatus with linear transducer of 7.5 MHz (Model ProSound SSD-4000, Aloka Co., Ltd., Tokyo, Japan), in both carotid arteries, on the distal straight 1 cm of the common carotid arteries, the carotid bifurcations, and the proximal 1 cm of the internal carotid arteries. The carotid IMT was determined as the average of 12 measurements (both sides 6 measurements each from the near and far wall of each of the three segments). A value >0.9 mm was considered abnormal.

Endothelial function was assessed by means of FMD on the brachial artery. Smooth muscle dilation was tested by 400 μg of sublingual nitroglycerin followed by imaging at 3 min after oral absorption (NTG).

The procedures followed were in accordance with the ethical standards of the Hospital Ethics Committee and with the Helsinki Declaration of 1975, as revised in 2000.

Data analysis

Continuous variables were expressed as means $\pm$ SD. Means were compared using analysis of variance or the Student t-test. The correlations between Lp(a) and all the remaining parameters studied were checked using the Spearman correlation test, taking Lp(a) as an independent variable. Statistical significance was defined as two–sided $p < 0.05$. All statistical analyses were performed using Excel Microsoft Office 2003.

RESULTS

The baseline characteristics of the subjects from the three groups are summarized in table I. The three groups were similar in terms of age, sex, family history of cardiovascular disease, smoking habits, and body mass index. The average of systolic and diastolic blood pressure values was higher in hypertensive patients, with or without dislipidemia, comparative with control group.

Table II describes serum lipid and lipoprotein profiles of the patients in the study groups. The plasma concentration of total cholesterol, triglycerides, LDL-cholesterol and non HDL-cholesterol were higher in hypertensive group with or without dislipidemia than in the controls ($p < 0.001$).

The most elevated concentrations of Lp(a) were found in hypertensive group with dislipidemia (70 ± 55.95 mg/dL, $p < 0.001$) comparative with hypertensive group without dislipidemia (69 ± 52.33 mg/dL, $p < 0.001$), and with the control group (19 ±

14.64 mg/dL).

In table III are described the correlations between Lp(a) levels and other parameters in hypertensive group with dislipidemia. The Lp(a) levels wasn't correlated with the main parameters of lipid profile.

In hypertensive group with dislipidemia we found a strong positive correlation between Lp(a) and carotid IMT ($R^2 = 0.75$, $p < 0.001$) (fig. 1), and a moderate negative correlation between Lp(a) and FMD ($R^2 = -0.38$, $p < 0.001$) (fig. 2).

DISCUSSIONS

In our study that included patients with essential arterial hypertension with or without dislipidemia, with no clinical signs of pathologies or organ damage and with no family histories of cardiovascular disease, we measured the plasma concentration of Lp(a), the main parameters of lipid profiles and we assessed ultrasonographically the IMT and FMD values. Our results indicated that patients with arterial hypertension with or without dislipidemia have increased levels of Lp(a). Elevated concentrations of Lp(a) in hypertensive patients could constitute a first pathological sign, in the absence of noticeable organ damages and could be considered a negative factor of prognosis. Some authors indicated a positive correlation between high Lp(a) concentration and a positive family history of cardiovascular disease in hypertensive patients (16).

In vitro experiments have also illustrated that oxidized Lp(a) is able to impair the arterial endothelium-dependent dilation, and suggested a possible role of Lp(a) in the genesis of essential hypertension (17, 18). The relationship between Lp(a) and FMD was evident in our study, the subjects with increased levels of Lp(a) presented a markedly reduced FMD.

Previously, several studies have found Lp(a) to be related to early structural changes of the carotid arteries as measured by IMT (19). The localization of Lp(a) within the arterial wall suggests a direct causative role for Lp(a) in the initiation or progression of atherosclerosis. In our study, in the group of patients with arterial hypertension and dislipidemia, subjects with elevated levels of Lp(a) presented increased values of IMT.

Understanding of the relationship between Lp(a) and other cardiovascular disease risk factors through larger studies will be useful in understanding the mechanism by which Lp(a) participates in the atherosclerotic process (20).

CONCLUSIONS

We can say that hypertension and dislipidemia, which are two of the main risk factors for vascular disease, are often associated. Elevated Lp(a) values seems to be an important independent coronary risk factor that aggravates the coronary risk exerted by elevated LDL cholesterol, low HDL cholesterol, hypertension or the combined effects of multiple risk factors. Lp(a) should play a role as a screening tool in the quotidian clinical practice.

THE EFFECTS OF SOME NONPOLAR AMINOACIDS – VALINE, LEUCINE – ADMINISTRATION ON THE ARTERIAL WALL ALREADY EXPOSED TO A HYPERCHOLESTEROLEMIC DIET(Abstract) : Hypercholesterolemia plays an important role in atherosclerosis. The dietary supplementation of proteins or specific aminoacids seems to enhance the immune status in animals and humans with a complex pathological status, decreasing morbidity and mortality. **Aim** : In the present study we intended to analyse the effects of some nonpolar aminoacids- valine and leucine on cholesterol blood levels in a high-fat-diet in rats. In the same time we evaluated the vascular walls impact produced by the hypercholesterolemic diet. **Material and methods** : Our experiment was realised on 32 male Wistar rats, which were fed with cholesterol, valine and leucine for 8 weeks. At the end of experiment we analysed serum levels of cholesterol and also histopathological features of hypercholesterolemia on the arterial wall. **Conclusion** : The results of our study indicate that valine and leucine decrease the serum cholesterol and therefore the hypercholesterolemic-induced prooxidant status of the body being useful in reducing atherosclerosis. **Key words** : VALINE, LEUCINE, PLASMA CHOLESTEROL, HYPERCHOLESTEROLEMIA, ATHEROSCLEROTIC LESIONS

VEMURAFENIB BASED HYDROGELS AS POTENTIAL TOPICAL BIOFORMULATIONS FOR THE TREATMENT OF MELANOMA

VEMURAFENIB BASED HYDROGELS AS POTENTIAL TOPICAL BIOFORMULATIONS FOR THE TREATMENT OF MELANOMA (Abstract): One of the most aggressive forms of cancer, cutaneous melanoma, occurs as a result of uncontrolled division of melanocytes. The efficacy of the used treatments can be diminished in terms of targeted action, increased toxicity and resistance to treatment. In the present study we have investigated an antitumor agent from the BRAFV600 inhibitor class, namely vemurafenib, currently approved by the FDA and EMA for oral administration only. Due to its high toxicity, we evaluated the possibility of cutaneous administration for the treatment of early-stage melanoma or post-surgical resection. **Materials and methods**: In that regard, we considered hydrogels based on chitosan, β-cyclodextrin and polyvinyl alcohol in various concentration ratios from which, after a careful analysis of the previously published data, we chose two matrices to be loaded with vemurafenib. **Results:** The inclusion complexes were obtained by PVA gelation through repeated freeze-thaw cycles and subsequently characterized by FTIR, scanning electron microscopy and swelling capacity at various pH and temperature values. **Conclusions**: The obtained results were promising, as the synthesized formulations proved their capability of controlled release for vemurafenib. **Keywords:** CHITOSAN, β-CYCLODEXTRIN, POLYVINYL ALCOHOL, HYDROGEL, VEMURAFENIB, SMART DRUG DELIVERY.

INTRODUCTION

In view of the increasing number of malignant pathologies being diagnosed, the medical world is showing a keen interest in the study of new systems for the transportation and targeted delivery of active substances with selectivity towards cancer cells, minimal toxicity to healthy tissue and fewer side effects. In that regard, numerous transport systems have been synthesized, including smart hydrogels that have gained notoriety in recent years in medical research. Invasive melanoma accounts for 1% of all skin cancer cases with very poor

prognosis, being the least common but the deadliest type of skin cancer in the incidence of which, the main involved factors are UV irradiation, prolonged sun exposure, light skin tone, family history of melanoma, higher numbers of melanocytic nevi and chronic immunosuppression. Death occurs as a result of metastasis, a stage characterized by increased tumor cell invasion and migration of cancer to other organs. The main method of treatment is surgical resection with excellent long-term prognosis, but in advanced melanoma (stage III-IVB), that approach is not sufficient and must be complemented by other therapeutic methods considering the spread of cancer cells to several organs (1, 2). Although surgical resection remains a gold standard for the treatment of melanoma, certain cases in which that approach is not possible, such as those in which patients are not suitable surgery-candidates depending on tumor/patient's characteristics, must also be considered as a second-line therapy. In that context, two possible options are the topical application of a specific drug or the radiation therapy, being the only ones that have proven a certain therapeutic efficacy. Other therapeutic approaches such as liquid nitrogen cryotherapy, electrodesiccation, curettage, laser surgery, and fluorouracil 5% cream have been linked with a high risk of recurrence and are not recommended. Currently, the only cream available on the pharmaceutical market but used off-label for the treatment of melanoma is imiquimod 5%, as adjuvant therapy (3).

Targeted therapy of cutaneous melanoma has developed based on the observation that more than 66% of malignant cases presented somatic missense mutations of protein kinase b-raf (BRAF). 69 BRAF mutations result in high serine/threonine kinase activity and mediate cell proliferation through the regulation of the mitogen-activated protein kinase (MAPK) signaling pathway. The most widespread variant is a val-to-glu point mutation at codon 600 (V600 E), which benefits from the treatment with VEM, which has been designated an orphan drug by the FDA for the treatment of BRAF V600E mutation-positive stage IIB to IV melanoma and it is not indicated for use in patients with wild-type BRAF. When evaluating physico-chemical properties of numerous antitumor drugs, specifically their solubility, we observed that most of them had low solubility in water, raising bioavailability issues (6). Attempts on the topical application of VEM have also been made in other studies, e.g., in the form of a solid-in-oil nanodispersion as an efficient and safe way to deliver VEM in early-stage melanoma (7). Peuvrel *et al.* (8) reported the appearance of skin rashes as a toxic response to a prolonged dermal treatment with VEM. That problem could be solved through formulation related strategies. One of them could be the inclusion of the drug within a biopolymeric matrix which can improve targeted drug delivery and diminish its cutaneous toxicity. This could not only target better VEM to the site but also to buffer its skin toxicity.

Analyzing the option of topical application, we have considered the synthesis of a chitosan (CS)-based hydrogel combined with β-cyclodextrin (β-CD) to allow controlled and targeted release of VEM and to counteract its limitations imposed by low water solubility and by its toxicity.

Due to its structural properties, in particular the presence of amino groups on the polysaccharide chain, CS is a biopolymer that exhibits certain properties that make it

suitable for biomedical applications such as high biocompatibility, low immunogenicity and allergenicity. CS is obtained by the deacetylation of chitin and it is a polysaccharide biomaterial composed of β-(1-4)-2-acetamido2-deoxy-β-D-glucopyranose and 2-amino-2-deoxy-β-D-glucopyranose. The combination of CS with β-CD can provide unique benefits, particularly when administering hydrophobic medications. Cyclodextrins are produced by *Bacillus macerans* and from a chemical point of view they are a particular category of oligosaccharides obtained from the enzymatic degradation of starch. β-CD is a derived oligosaccharide with electron-rich glycosidic oxygen atoms, that has a hydrophobic central cavity that can integrate hydrophobic molecules such as VEM in the presence of water and thus forming inclusion complexes with various drugs and bioactive molecules. Moreover, its ability to improve the solubility of certain drugs and the permeability of some macromolecular substances have also been demonstrated (9).

As Wang *et al.* (10) demonstrated in their study, the copolymer chitosan-grafted β-cyclodextrin (CS-g-β-CD) showed an improved hydrophilicity as its porous structure is advantageous for the complete exposure of polar functional groups (amino and hydroxyl groups) on its surface, being a smart drug carrier for etoposide, another anticancer drug.

The present study aimed to develop a method that combined CS and β-CD as hydrogels within an optimal composition to include VEM as the active substance. The obtained formulation was intended for topical delivery of VEM, the matrix being analyzed as a potential alternative to the topical preparations that are currently used. The preparation of the CS/β-CD complex is based on CS's ability to act as a cationic polymer to generate hydrogels (11,12) and to modulate the complex's properties, such as controlled release of drugs (13) by varying the external stimuli (i.e., pH), leading to smart delivery systems. An additional crosslinking was necessary because of the requirement that the biopolymeric matrix must be resistant to enzyme activity and other physicochemical factors. A non-invasive crosslinking strategy is physical crosslinking with the help of polyvinyl alcohol (PVA) involving the hydrogen bonding process, leading to a strong gel without external crosslinking agents. That type of gelation may provide biocompatible hydrogels of very high purity, with enhanced mechanical strength, with recently discovered inherent self-healability, that are extremely useful for post-surgery applications (14-16). The present study had its premises in a previous work done by Cheaburu *et al.*, where the behavior of an antimycotic drug with unfavorable pharmaco-toxicological profile for oral and/or parenteral administration was studied by loading it into a similar CS-based hydrogel, namely a CS-g-PNIPAAm/PVA copolymer, intended for topical mucosal application, with promising results (17).

MATERIALS AND METHODS

Materials. In our experiment, we have used the following materials: vemurafenib (VEM), chitosan (CS, 75-80% degree of deacetylation), β-cyclodextrin (β-CD), polyvinyl alcohol (PVA, 99% hydrolyzed with Mw of 89,000-98,000 Da), and phosphate buffered saline tablets pH = 7.4 (PBS), all purchased from Sigma-Aldrich, St. Louis, MO, USA. Other materials not mentioned were of analytical grade and used without further purification. All aque-

ous solutions were prepared using ultrapure water (Milli-Q, Millipore).

Preparation of Freeze-Thaw Hydrogels CS/β-CD/PVA. For the preparation of the hydrogels, we synthesized chitosan and β-cyclodextrin complexes (CS/β-CD) by solution mixing of 2 wt.% solution of CS in 0.5% acetic acid solution and 2 wt.% solution of β-CD in various ratios to obtain complexes with various compositions. Freeze-thaw hydrogels were prepared by mixing the prepared solutions of CS/β-CD with 5 wt.% PVA solution. Gelation strategy involved the freeze-thaw technique conducted by exposing the product to freezing temperatures (approximately -20°C) for 20 hours, and then allowing it to thaw at room temperature (RT) for 4 hours. The process of freezing and thawing (F-T cycles) was repeated three times. The number of F-T cycles was determined considering the previously obtained results of texture profile and rheological analyses of the grafted chitosan crosslinked with PVA being suitable for topical application and requiring low hardness and good adhesion properties. Additionally, freeze-thaw hydrogels chitosan/PVA and β-CD/PVA were prepared as reference matrices with the same compositions. Table I details the list and the precise composition of each prepared hydrogel.

TABLE I.
List of synthetized hydrogels

CODE	FORMULATION
CS/β-CD/PVA 25/70/5 + VEM	Hydrogel CS/β-CD physically crosslinked with PVA (25/70/5 combination ratio); loading with VEM was done by solution mixing after hydrogel preparation
CS/β-CD/PVA 25/70/5	Hydrogel CS/β-CD physically crosslinked with PVA (25/70/5 combination ratio), without VEM
CS/β-CD/PVA 20/75/5 + VEM	Hydrogel CS/β-CD physically crosslinked with PVA (20/75/5 combination ratio); loading with VEM was done by solution mixing after the hydrogel preparation
CS/β-CD/PVA 20/75/5	Hydrogel CS/β-CD physically crosslinked with PVA (20/75/5 combination ratio), without VEM
CS/β-CD/PVA 45/50/5	Hydrogel CS/β-CD physically crosslinked with PVA (45/50/5 combination ratio), without VEM
CS/β-CD/PVA 5/90/5	Hydrogel CS/β-CD physically crosslinked with PVA (5/90/5 combination ratio), without VEM
β-CD/PVA 95/5	Hydrogel containing only β-CD with PVA (95/5 combination ratio)by three cycles of −20/25°C freeze-thaw, without VEM
where: CS/β-CD - chitosan and β-cyclodextrin complexes; PVA - polyvinyl alcohol; VEM - Vemurafenib.	

Preparation of Vemurafenib loaded hydrogels. The biopolymeric matrices' characteristics were analyzed by means of FT-IR spectroscopy and swelling tests. The most suitable hydrogels for VEM loading designated for topical application were determined to be CS/β-CD/PVA 25/70/5 and CS/β-CD/PVA 20/75/5.

The drug loading was done by dissolving 1.5 mg VEM in 100 μL of DMSO (due to low water solubility) and mixed with β-CD solution and then complexed with CS and crosslinked with PVA. The proposed reaction mechanism is illustrated in figure 1.

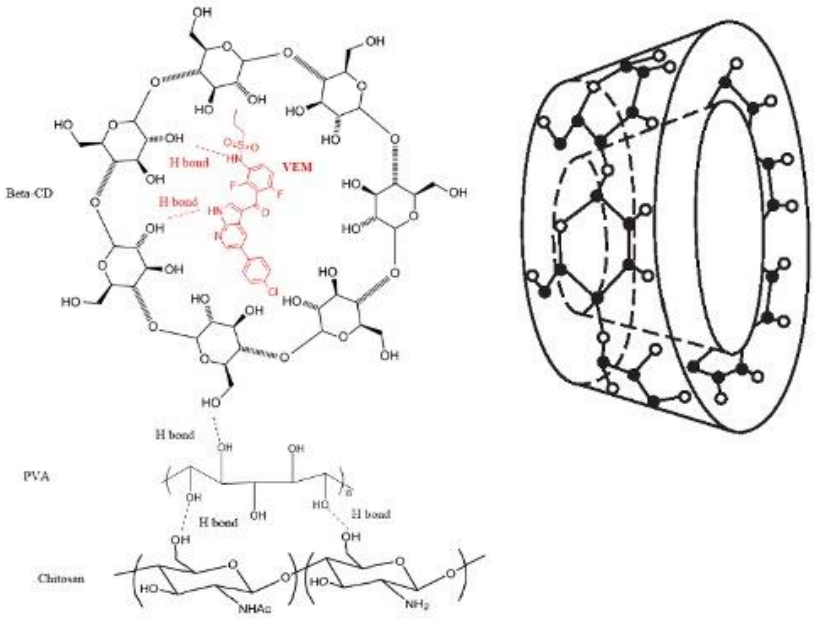

Fig. 1. Proposed preparation mechanism of biopolymeric based hydrogels

Characterization methods

The prepared complexes with various compositions in CS and β-CD with and without VEM and finally gelified by cross-linking with PVA were analyzed by means of structural identity, ability to swell on a substrate, morphological observations and drug loading capacity.

1. FTIR Spectroscopy

The chemical characterization of the obtained final hydrogels and individual components was accomplished by employing a Perkin Elmer Spectrum-100 instrument (Shelton, CT, USA), through reflection on a diamond crystal with a 45° angle, 4 cm^{-1} resolution of and over the 4000-400 cm^{-1} range

2. Hydrogel swelling behavior

The swelling behavior of the freeze-dried hydrogels was evaluated by direct immersion of formulations in acidic medium, water, and phosphate buffer saline (PBS, pH = 5.5) at various temperature values to simulate medium conditions for further *in vitro* experiments. The samples were periodically removed from the solution, wiped with a soft tissue to remove surface solution, weighed, and then carefully placed back into the beaker as quickly as possible.

The swelling degree (Q%) was calculated according to Equation (1):

$$Q\% = \frac{w_t - w_d}{w_d} \times 100 \quad (\mathbf{1})$$

where w_t is the weight of the swollen samples at time t and w_d is the weight of the dry sample.

3. Morphological observations characterization of the hydrogels

The scanning electron microscopic (SEM) images of cross-sections of the lyophilized hydrogels were captured using a Hitachi SU 1510 Scanning Electron Mi-

croscope (Hitachi Company, Japan), while the samples were set on an Aluminum stub and coated with a 7 nm thick gold layer using a Cressington 108 device before observation, at various magnification levels.

4. Drug loading capacity (DL) and drug entrapment efficiency (DEE%) of the formulations

The amount of VEM loaded in the hydrogels was determined by using a high-pressure liquid chromatography (HPLC) system Shimadzu Nexera LC-40-XR (Shimadzu, Kyoto, Japan) equipped with a serial dual-plunger pump, an autosampler (SIL 40 XR), a SPD-40V series UV-Vis, and a RF-20Axs fluorescence detector. The chromatographic separation of VEM was performed on a Waters CORTECS C18 column (2.1 × 100 mm, 2.7 μm) using as mobile phase a mixture of: A (water/formic acid - 99.9/0.1, *v/v*), B (acetonitrile) and C (methanol). Before use, the solvents were filtered through a 0.22 μm filter and degassed by ultrasonication. The injection sample volume was 10 μL, the run time was 9 min in isocratic mode (1 mL/min), and the optimal mobile phase ratio was A (40%), B (55%) and C (5%). The column temperature was maintained constant at 30°C during the chromatographic operation with UV-Vis detection for VEM (λ = 252 nm). The quantitative and qualitative analysis of VEM was based on its retention time and peak areas, respectively. The LabSolutionDB software 6.106SP1 was used for peak integration.

The calibration curve for VEM was obtained using the following procedure: stock solutions of VEM were prepared by dissolving 0.002 g of pure drug using acetonitrile in a 10 mL volumetric flask, from which we made serial dilutions, in the 100-0.78125 mg/L concentration range (r^2 = 0.9999). We found that VEM has a retention time of 6 min. To quantify the drug from the loaded matrices, we weighed the hydrogel samples, and after dissolution in 50/50 (*v/v %)* methanol/acetonitrile mixture using 2 mL vials, we centrifuged them, filtered the supernatants through 0.22 μm filter, and then 10 μL of each sample was injected and analyzed using the HPLC method described above. We also determined the limit of detection, LOD = 10.7982 μg/mL and the limit of quantification, LOQ = 32.7216 μg/mL. The amount of loaded VEM was calculated using Equation (2) derived from the calibration curve:

$$y = 45988x + 11405;\ r^2 = 0.9999 \quad \textbf{(2)}$$

The drug entrapment efficiency (DEE) represents the quantity of loaded drug (%) that is encapsulated in the formulation. The DEE of VEM from the hydrogel was calculated using Equation (3).

$$\textbf{DEE} = \frac{\text{Actual drug (VEM) content loaded in the matrix}}{\text{Theoretical drug content (VEM)}} \times 100 \quad \textbf{(3)}$$

RESULTS AND DISCUSSION

Given that the aim of the study was to optimize a treatment option for cutaneous melanoma for topical application and that semisolid forms are the most commonly used formulations for the transport of active substances through skin (18), we chose the option of incorporating an antitumor drug (VEM) in a hydrogel. The advantages are multiple, first of all the reduced risk of side effects, an enhanced patient compliance to treatment given the non-irritant properties of the hydrogels and their ability not to disrupt skin functions.

We selected the hydrogels' preparation method using PVA, a physical cross-linking agent with high biocompatibility and high mechanical strength, due to the simplicity of their synthesis process. We chose the typical preparation method by three freeze-thaw (F-T) cycles. As it is known, the number of cycles is correlated with their stability, so including a higher amount of PVA should be advantageous in the gelation process.

Structure Identification of Hydrogels

FTIR Spectra. The FTIR spectra of CS, β-CD, CS/β-CD/PVA and of the loaded hydrogels are presented in figure 2. We can observe in the graph the following representative aspects for β-CD: broad transmittance peak at 3303 cm^{-1} due to -OH stretching vibrations, asymmetric stretching vibrations of -CH were represented at 2928 cm^{-1} whereas asymmetric stretching vibrations of C-O were represented at 1633 cm^{-1}. A band at 1021 cm^{-1} was due to coupling vibrations of C-O and C-C. A characteristic band observed at 897 cm^{-1} was due to the vibration of α-(1-4) glucopyranose ring of β-CD, indicating the success of complexing β-CD to the polymeric backbone of CS. As far as the characteristic peaks of CS are concerned, from the graph we can deduce the following aspects: characteristic peaks at 2921-2887 cm^{-1} ($-CH_3$, $-CH_2$), 1636 cm^{-1} (C=O stretch vibration), 1548 cm^{-1} (secondary amide), 1655 cm^{-1} (amide band I) and 1068-1020 cm^{-1} (C-O stretching of saccharide moiety). The IR spectra of VEM should exhibit distinct absorption bands at 1734 cm^{-1} (C=O), 1325 and 1147 cm^{-1} (SO_2), and 1635 cm^{-1} (C=N), 817 cm^{-1} (C-Cl), not all very clearly observed because of the small amount that we have used for drug loading, but consistent with other studies (19). The intermolecular hydrogen bonding formed in between the drug and β-CD were evidenced by the widening of OH groups. Moreover, the hydrogel's formation is based also on hydrogen bonding, evidenced within the spectra as well.

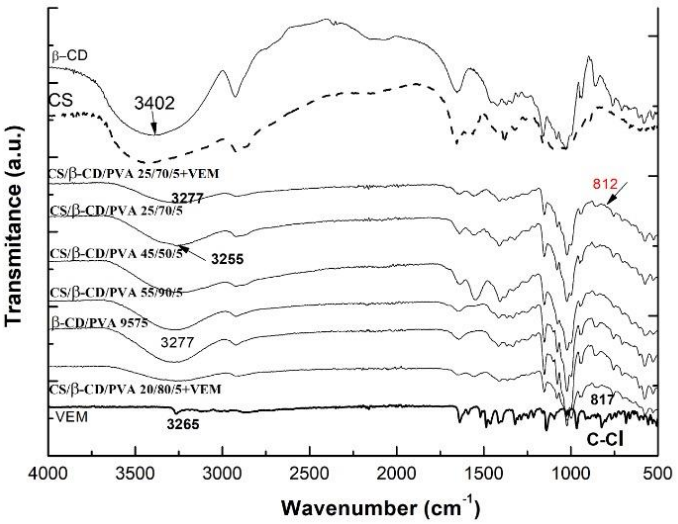

Fig. 2. ATR-FTIR spectra of the freeze-thawed hydrogels based on pure CS, β-CD, PVA, VEM and copolymers CS/β-CD/PVA loaded and unloaded with VEM

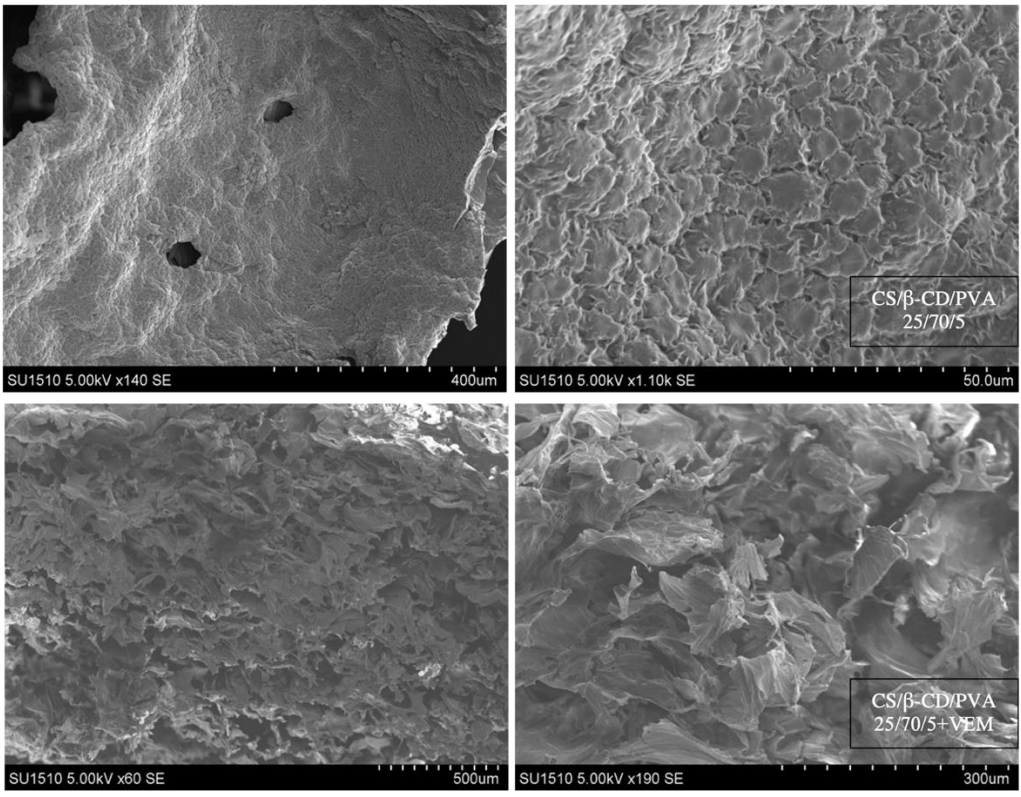
As shown within Figure 2, some characteristic vibration bands of β-CD were shifted in the inclusion complex spectra. The O-H stretching vibration from 3400 cm^{-1} of β-CD was shifted to 3250-3270 cm^{-1} within the spectra of the complexes. The shift of lower vibration bands indicated the formation of H-bonds between the OH groups of the biopolymers and PVA and thus proving the physical crosslinking.

The morphology of the prepared Hydrogels. For morphological analysis of the prepared matrices, we used Scanning Electron Microscopy (SEM) at various magnifications, as shown in figure 3.

As it is shown in the third figure, the hydrogels possess a continuous and stable network structure. Furthermore, all hydrogel samples exhibited large amounts of relatively loose and small pores, with irregular shapes and sizes providing great storage space for suitable active substances. The white dots with regular shape, that appeared in the loaded hydrogels, confirmed the presence of VEM. The roughness of the porous network that appeared on the microstructure surface of hydrogels exhibited in that figure may be attributed to the preparation and crosslinking process. The data was consistent with other SEM images found for that type of copolymer (20). The hydrogel based solely on β-CD and PVA was not taken into consideration for morphological analysis and further studies, because its very powdery texture after lyophilization was not adequate.



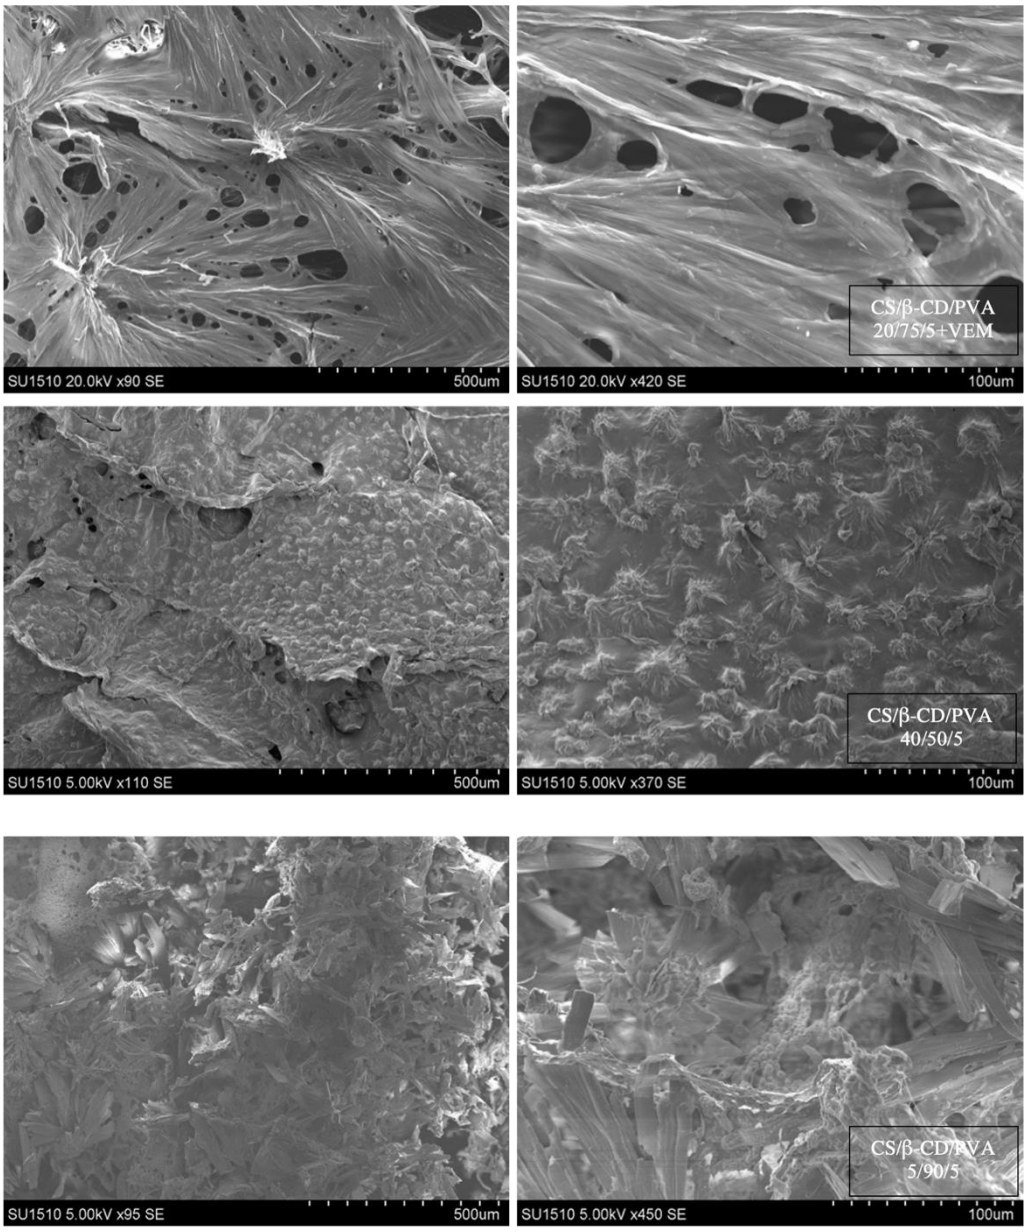


Fig. 3. SEM images for the prepared hydrogels at various magnifications

The porous aspect of the hydrogels was formed during the lyophilization process, due to the phenomenon of water sublimation from the matrix. CS/β-CD/PVA 25/70/5+VEM showed a more defined porous structure with well-interconnected pores. The CS/β-CD/PVA 20/75/5+VEM hydrogel also had a porous structure, but the diameter of the pores was larger and the walls were thicker.

The surface of the CS/β-CD/PVA 5/90/5 hydrogels was condensed with few observable pores. CS/β-CD/PVA 40/50/5 revealed spherical shapes on a smooth surface. Uncharged hydrogels exhibited a homogeneous, sponge-like morphology with well-interconnected pores.

Swelling Ability of CS/β-CD/PVA. The prepared matrices were designed to exhibit dual responsive behavior depending on various temperature and pH values at which we tested their swelling ability. The behavior of both control and drug loaded matrices were examined at various pH and temperature values as their properties may alter due to such physical changes (21).

Considering that the proposed matrices were aimed to release the active substance from a semi-solid form, the optimal pH was set at 5.5, since skin's pH is around 5.

From the graphs we observed the maximum swelling for acidic pH (being the value around which we are most interested in, considering the acidic microenvironment of tumors (22)) was around 800% due to the protonation of the free -NH_2 groups of CS, which demonstrated that optimal formulation for drug loading was CS/β-CD/PVA 25/70/5 or CS/β-CD/PVA 20/75/5 (their behavior was similar throughout the study). Similar pH-dependent swelling behavior for CS based matrices were reported in previous studies (17, 23).

Figures 4, 5 and 6 emphasize the dual responsiveness to the two stimuli, temperature and pH, for both the VEM-loaded and the control matrix. It can be observed that the loaded matrix showed a slightly lower swelling maximum, which demonstrated the incorporation of the active substance, the formation of electrostatic bonds between VEM and the polymer, and the prevention of a rapid burst release, which is not desirable, its aim being to achieve sustained drug release.

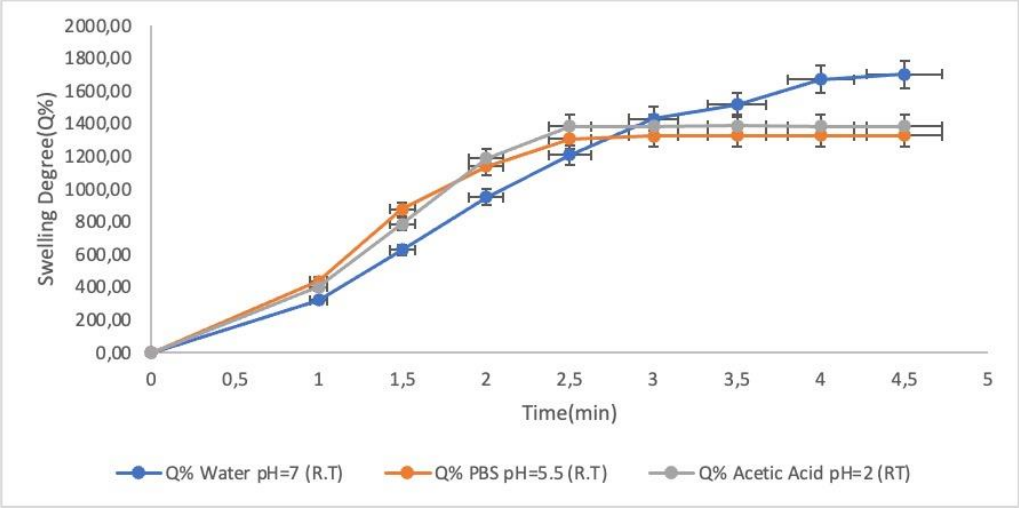

Fig. 4. Swelling behavior of the unloaded CS/β-CD/PVA 25/70/5 hydrogel at room temperature and various pH values

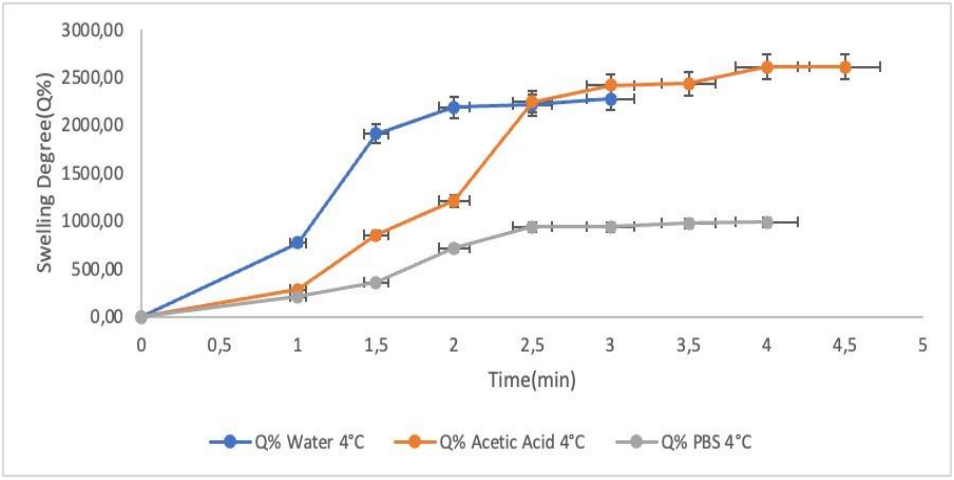

Fig. 5. Swelling behavior of the unloaded CS/β-CD/PVA 25/70/5 hydrogel at room temperature and various pH values

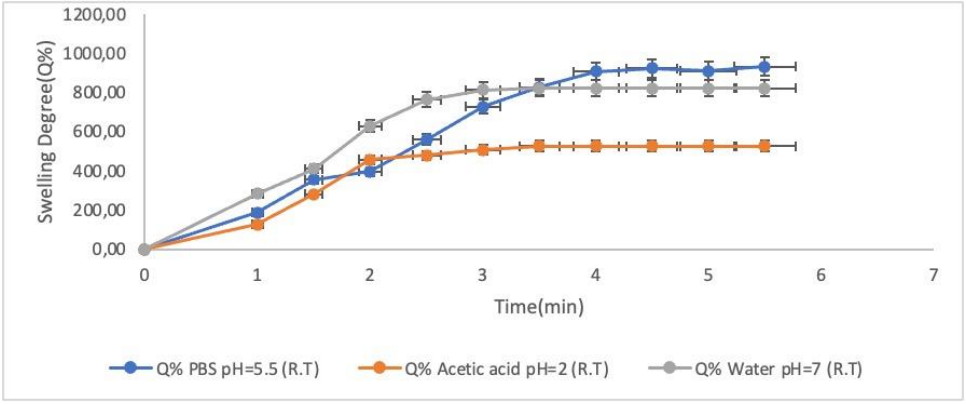

Fig. 6. Swelling behavior of the CS/β-CD/PVA 25/70/5 hydrogel loaded with VEM at room temperature and various pH values

Hydrogels are considered smart drug delivery systems precisely because of their ability to encapsulate drug substances that pose solubility problems, such as VEM. We have analyzed the drug loading capacity (DL) of our hydrogels, and we have found that for both loaded hydrogels DL was around 5.7 μg/mg, which led to 65-70% drug entrapment efficiency (DEE%), confirming a good capacity of drug encapsulation. The exact amounts and loading efficiencies are presented in table II.

TABLE II.
Hydrogels Loading VEM

Sample code	VEM loaded Hydrogel, μg/mg	VEM loading Efficiency, %
CS/β-CD/PVA 25/70/5 + VEM	5.7146	65.63%
CS/β-CD/PVA 20/75/5 + VEM	5.7672	70.93%

CONCLUSIONS

When it comes to achieving high levels of adherence to cancer treatment and drug selectivity towards cancer cells with little toxicity to healthy tissues and few unfavorable side effects, finding new smart drug delivery systems is the pillar of future therapeutic developments. The exploitation of local pH and the chemical potential of other stimuli responsive drug delivery vehicles combined with the physicochemical properties of therapeutic agents may lead to the discovery of new treatments to keep pace with the challenges brought by the increasingly aggressive forms of cancer that mankind is currently facing.

Among the various combinations of hydrogels we have experimented with, those obtained from combining chitosan, β-cyclodextrin and polyvinyl alcohol in two combination ratios (25/70/5 and 20/75/5) demonstrated excellent loading efficiency (65.63% and 70.93%, respectively).

Our proposed hydrogels have the potential to be used for that purpose, but future studies need to be performed to analyze *in vitro* and *ex vivo* release, as well as toxicity studies on melanoma cell lines.

JOB SATISFACTION AMONG ROMANIAN DENTISTS (Abstract). **Aim:** To analyze the determinants of career satisfaction among a group of dental practitioners. **Material and methods:** Cross-sectional survey conducted in 2016 in a group of 165 dentists working both in private dental practices and in the public sector in Iasi County, Romania. A 16-item questionnaire developed by us was sent via email, the response rate being 87.3%. Data were analyzed with the SPSS 18.0 system for Windows. **Results:** Seventy-six percent of the dentists consider themselves to be satisfied with their work, whereas 65% stated they are satisfied with their career. The aspects the dentists consider most important in their career are the income level (55%) and financial security (49%), while social insurance (6.6%) and continuous medical education (12.1%) were the less important. Fifty-five percent of the surveyed dentists believe that fatigue is the most important negative factor causing lack of job satisfaction, 62.9% are unhappy with their current wages and only 40.7% say that they have a monthly income over 1,000 euros; 52.1% of dentists would choose dentistry again as a career. **Conclusions**: The statistical analysis shows that the best predictor of job satisfaction is the income level, followed by working in a private dental office, level of autonomy and the lack of work-related fatigue. **Keywords**: JOB SATISFACTION, IASI, DENTISTS.

Dentistry in not only an attractive and interesting but also a difficult profession. Without forgetting the satisfaction and benefits brought by this profession, we must also mention the risk factors which may affect dentists' quality of life, like nervousness and depression (1). As in any other career, job satisfaction and motivation do not come only from the financial profit, but should be corroborate with other factors: stress reduction, a pleasant and calm atmosphere in the dental office, collaboration and motivation of the dental team which may result in increased performance (2).

That is why understanding career satisfaction/dissatisfaction of dental practitioners is of special interest both for the political decision makers to implement the best solutions for the oral health system, as well as for the dental students who should be informed about these issues. Numerous surveys on this topic have been published in the literature (3-12).

The aim of our study was to evaluate the aspects related to dentists' satisfaction with their professional career by considering the following factors: the legal status of

the dental practice, monthly income, and satisfaction with the performed medical activities, working relationships with the team members, with the patients and personal relationships.

MATERIAL AND METHODS

The cross-sectional survey was carried out in 2016 in Iasi County, Romania, using our own questionnaire. The questionnaire contained 16 open and closed-ended questions. Questions referred to the following aspects: overall satisfaction, delivery of care, income level, working environment and psychological factors (doctor-patient relationship, relationships with the staff, personal and professional time).

The study group included 165 dentists aged 26 to 54 years, mean age 36.02 ±8.033 years. They were divided into 2 categories: junior dentists aged 26-35 years, 95 (57%), and experienced dentists aged 36-54 years, 70 (43%); by gender 92 (55%) were women and 73 (45%) men. Of the 165 subjects, 102 (61.8%) were private practice dentists and 63 (38.2%) worked in the public sector as interns or specialists. Data were analyzed using SPSS 18.0 for Windows (SPSS Inc. Chicago, IL, SUA). Statistical significance of the bivariate analysis was assessed by the Pearson chi-square test, at the 0.05 level. The multiple logistic regression analysis was performed to determine the predictors of job satisfaction.

RESULTS

1. Overall satisfaction, delivery of care and earned income (tab. I)

TABLE I

Overall satisfaction, delivery of care and income value

Items	Participants		Chi-squre test p
	No.	%	
Overall professional satisfaction			
satisfied and very satisfied	125	76	p=0.001*
dissatisfied and very dissatisfied	40	24	
Work fatigue			
satisfied and very satisfied	75	45	p=0.122

> €1,000	67	40.7	

* statistically significant at p<0.05

2. Satisfaction with work environmental and psychological factors. Questions 9-12 assess the satisfaction with the activities in the dental office. Table II shows that significant statistical differences were recorded for: the evaluation of personal work performance, 90.9% of respondents considering it a key element for motivation in career, (p=0.001); the pleasant atmosphere in the dental office represents a satisfaction factor for 61.2% of respondents (p=0.021); the level of autonomy is appreciated by 77% of dentists (p=0.002). Insignificant statistical differences were recorded only for the appreciation of promotion opportunities (p=0.551). Another aspect that may generate satisfaction or dissatisfaction in the dental profession is represented by workplace relationships (tab. II). Significant statistic differences were obtained for answers to questions 13-15 (p<0.05): 71% of dentists were satisfied with their relationship with patients (p=0.002); 75% were happy to collaborate with their colleagues (p=0.001); 85% had good relationships with staff members (p=0.001). The answer to question 16 (Do you have enough free time to meet your personal needs?) had no statistical significance, p=0.331.

TABLE II

Satisfaction with work environmental and pshychological factors

Items	Satisfied and very satisfied		Dissatisfied and very dissatisfied		Chi-square test
	No.	%	No.	%	p
Professional apreciación	150	90.9	16	9.1	0.001*

DISCUSSION

The purpose of this survey was to understand if in today's Romania the dentist still has the *motivation* and *satisfaction* necessary to continue practicing dentistry, if there is still passion and wish to treat patients, as well as the related sacrifice. Other factors should not be omitted from

this equation, such as: the low socioeconomic status of some communities, a degree of rigidity of the education systems, and an inadequate fiscal and budgetary policy (13).

At the same time, the option to practice dentistry in other European countries, where the net salary is much higher, represents for the young graduate a fantastic opportunity for career development (14).

In this survey, we found that 76% of dentists consider themselves satisfied and very satisfied with their carrier, and 65% with their current workplace**.** Only 52.1% of the total 165 dentists would choose the same career again, 10.9% say that they consider a carrier change, with the percentage of the undecided ones being surprisingly high, namely 37%. This last variant may be interpreted as a lack of motivation towards their current career. One possible explanation might be that many dentists who participated in this survey are still at the beginning of their career and the problems they face in terms of low income and lack of opportunities may determine them to consider a career change. Satisfaction with the dentist career also involves analyzing the elements that young graduates consider essential at the beginning of their professional activity, of which the earned income was ranked first by 55% of the surveyed dentists. Unfortunately, post-graduate training, which is a key factor in career development, was appreciated by only 32.2% of the study participants. On the contrary, this motivation is considered a priority for dentists in India and Lithuania (3, 8). Another element considered to be less important for a successful career is the continuous medical education appreciated by only 12.1 % of the respondents. In India, Nayak (14) shows that a little less than half of the practitioners attended professional courses once in 6 months, 32.7% attended at least once in a year, and 22.1% attended rarely or never. It is known that the level of professional satisfaction among physicians in the light of earned income is dependent on the country level of economic development. In our survey, we found out that the best predictor for job satisfaction is a monthly income of more than 1,000 euro (OR=6.32)

In the literature, there are surveys showing that a low income is the most import factor of job dissatisfaction.

Dental professionals are exposed to many risk factors that may affect the quality of life, including physical exhaustion and stress with multiple effects on general health, behavioral disturbances and psychological symptoms. In our study, 55% of the surveyed dentists consider fatigue as a factor of dissatisfaction and from the logistic regression analysis we have found that lack of fatigue and stress at work can be a good predictor of career satisfaction. (OR = 2.01). If other specific factors, such as the stressful conditions, fatigue, lack of recognition and respect for the importance of the activity they carry out are added to these elements related to the poor funding of the public health system, migration or professional reorientation become a fully motivated action.

CONCLUSIONS

In our study, we found that financial security is the most important determinant of job satisfaction and a monthly income of more than 1,000 euro is the best predictor for the motivation to practice dentistry. Monthly income is considered the main cause of satisfaction/dissatisfaction, with 62.9% of dentists believing they should earn more. Other predictors of career satis-

faction include: degree of autonomy, private dental practice, lack of overwork and stress, as well as positive relationships with patients. A negative aspect was related to the lack of motivation for continuing medical education and ongoing professional training, aspects that dentists consider to be of little importance for career success.

MEASUREMENT OF DYNAMIC SOLICITED AREA, A PROPOSAL OF OBJECTIVE MEASURE FOR COMFORT EVALUATION IN TRANSTIBIAL PROSTHETICS (Abstract): Probably the most important factor in evaluating a patient's prosthesis is quality of life. This paper proposes an objective method for assessing patient's comfort by optimizing stump-sleeve-cup assembly, a correlation between the effort supported by skin areas upon intense stress during the movement cycle and the state of comfort**. Material and methods:** The changed work proposed as an objective measure was evaluated by simulation with processing of the image resulted from simulation with a finite element. We assume that the person wearing a prosthesis feels better (higher comfort and satisfaction) if prosthetic areas are less stressed (similarly to a shoe that we assume it is comfortable if it does not cause damage to the skin or if it fits properly. **Results:** The stump-prosthesis assembly is scanned and then, using contour detection routines, we determined the cluster set of points for each element (stump, tibia, fibula, skin, sleeve, and cup). We suggest a new objective measure for evaluating patient's comfort, a measure based on mathematical calculations. **Conclusions:** Validation of results is possible with a single method, the questionnaire method. In fact, almost all alternative comfort optimization and measurement methods lead to implementable solutions, but a medical validation is ultimately linked to the questionnaire, which is subjective. Some numerical simulations have been presented to illustrate theoretical analysis. These results are important and can provide a direction for future research. **Keywords:** FINITE ELEMENT, TRANSTIBIAL PROSTHESIS, GEOMETRIC ALGORITHMS, MECHANICAL WORK

Basic sensations from the neuroreceptors in the upper and lower limbs include pain, touch (pressure and vibration), temperature and muscle and tendon tensions (1). Generally, the term of discomfort refers to the problems related to matching the cup or sleeve with the patient's stump, therefore, it is not a basic feeling of the human body. Discomfort perception is basically a combination of two or more sensations that lead to a negative value of the patient's condition. It is worth noting that the feeling of discomfort is not always associated with pain, but pain will always make the patient feel uncomfortable. Age and geographical area and of course pros-

thetic materials influence the patient's comfort. The feeling of comfort or discomfort is usually assessed based on questionnaires (2, 3) that are mechanically validated, but inherently subject to medical validation both by those developing the questionnaire and deciding the questions and numerical scale (usually numbered from 0 to 10) (3), but also by the subject, who has a personal sensory perception, with subjective aspects in their answers to questions. Therefore, the assessment of discomfort is subjective and there are several methods that deal with this subject using measurement scales: categorical scale, interval-based scale and Borg's categorical rating scale. We have considered various scales, among which the most commonly used in hospitals and clinics is VAS (visual analogue scale), but there are reports stating that this scale is not sensitive to verbal descriptors separating pain intensity from a painful unpleasant feeling. An objective method of analyzing prosthesis quality can be a measure of deviation from the normal movement calculated by a method that considers the movement cycle and kinematic values of certain points on the human body (and prosthesis) that are qualitative characteristics of movement. Methods using kinematic indices of movement mainly seek to assess a (possibly pathological) situation compared to a normal situation (given by a reference group or person). There are many papers dealing with quantification of kinetic deviation from normal trends, but - to the author's best knowledge - there is only one paper that discusses the applicability of summaries on measuring the movement cycle of transtibial amputations (unilateral, a single limb) (4). The most used indexes are: Gillette (Gillette Gait index - GGI), movement profile score (Gait Profile Score - GPS), and movement analyze profile (Movement Analyze Profile - MAP). A summary of medical measurements, including techniques based on questionnaires and assessment of quality of life in patients wearing prostheses is presented in (5). In most cases, authors record and calculate kinematics using the Plug-in-Gait model (Vicon, Oxford Metrics) and placing of markers in compliance with the requirements for Helen Hayes set of markers (6). Markers are devices that generate light or reflect light on a dark background, making it possible to determine the trajectory of the bright sport using video image processing.

MATERIAL AND METHODS

A suggestion of objective measuring of comfort uses a principle based on energy minimization of patient effort, which reduces in a causal order the sensation of effort→ discomfort→ and increases the sensation of comfort. It assumes that the level of discomfort is given by the measure of work on the surface considered, which depends on the surface and force acting on it. Stump surface and skin-prosthesis interaction parameters are considered constant (coefficient of friction, moisture, temperature etc.). *C* is a closed curve (which does not intersect itself) *D* is the domain bounded by this curve. According to Green's theorem, the area bounded by *C* curve C is given by a double surface integral, difficult to apply for the pressure contour located on the stump, which has a shape curve very difficult to express in parametric form. The curve is approximated with a polygon (convex or concave), with a finite number of vertices, number given by the precision desired to approximate the area of the closed curve. For polygon area calculation, the topographic method described in sec-

tion (7) is suggested. We considered a polygon with n vertices in a plane (2D), which is covered in normal direction (counterclockwise). We note the vertices of the polygon with (x_0, y_0), (x_1, y_1),…., (x_{n-1}, y_{n-1}). Polygon area is given by the sum of determinants (7).

Basically, in case of images, the best possible approximation is at pixel level, while polygon vertices approximating the curve are in the center of the pixels on the contour (fig. 1).

$$(1) A = \frac{1}{2}\left\{\begin{vmatrix} x_0 & x_1 \\ y_0 & y_1 \end{vmatrix} + \begin{vmatrix} x_1 & x_2 \\ y_1 & y_2 \end{vmatrix} + \ldots + \begin{vmatrix} x_{n-2} & x_{n-1} \\ y_{n-2} & y_{n-1} \end{vmatrix} + \begin{vmatrix} x_{n-1} & x_0 \\ y_{n-1} & y_0 \end{vmatrix}\right\}$$

$$(2) A = \frac{1}{2}\left((x_0 y_1 - x_1 y_0) + (x_1 y_2 - x_2 y_1) + \ldots (x_{n-2} y_{n-1} - x_{n-1} y_{n-2}) + (x_{n-1} y_0 - x_0 y_{n-1})\right)$$

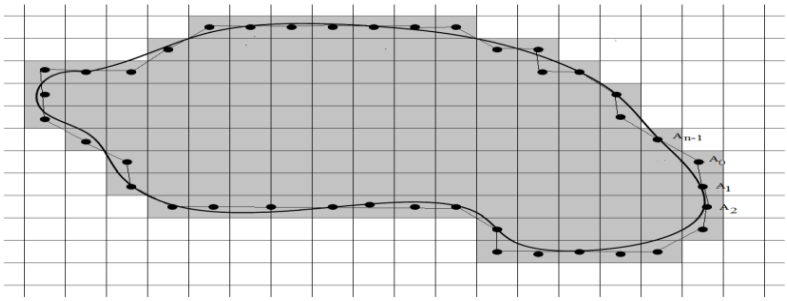

Fig. 1. Polygon area given by an extracted surface in pixels

Measure of the area depends on resolution, side of a rectangular pixel corresponds to *k* mm in real dimensions, therefore we have a A_t= k*A* scaling. On the other hand, in the 3D simulation image, if we approximate the residual limb with a truncated cone (common approximation in prostheses of lower limbs), what we measure is a projection of an area from the truncated cone on a flat surface that is the frontal plane viewed (fig. 2).

Developing a formula involves many calculations and is not justified for an algorithm with efficient computational effort, as this approach is a matter of future refining of the proposal in this paper (8).

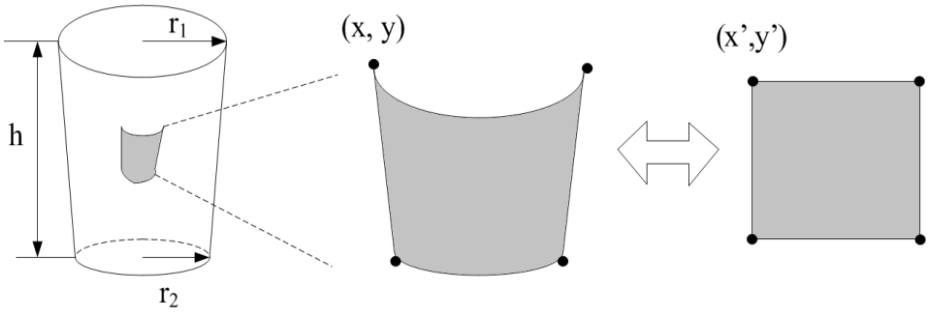

Fig. 2. A curvilinear rectangular surface on the truncated cone seen as distorted image

RESULTS

The stump-prosthesis assembly is scanned and then, using contour detection routines, we determined the cluster set of points for each element (stump, tibia, fibula, skin, sleeve, cup) and used NURBS curves for spatial reconstruction Non-uniform rational Basis spline – Non-uniform rational Basis spline - mathematical model for curves and surfaces, implemented in the CAD / CAE SolidWorks 2012 package. Elements are re-assembled into a 3D spatial reconstruction (fig. 3).

Bones and soft tissue, and skin and soft tissue are modelled as connected bodies (friction coefficient 1.0). The skin friction coefficient depends on the material used for the sleeve and cup, and varies generally between 0.4 and 0.8. A common modelling of the friction coefficient, where skin and soft tissues are considered homogeneous, isotropic bodies of 0.5 sleeve-skin and 0.7 sleeve-cup.

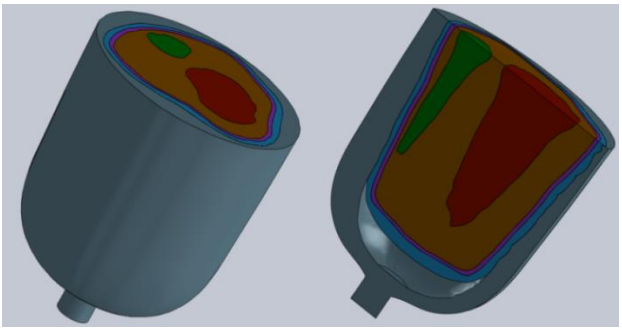

Fig. 3. Spatial reconstruction (3D) of the cup-prosthesis-stump ensemble and a section in this ensemble.

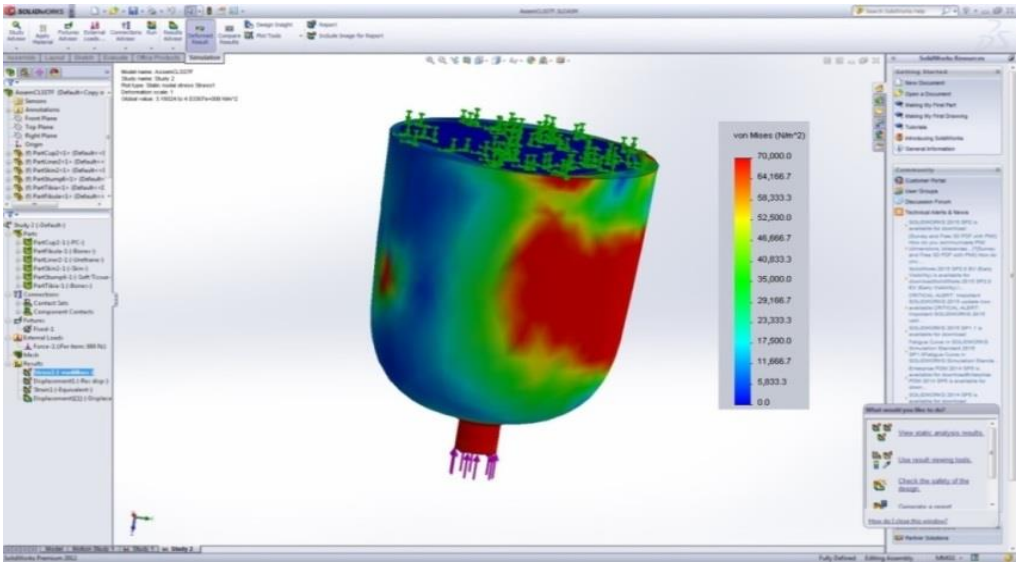

Fig. 4. Cup-prosthesis-stump ensemble with maximum pre-load and ground reaction force, F_{zmax} = 870 N, von Mises forces

The main stress at stump level in the stump-sleeve-cup interface is of a mechanical nature. The presence of two bone residues (tibia and fibula) and knee presence in leg amputation requires an approach and results different than trans femoral amputation, one bone residue and lack of the knee from previous doctoral thesis. Areas subject to intense stress are mainly those who raise medical issues, of structural integrity of the stump and ultimately essentially contribute to the patient's feeling of comfort/discomfort (fig. 4).

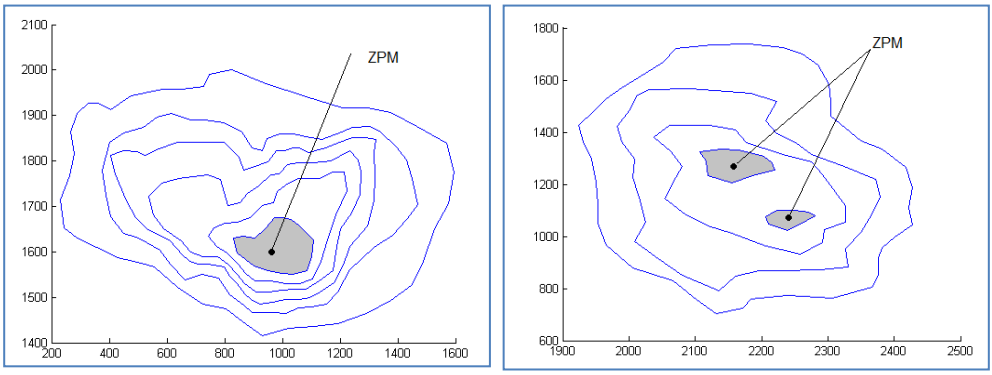

Fig. 5. Front transtibial location, transtibial amputation and local ZPM lateral position (maximum pressure area). Values on the horizontal and vertical axes are in pixels.

Note that in figure 5 (left-side) in all cases of simulation, there is only one island of maximum pressure in a large area, while in figure 5 (right-side) there are two islands (simulations also contained a situation where there were 3 islands) separated by a very small passage area. Basically, in this case we can consider that the maximum pressure per area is formed from a single zone, as in Figure 5 (left-side) and per **sum of areas** of two zones in figure 5 (right-side). Motivation is primarily of a medical nature, the larger the surface on which a maximum pressure is applied, the greater the likelihood that the surface in question develops skin lesions / deep wounds and therefore these areas should be identified and numerically evaluated.

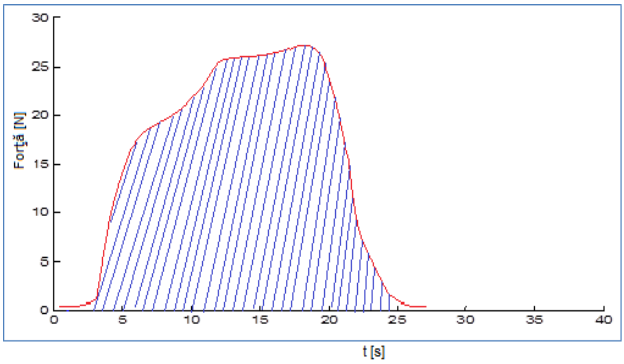

Fig. 6. Calculation $L_{FT.}$

We suggest a new objective measure for evaluating patient's comfort, a measure based on mathematical calculations and which is not modified by subjective assessments of the patient L_{FT} (fig 4).

$$(3) L_F = K\int_{x_0}^{x_f} \vec{F}\cdot d\vec{x} = K\int_{x_0}^{x_f} F\cos\alpha \cdot dx$$

$$(4) L_{FT} = K\int_{t_0}^{t_f} \vec{F}\cdot dt = K\int_{t_0}^{t_f} F\cos\alpha \cdot dt$$

In the above formulas, the force acts perpendicularly on the stump, therefore α =1, and the movement speed is approximately constant. K is a constant associated with the area and a first approximation is K=A·*v*, where *v* is the speed. In our case, speed is constant and we approximate with a *v* = *b* constant. This is explained by the fact that work on a surface is greater in the broader sense of patient comfort issue is all the greater as the surface is larger.

$$(5) L_{FT} = K\cdot b\cdot\int_{t_0}^{t_f} F(t)\cdot dt$$

$$(6) L_{FT} = K\cdot b\cdot\int_{t_0}^{t_f} |F(t)|\cdot dt$$

In the above formulas L_{FT} is the measure inspired from work, α- the angle of the acting force, *v*- speed (equal to constant *b*), *t* – time, *A* area covered by the sensor as a circular disc, *K* a constant and F the force as absolute value. We considered a movement (on the treadmill) at constant acceleration *a* = *dv*/*dt*) with a complete movement cycle over approximately 2.4 m. Current data were collected from a group of two patients with a set of 32 repetitions of a complete movement cycle (8 normal gait cycles, 8 cycles down the stairs, 8 cycles up the stairs and 8 rest cycles). We will assign a greater state of comfort as L_{FT} is lower. The results showed that for patient A the optimum is given by L_{FTmin} = 875.244 for the soft Pelite-PP/PE sleeve-cup combination, and for patient B, the optimum is given by L_{FTmin} = 915.244 for the soft Pelite-Polypropylene sleeve-cup combination. Corresponding values are 4 and 5 (maximum) on the comfort scale given by the questionnaire method commonly used to assess the comfort status of a person wearing a prosthesis, which creates the prerequisites for a possible effective evaluation method of comfort. Of course, all results must be medically validated, but in this area there are known cumbersome procedures which require time, and the gap between research and practical applications is sometimes very large. The results were consistent with the theory (and the results published in the literature by other authors) and, in our opinion, better than the questionnaire method. This assumption is based on two and four series of short tests applied to the person who presented a difference between the value of comfort level on PEQ scale and the objective scale. Two cases were with A combination and two with B combination. The patient was informed on the tests with combinations of material A - 3 tests and B - 1 test (the patient was informed for each test). Surprisingly, for the B combination, the questionnaire method in a test was 4 and in the other it was 5, suggesting that the proposed method is more consistent.

CONCLUSIONS

In this article measuring of comfort uses a principle based on energy minimization of patient effort and It assumes that the level of discomfort is given by the measure of work on the surface considered. The

stump-prosthesis assembly is scanned and then, using contour detection routines, we determined the cluster set of points for each element. Elements are re-assembled into a 3D spatial reconstruction and we suggest a new objective measure for evaluating patient's comfort, a measure based on mathematical calculations.

In this paper, we can consider that the maximum pressure per area is formed from a single zone, and per sum of areas of two zones and the results were consistent with the theory and, in our opinion, better than the questionnaire method.

SYNTHESIS OF HIERARCHICAL CuO NANOSTRUCTURES: BIOCOMPATIBLE ANTIBACTERIAL AGENTS FOR GRAM-POSITIVE AND GRAM-NEGATIVE BACTERIA

Copper Oxide is one of the important materials among other antimicrobial agents such as silver, zinc oxide, or titanium dioxide. CuO nanostructures have stimulated great interest in the field of environmental remediation because of their important characteristics which include: high stability, structural properties, antimicrobial activity. The novelty of this study is the biocompatibiliy determination of nanostructured CuO. The findings of the present work proved that the prepared CuO nanostructures are highly stable in aqueous solution and biocompatible in blood. They also exhibited pronounced bactericidal activity towards both Gram positive and Gram negative bacteria (Sonia S, Jayasudha R, Jayram ND, et al. Synthesis of hierarchical CuO nanostructures: Biocompatible antibacterial agents for Gram-positive and Gram-negative bacteria. *Current Applied Physics* 2016, 16: 914-921).

CHANGES IN SOME DIVALENT CATION CONCENTRATION IN AN EXPERIMENTAL RAT MODEL OF GENTAMICIN-INDUCED ACUTE RENAL FAILURE (Abstract) **Aim:** The changes in divalent cations concentration were assessed in and experimentally gentamicin-induced renal failure in white Wistar rats. **Material and methods**: The white male Wistar rats were distributed into 4 groups of 7 animals each and were treated intraperitoneally as follows: Group I (Control): distilled water in a volume of 0.5ml/100g rat/day for10 days; Group II (Ge): gentamicin 80 mg/kbw/day for 7 days; Group III (Ge+Zn): gentamicin 80 mg/kbw/day for 7 days and ZnCl2 5 mg/kbw/day for 10 days prior to administration of Ge and then another 7 days simultaneously with Ge administration; Group IV (Zn): ZnCl2 5 mg/kbw/day for 17 days. Before starting the experiment (I_0) and at 3, 7 and 10 days after the first Ge administration, magnesium, copper and zinc plasma concentrations and urinary magnesium levels were determined. **Results**: Zn administration significantly decreased ($p<0.001$) plasma Mg concentrations in Ge+Zn group compared to Ge group after 7 days in the experiment, and induced a lower urinary elimination of Mg in Ge+Zn group ($p<0.05$) than in Ge group ($p<0.01$). Also, Zn induced a slight augmentation of Cu concentration in Ge+Zn group ($p<0.05$) compared to Ge group after 7 and 10 days. **Conclusions**: The variation in divalent cation concentrations in the context of renal diseases may be helpful for an early diagnosis and effective alternative therapeutic measures. **Keywords**: DIVALENT CATIONS, RAT MODEL, ACUTE RENAL FAILURE, GENTAMICIN.

The kidney plays an important role in the homeostasis of divalent cations (1). This adjustment is processed at different levels of the nephron involving the participation of ion channels and some transporters.

Zinc (Zn) is the second most abundant metal in the body, after iron, and is the only metal that can be found in all types of enzymes. Zn, being found in all tissues of the body, plays a role in immune system function, tissue repair processes, protein production, DNA synthesis and cell division. Severe Zn deficiency can induce immune system disturbances, alteration of macrophage and neutrophil functions, apoptosis and impairment of complement activity (2, 3).

Magnesium (Mg), the second most common cation in the extracellular space after potassium (K), plays an essential role in physiological cellular processes due to its ability to form complexes with the important intracellular anionic ligands (especially with adenosine triphosphate – ATP), and its capability to compete with calcium for membrane sites. It is known that over 300 enzymatic reactions are dependent on the presence of Mg, those involved in ATP generation and utilization (4).

Copper (Cu) is an essential trace element, being stored primarily in the liver, with small amounts also present in the brain, heart, kidney and muscles. Cu is involved in the functioning of some essential enzymes. Cu maintains the resistance of the skin tissue, blood vessels, epithelial and connective tissues. It also has a major role in the synthesis of hemoglobin, myelin, melanin, and in maintaining of the thyroid gland normal functions (5).

In the present study, we aimed at evaluating the changes in divalent cation concentration, in experimentally gentamicin-induced renal failure in white Wistar rats.

MATERIAL AND METHODS

The following substances were used in the experiment: gentamicin solution for injection 80mg/2ml (Krka, Slovenia), zinc chloride (ZnCl2) ≥98% (Sigma-Aldrich Corporation), distilled water (Sicomed Romania).

Male white Wistar rats (weighting 210-320g), housed in rooms with controlled temperature (22-24°C) and constant 12 hours' light-dark cycle, and kept in metabolic cages with free access to water and standard food, were monitored for 24-hour water intake and urine output.

The animals were distributed into 4 groups of 7 animals each, treated intraperitoneally (i.p.) as follows: Group I (Control): distilled water in a volume of 0.5ml/100g rat/day for10 days; Group II (Ge): gentamicin 80mg/kbw/day for 7 days; Group III (Ge+Zn): gentamicin 80 mg/kbw/day for 7 days and ZnCl2 5 mg/kbw/day for 10 days prior to administration of Ge and then another 7 days simultaneously with Ge administration; Group IV (Zn): ZnCl2 5 mg/kbw/day for 17 days.

Blood samples were collected from retro-orbital plexus of anaesthetized animals, before starting the experiment (I_0) and at 3, 7 and 10 days after the first administration of the nephrotoxic agent to determine the magnesium, copper and zinc plasma concentrations. Urine samples were collected at the same intervals as the blood samples, to measure the calcium and magnesium levels.

Cu and Zn plasma concentrations were determined by atomic absorption spectrophotometry using an Analyst 600 Atomic Absorption Spectrophotometer (Perkin Elmer), a AS-800 Graphite Furnace Autosampler, and a copper or zinc HCL (Hallow Cathode Lamp). A Randox kit and a Xylidyl blue colorimetric method were used to measure serum and urinary magnesium levels.

All data were presented as mean ± standard deviation (SD) of mean for 7 animals in a group. P-values less than 0.05 were considered statistically significant. Data were processed using one-way ANOVA method and Tukey's test.

The experimental protocol was implemented in compliance with the instructions of the "Grigore T. Popa" University of Medicine and Pharmacy Iaşi Committee for Research and Ethical Issues, per the Re-

search Law 206/27.05.2004 regarding the conduction of scientific research, technological development and innovation and the actual European legislation.

RESULTS

The biochemical analysis revealed a statistically significant increase in serum Mg levels at 7 days compared with I_0 in Ge group ($p<0.01$) and Ge+Zn group ($p<0.05$). A reduction in Mg levels was recorded at 7 days (after 17 days of Zn administration), statistically significant compared with I_0 in Zn group ($p<0.01$). The administration of Zn significantly diminished ($p<0.01$) the plasma Mg concentrations in Ge+Zn group compared to Ge group at 7 days in the experiment (tab. I).

TABLE I

Variation in plasma Mg concentration (mg/dl) in Ge, Zn and Ge+Zn groups

Lot	initially (I0)	3 days	7 days	10days
Ge	2,35±0,26	2,31±0,07	*4,31±0,29	#2,30±0,06
Ge+Zn	2,36±0,17	2,44±0,14	*;^2,97±0,18	#2,45±0,18
Zn	2,46±0,20	2,52±0,41	*1,86±0,25	2,36±0,15
Control	2,39±0,08	2,43±0,18	2,40±0,14	2,45±0,13

* $p<0.01$ vs. I_0 and Control; #$p<0.05$ vs. 7 days; ^ $p<0.01$ vs. Ge

Significant increases ($p<0.01$) in serum Cu levels were recorded in Ge+Zn group, but not in Ge group after 3, 7 and 10 days, compared to the initial moment I_0.

The laboratory determinations highlighted a progressive decrease in plasma Cu values, statistically significant ($p<0.01$) at 7 days, compared with I_0 in Zn group (after 17 days of $ZnCl_2$ administration). The treatment with Zn induced a significant augmentation of Cu concentration in Ge+Zn group ($p<0.01$), compared to Ge group at 7 and 10 days in rats with experimentally gentamicin-induced acute renal failure (tab. II).

TABLE II

Variation in plasma Cu concentration (µg/dl) in Ge, Zn and Ge+Zn groups

Lot	I0	3 days	7 days	10 days
Ge	139,30±5,93	148,59±5,88	144,37±6,10	145,7±4,61
Ge+Zn	127,78±8,09	*146,94±11,4	*;^175,37±9,03	*;^165,62±6,68
Zn	125,28±13,89	119,38±10,33	*98,86±13,13	128,58±13,04
Control	148,06±6,75	145,95±4,67	148,23±2,45	143,60±5,59

*$p<0.01$ vs. I_0; ^$p<0.01$ vs. Ge

Our investigation showed a statistically significant elevation ($p<0.01$) of serum Zn levels at 3, 7 and 10 days compared to I_0 in Ge and Ge+Zn groups. The treatment with Zn was associated with a significant increase of plasma Zn levels in Ge+Zn group compared with Ge group at 3, 7 and 10 days in the experiment (tab. III).

The biochemical analysis detected an elevation of Mg urinary excretion, statistically significant at 7 and 10 days compared to I_0 in Ge group ($p<0.01$). In Ge+Zn group

it was also registered an increased excretion of urinary Mg at 7 days compared to I_0 ($p<0.01$). The administration of Zn resulted in a lower urinary elimination of Mg in Ge+Zn group than in Ge group ($p<0.01$) at 10 days (fig.1).

TABLE III
Variation in plasma Zn concentration (µg/dl) in Ge, Zn and Ge+Zn groups

DISCUSSION

Zn is considered an important element necessary for the physiological function of cell signaling, and influences the redox status, enzyme activity, gene transcription, energy metabolism, cell cycle, apoptosis and cell proliferation. Zn deficiency increases the levels of nitric oxide and superoxide radicals by inhibiting the N-methyl-D -aspartate receptor (6, 7).

Literature data suggest that, besides the action of highly reactive radicals, another mechanism of Ge nephrotoxicity is represented by the changes of trace elements in the kidney (8). In our study, Zn loading resulted in a significantly lower increase of serum Mg in Ge+Zn group compared to Ge group (2.97 ± 0.18 mg/dl *vs* 4.31 ± 0.29 mg/dl). Similarly, after Ge administration, on day 7 we recorded elevated serum Mg levels as compared with I_0. However, Zn administration did not significantly affect

serum Ca concentration in Ge+Zn group compared to Ge group.

The values showed no significant change in plasma Cu following Ge administration, but Zn treatment generated increased Cu concentration in Ge+Zn group compared to Ge group (175.37 ± 9.03 μg/dl *vs.*144.37 ± 6.1 μg/dl at 7 days). Plasma Cu values showed an increase in the group treated with Ge compared to I_0, and Zn charge resulted in higher plasma Zn levels in Ge+ Zn group compared to Ge group (189.49±16.26 μg/dl *vs.* 158.74±8.26 μg/dl at 7 days).

Mg modulates the contractility and electrical activity of myocardial cells, and the conduction system that influences the transport of ions (sodium, potassium, calcium) in the sarcolemma. Mg can also influence vascular smooth muscle tone. The exact physiological mechanism that regulates plasma Mg concentration is not completely elucidated. It seems that serum Mg is regulated through a dynamic mechanism and interaction between the transport in the kidney, intestine and bones (9).

Approximately 95% of ultra-filtered Mg is reabsorbed in the kidney: 25-30% in the proximal tubules, about 60-65% is reabsorbed in the ascending loop of Henle, and 5% in the distal segment. Mg excretion is controlled primarily by serum Mg concentration (10).

Hypermagnesemia is associated with an increase in Mg excretion which can be up to 100% of the filtered amount. Literature data confirm that Ge can generate renal Mg loss through a furosemide-like mechanism, by inhibiting the paracellular transport in the ascending loop of Henle (11).

Copper can act both as an antioxidant and as a pro-oxidant. As an antioxidant, it removes or neutralizes free radicals and reduces the damage caused by these agents, which can promote pathological processes through interaction with genetic material. When acting as a pro-oxidant, Cu can induce the generation of free radicals and contribute to the development of such diseases as Alzheimer's disease. Normal Cu homeostasis, as well as other mineral balance (Zn, Mg), is important for maintaining health (12).

Some studies investigated the Cu/Zn imbalance in Cu deficiency in rats. In case of Cu deficiency, decreased activity of superoxide dismutase and increased malondialdehyde levels compared to normal values were recorded (13).

CONCLUSIONS

Divalent cations homeostasis is essential for the proper functioning of the entire organism. Our study suggested the importance of taking in consideration the variation in concentrations of these cations in the context of renal diseases, being possibly helpful for early diagnosis and effective alternative therapeutic measures.

NEWS

CALCIUM SUPPLEMENTS MAY AFFECT THE CORONARY ARTERIES

This is the conclusion of a recent article published in Journal of American Heart Association. This result represents part of a bigger study conducted in six research American universities, the Multi-Ethnic Study of Atherosclerosis. The researchers used dietary questionnaires and CT scans spanning 10 years apart to asses the daily calcium intake (either as supplements or food) and the calcium score. The results showed that supplement users have a 22% higher risk of developing coronary artery disease (defined as a rise of the calcium score over the 10 years) than the subjects with a high dietary intake of calcium. It is still unclear why taking the same amount of calcium as supplement is more harmful, but the ipothesis takes into account the form of calcium that can be differently absorbed (calcium salt in supplements) and the inability of the body of processing a large dose of calcium all at once (John J.B. Anderson, PhD; Bridget Kruszka, MPH et al. Calcium Intake From Diet and Supplements and the Risk of Coronary Artery Calcification and its Progression Among Older Adults: 10-Year Follow-up of the Multi-Ethnic Study of Atherosclerosis (MESA). *J Am Heart Assoc*. 2016; 5:e003751).

INSIGHTS ON THE SOCIAL PERCEPTION OF MENTALLY DISABLED CHILDREN (Abstract): **The aim** of the research is to analyze the social perception of mentally disabled people and of attitudes toward them among teachers, according to certain variables such as subjects' age, gender, type of education and degree of interaction with mentally disabled people, understood as work experience with mentally disabled children. **Material and methods**: A number of 120 teachers (44 men and 76 women) answered to a 26 items of *Scale of perceptions and attitudes regarding mentally disabled people* investigating the following dimensions: the concept of mental disability, the image of mentally disabled people, integration into society, education. Several variables were taken into consideration. Result analysis and interpretation has been performed by means of the specialized psychological statistics software *SPSS 23* for Windows. **Results**: female teachers (M=17.00) have a significantly more favorable attitude - t (118)=-3.75, p=.001 than men (M=12.25) who work as teachers and younger teachers and those with no experience with children with mental disability have a more favorable attitude toward mentally disabled people than their colleagues. **Conclusions**: Age, experience with mental disabled children and gender of teachers are influencing the perception and the attitudes regarding people with disability. **Keywords**: CHILDREN, MENTAL DISABILITY, SOCIAL PERCEPTION, TEACHER

Working with children with mental disability is a demanding task and people who are involved in special education have to prove not only emotional balance, empathy, intellectual capability, pedagogical tasks or good training in working with a special category of children, but they have to deal also with their personal limits. Teachers' attitudes are crucial to the success of inclusion programs for children with special needs (1) and the consequences of the disability on child's life and family are extremely important (2). Family involvement is necessary (3) and in majority of cases parents are becoming home teachers too, so a good collaboration between teachers and caregivers are assuring a better development for the children in need (4,5,6).

Both education and contact were revealed to have had positive effects on reducing stigma for adults and adolescents with a mental illness and to assure a better

social integration (7). Some studies pointed that teachers are concerned about integrating children with special needs in their classrooms (8) even if they had positive feelings about them.

The aim of our research is to emphasize the social perception of mentally disabled people and of attitudes toward them among teachers, according to certain variables such as subjects' age, gender, type of education and degree of interaction with mentally disabled people, understood as work experience with mentally disabled children.

MATERIAL AND METHODS

In order to achieve the aim, we have built (starting from the results of the qualitative analysis obtained following a questionnaire with open answers) the *Scale of perceptions and attitudes regarding mentally disabled people*. The open answer questionnaire on which the instrument of our research has been built has included the investigation of the following dimensions: the concept of mental disability (cognitive vs. global perspective), the image of mentally disabled people (characteristics, capacities, disabilities), integration into society (social perception, support measures, support institutions, vocational options), education (types of schooling, adaptation problems: relational, behavioral, educational and perspectives after graduation).

After pretesting and eliminating items with an internal consistency coefficient lower than 0.60, 26 items remained, corresponding to four subscales: *capacity for social integration* - 6 items with Cronbach's alpha=0.91), *positive characteristics* - 3 items with Cronbach's alpha=0.73), *negative characteristics* - 9 items with Cronbach's alpha=0.75), *attitudes toward mentally disabled people* - 8 items with Cronbach's alpha=0.71. The score for each scale has been obtained by adding up the values assigned to the items, values which can be assessed on a scale of 1 to 5. The items ranked in reverse are: 7, 14, 15, 16, 17, 25.

The target population of the study, from which the batch of 120 subjects has been extracted by random sampling, consists of teachers with ages ranging 23-35, 36-50 and over 50 years old; subject samples have been small and independent.

Thus, by the gender variable, the batch includes 44 men and 76 women. By the age variable, the batch includes 26 subjects included in the category 23-35, 65 subjects with ages 36-50 and 29 subjects with ages over 50. By variable “level of interaction with mentally disabled people”, the batch includes 70 teachers who have not interacted with such people, 31 subjects who have under 10 years' experience working with mentally disabled children and 19 subjects with over 10 years' experience. 70 subjects work in primary education and 50, in secondary education.

The research has been carried out in two regular schools (where mentally disabled children are also integrated) and in one special school. The questionnaire has been submitted individually, and subjects' anonymity has been ensured.

Result analysis and interpretation has been performed by means of the specialized psychological statistics software *SPSS 23* for Windows, trial version, downloaded from the official IBM website. The following statistical analyses have been performed:

- the Student's t-test for independent samples, determining the significance of the difference between means according to variables “gender” and “type of education”.

▪ the one-way ANOVA (single factor) for comparing means according to variables "age" and "level of interaction".

RESULTS

The influence of subjects' gender on their social perception of mentally disabled people

Applying the t-test for independent samples, we have analyzed the results obtained by male and female subjects. According to the data obtained, we notice no statistically significant differences between male and female subjects in variable "capacity for social integration", but there are statistically significant differences between the mean obtained by women (MF=10.4) and that obtained by men (MM=8.9) in variables "positive characteristics" (t (118)=-3.12, p=.002 < 0.05) and "negative characteristics" (t (118)=3.06, p=.003 < 0.05; MF=26.7, MM=31.2), in that the mean obtained by women is significantly lower than that of men concerning negative characteristics and significantly higher concerning positive characteristics. Moreover, in terms of the attitude to mentally disabled people, female teachers (M=17.00) have a significantly more favorable attitude (t (118)=-3.75, p=.001 < 0.05) than men (M=12.25) who work as teachers. Results are presented in Table I.

TABLE I

The influence of subjects' gender on their social perception of mentally disabled people

Dimensions	Gender	N	Mean	Standard deviation	t	p
capacity for social integration	M	44	15.4	4.8	-.092	.927
	F	76	15.5	4.5		
positive characteristics	M	44	8.9	2.6	-3.12	**.002**
	F	76	10.4	2.4		
negative characteristics	M	44	31.2	7.8	3.06	**.003**
	F	76	26.7	7.5		
attitude to mentally disabled people	M	44	12.25	5.8	-3.75	**.001**
	F	76	17.00	7.9		

The influence of the type of educational system that subjects are involved in (primary and secondary) on their social perception of mentally disabled people

Applying the t-test for independent samples, we have analyzed the results obtained by subjects involved in primary and secondary education (tab. II). There are statistically significant differences between subjects according to variable "type of education" (t (118) =3.082, p=.003 < 0.05), in that teachers working in primary education (M=17.00) have a significantly more favorable attitude toward mentally disabled people, compared to those working in secondary education (M=12.82). In addition, teachers working in primary education have a social perception with more positive characteristics, obtaining significantly higher means in subscales "capacity for integration" (t (118)=4.674, p=.000; MP=17.02, MG=13.32) and "positive characteristics" (t (118)=5,577, p=.000; MP=10.84, MG=8.48) and significantly lower means in subscale "negative characteristics" (t (118)=-5.103, p=.000; MP=25.55, MG=32.36), compared to their colleagues working in secondary education.

TABLE II

The influence of the type of education that subjects are involved in (primary and secondary) on their social perception of mentally disabled people

Dimensions		N	Mean	Standard deviation	t	p
Capacity for social integration	Primary school	70	17.02	4.4	4.674	**.000**
	Secondary school	50	13.32	4.1		
Positive characteristics	Primary school	70	10.84	2.2	5.577	**.000**
	Secondary school	50	8,48	2.3		
Negative characteristics	Primary school	70	25.55	6.6	-5.103	**.000**
	Secondary school	50	32.36	7.8		
Attitude to mentally disabled people	Primary school	70	17.00	7.2	3.082	**.003**
	Secondary school	50	12.82	7.3		

The influence of teachers' age on their social perception of mentally disabled people and their attitude to the latter

Applying the one-way ANOVA, we have analyzed the effect of the age variable on the social perception of mentally disabled people and on the attitude to them.

According to the data obtained, we notice that age has a statistically significant effect only on assessing the capacity for integration (F=11.644, p=.000) and the positive characteristics of mentally disabled people (F=7.643, p=.001). When it comes to assigning negative characteristics and to subjects' attitude toward these people, age has no significant influence.

After carrying out the Bonferroni test, we highlighted that there are statistically significant differences on the assessment of mentally disabled people's capacity for integration between subjects aged between 23-35, those aged between 36-50 and those over 50 years old. Thus, teachers aged 23-35 years old consider that mentally disabled people have a higher capacity for integration than subjects from the other two age groups (M (23-35)–M (36-50) =4.21, p=.000<.05; M (23-35)–M (over 50) =5.10, p=.000 < .05).

There are no statistically significant differences between age groups 36-50 and over 50 concerning the assessment of mentally disabled people's capacity for integration (tab. III).

Regarding the assignment of positive characteristics, we notice statistically significant differences between the 23-35 age group, compared to the other two groups. Thus, teachers aged between 23 and 35 assign more positive characteristics to mentally disabled people compared to their colleagues in the other two age groups (M (23-35)–M (36-50) =1.53, p=.022 < .05; M (23-35)–M (over 50) =2.54, p=.001 < .05).

There are no statistically significant differences between the 36-50 and over 50 age groups, when it comes to assigning positive characteristics to mentally disabled people.

The influence of variable "level of interaction" on teachers' social perception of mentally disabled people and their attitude to the latter

Applying the one-way ANOVA, we have analyzed the effect of variable "level of interaction" (experience working with

mentally disabled children) on the social perception of mentally disabled people and on the attitude to them. According to the results obtained (tab. IV), the level of interaction also has a significant effect on the social perception of mentally disabled people and on the attitude toward them.

Thus: capacity for integration: F(2,117) =19.266, p=.000<.05; positive characteristics: F(2,117)=19.403, p=.000<.05; negative characteristics: F(2,117)=17.129, p=.000<.05; attitude toward mentally disabled people: F(2,117)=12.091, p=.000< .05.

After carrying out the Bonferroni test, we may note the following differences between groups in table V.

TABLE III

The influence of teachers' age variable on their social perception of mentally disabled people and their attitude to the latter

Dependent Variable	(I) age	(J) age	Mean Difference (I-J)	Std. Error	Sig
Capacity for social integration	23-35	36-50	4.21538*	.99280	**.000**

There are statistically significant differences in what concerns the assessment of the capacity for integration of mentally disabled people between subjects who have never worked with mentally disabled children and those who have worked with them for under 10 years or over 10 years. Thus, teachers who have not interacted with mentally disabled children consider that mentally disabled people have a higher capacity for integration than assessed by their colleagues with experience working with these children (M (none)–M (under 10 years) =3.85, p=.000 < .05 / M (none)–M (over 10 years) =5.63, p=.000 < .05). There are no statistically significant differences between teachers with less than 10 years of experience working with mentally disabled children and those with over 10 years of experience, in what concerns the assessment of the capacity for integration of mentally disabled people.

Regarding the assignment of positive characteristics, we noticed statistically significant differences between teachers who have never interacted with mentally disabled children, compared to the other two groups. Thus, teachers who have never interacted with these children assign more positive characteristics to mentally disabled people than their colleagues in the other two groups (M (never)–M (under 10 years) =2.41, p=.000 <.05 / M (never)–M (over 10 years) =2.82, p=.000 < .05).

There are no statistically significant differences between colleagues with under 10 years of experience working with mentally disabled children and those with over 10 years of experience, concerning the assignment of positive characteristics to mentally disabled people.

In terms of assigning negative characteristics, there are statistically significant differences between teachers who have never interacted with mentally disabled children, compared to the other two groups. Thus, teachers who have never interacted with these children assign fewer negative characteristics to mentally disabled people than their colleagues in the other two groups (M (never)–M (under 10 years) =-6.66, p=.000 < .05/ M (never)–M (over 10 years) =- 8.83, p= .000 < .05).

There are no statistically significant differences between teachers with under 10 years of experience working with mentally disabled children and those with over 10 years of experience, concerning the assignment of positive characteristics to mentally disabled people.

In what concerns the assignment of negative characteristics, there are statistically significant differences between teachers who have never interacted with mentally disabled children, compared to the other two groups. Thus, teachers who have never interacted with these children assign less negative characteristics to mentally disabled people compared to their colleagues in the other two groups (M (never)–M (under 10 years) =-6.66, p=.000 < .05; M (never)–M (over 10 years) =- 8.83, p=.000 < .05).

There are no statistically significant differences between teachers with under 10 years of experience working with mentally disabled children and those with over 10 years of experience concerning the assignment of negative characteristics to mentally disabled people.

When it comes to the attitude toward mentally disabled people, we notice from the results obtained that there are statistically significant differences between teachers who have never interacted with mentally disabled children, compared to the other two groups. Thus, teachers who have never

interacted with these children have a more favorable attitude toward mentally disabled people than their colleagues in the other two groups (M (never)–M (under 10 years) =5.42, p=.001 <.05 / M (never)–M (over 10 years) =7.47, p=.000 < .05).

There are no statistically significant differences between teachers with under 10 years of experience working with mentally disabled children and those with over 10 years of experience, concerning the attitude toward mentally disabled people.

DISCUSSION

Working with children with disabilities demand a lot of determination. It is not about the intellectual disability because studies proved that there are a lot of differences between children with or without mental disability, not only the mental aspects: social problems, family problems, attention problems and aggressiveness (10). The influence of the environmental on the quality of life of children with such problems is proved and together with family members, medical team, friends, policy makers, school members must assure a protective (safe) and adapted (good integration, also in public schools) place for them (11). The issue regarding including children with disabilities in special or normal schools has been generated a lot of disputes, shaping both positive and negative effects on children's development. The most powerful source of facilitating their inclusion is the human environment (12). By consequence, teachers-student with disability seems to be the key for a developing social behavioral skills of children (13, 14) meaning that the attitude of teachers regarding children with disability will assure a better support for adapted intervention programs.

The results of our study prove the fact that there is a significant difference in the characterization of those suffering from mental disability in that women have a more positive attitude than men. This may be due to the fact that women have more developed communication skills and better social empathy. Women are more willing to characterize a person with disabilities positively. Male subjects are not more pessimistic than women regarding the capacity for social integration, but have a more negative attitude than women when characterizing mentally disabled people.

Teachers working in primary education witness more spectacular developments in children during their first four years of primary school. Perhaps for this reason, results show that they have a deeper maternal attitude toward their pupils than teachers working in secondary education. Thus, the former is more prone to an optimistic approach regarding the development of mentally disabled people and to assessing them positively.

Young teachers show a higher level of optimism regarding the social insertion of mentally disabled people, an optimism also expressed by their positive characterization. On the other hand, older teachers are more reserved regarding social insertion and less generous with the positive characteristics used to portray the mentally disabled person.

Our research has also been aimed at emphasizing the differences between teachers with experience working with mentally disabled children and those without experience. The results have shown that young and less experienced teachers are more optimistic regarding integration; they use more positive characteristics and have a more favorable attitude toward mentally disabled

children. As with age-related differences, we consider that we have found here the cautious optimism of teachers who work or have worked with mentally disabled people. They know the problems the mentally disabled person really faces and are consequently more moderate both in their trust in the person's social insertion and in the person's characterization. We consider that the less favorable attitude which surprised us in experienced teachers may be explained by the fact that working with children with this type of disabilities is difficult, as they have a different behavior from a normal child - a behavior which causes problems in the classroom. The way to relate and communicate with these children is not at all easy and teachers must be trained to have skills from different areas: psychology, medicine, sociology, pedagogy (9).

CONCLUSIONS

Our research emphasizes that age, experience with mental disabled children and gender of teachers as independent variables are influencing the perception and the attitudes regarding people with disability.

Results are important for university curricula in order to train professionals working with mentally disabled people to have an objective opinion and to proper evaluate them.

VITAMIN D AND TISSULAR EXPRESSION OF VITAMIN D RECEPTOR IN OBESITY (Abstract): Vitamin D (VitD), a lipid-soluble hormone, is able to regulate the transcription of many genes through vitamin D receptor (vitD receptor - VDR). It has been shown that VitD deficiency is associated with obesity, characterized by a low degree inflammatory state, which contribute to the pathogeny of metabolic syndrome and type 2 diabetes mellitus. VitD deficiency is a public health problem, at the same time the global prevalence of obesity and cardiovascular diseases is continuously growing. Evidence from recent studies on animal models suggest that VitD or VDR deficiency promotes cardiomyocyte hypertrophy, which can be one of the mechanisms for increasing cardiovascular risk. The heart is one of the target organs of action for VitD, because VDR is expressed in cardiomyocytes. Also, previous in vitro studies have shown that VitD is able to inhibit the production of monocyte chemotactic factors (MCP-1) and other pro-inflammatory mediators in human preadipocytes and mature adipocytes. Inflammation is an important factor in the pathogenesis of atherosclerosis. In obesity there are not known data about correlations between plasma levels of VitD and VDR expression in the subcutaneous fat tissue, epicardial visceral adipose tissue, and in particular in myocardium. Also, there are still no studies to test VDR expression in myocardial cells and to investigate the results of dietary VitD supplementation on the expression of VDR in the epicardial adipose tissue and myocardium. **Keywords**: OBESITY, HEART, INFLAMMATION, VITAMIN D RECEPTOR.

VITAMIN D – MORE THAN A CALCIUM REGULATOR

It has been established in time the vital role of vitamin D (VitD) in the regulation of calcium and phosphate homeostasis, a key nutrient for maintaining the health of the musculoskeletal system (1). VitD deficiency is a public health problem. Humans obtain vitD either from exposure to sunlight or dietary intake, both whole food and supplementation (2).

The circulating form of Vit D is 25-hydroxycholecalciferol (25OHD) and the most active form is 1α,25-dihydroxyvitamin D (1α,25$(OH)_2$D) or calcitriol. The enzymes responsible for the activation to 1α,25(OH)2D are vitamin D-25-hydroxylase (25-OHase) and 25-

hydroxyvitamin D-1α-hydroxylase (1α-OHase or CYP27B1). Calcitriol is further degraded by 24-hydroxylase CYP24A1.

The worldwide prevalence of obesity has nearly doubled between 1980 and 2008. According to World Health Organization, in 2008, 10% of men and 14% of women in the world were obese (BMI ≥30 kg/m2), compared with 5% for men and 8% for women in 1980 , and the prevalence is rapidly increasing. As a group, obese individuals have decreased levels of circulating 25(OH)D, and, according to a recently published meta-analyses, are at a 35 % higher risk for vitD deficiency across all age ranges (1*).*While actually recommended daily dietary supplementation of vitD are at least 600 IU for healthy adults aged 19–70 (2), and 800 IU/d for those over 70 years old, these doses reflect adequate intake for maximal bone health and muscle function, but for obese populations may be necessary at least two to three times more vitD (1,3*).*

Recent experimental and human studies demonstrated an inverse correlation between adiposity and the level of VitD. VitD deficiency has been showed to be closely associated with obesity, which is a chronic, low-grade inflammatory state, and contribute to the pathogenesis of insulin resistance, metabolic syndrome, and type 2 diabetes mellitus (1*).*

VitD, a fat-soluble hormone, is able to regulate the transcription of many genes through vitD receptor (VDR) (4). The VDR functions in cells such as osteoblasts, skin keratinocytes, macrophages, and epithelial cells and modulates the action of 1,25-$(OH)_2D$, and in turn controls transcription of several genes (1*).* Adipose tissue is recognized as a target for VitD actions. In particular, adipocytes may be directly involved in the local synthesis and degradation of calcitriol, which is able to affect adipocyte biology by modulating preadipocyte differentiation, lipid accumulation and mobilization and also adipokine production (4). There are contradictory data in the literature regarding the expression of VDR in subcutaneous or visceral adipose tissues.

Muscle fat infiltration can be the result of aberrant trans differentiation of myogenic precursor cells into adipocytes, resulting in the formation of fat within the intermuscular space. Recent studies demonstrated that myogenic precursor cells have the potential to transdifferentiate towards the adipogenic lineage (5) and VitD has potent effects on both adipogenesis and myogenesis (6). Muscle fat infiltration has been shown to have a direct consequence on muscle strength and functionality, but it is also a key independent risk factor for metabolic diseases, such as insulin resistance, obesity and diabetes mellitus (3).

In rats, adipose tissue has been shown to sequester more vitamin D for significantly longer periods of time than other major tissues or organs. In humans, central adiposity in obese states is a key marker of metabolic syndrome, which, along with type 2 diabetes mellitus, has been identified to be associated with vitD deficiency. VitD deficiency may also be associated with lipid synthesis via action of the VDR. VitD and VDR also regulate de novo adipogenesis since VDR has been shown to be expressed in preadipocytes (1*).*

Recent studies reported that calcitriol induces genomic effects, leading to the synthesis of new proteins that affect muscle cell contractility, proliferation and differen-

tiation (7). Furthermore, mice lacking the vitamin D receptor showed a skeletal muscle phenotype with smaller and variable muscle fibers and persistence of immature muscle gene expression during adult life, suggesting a role of VitD in muscle development (8).

VitD deficiency can lead to myopathy, characterized by muscle hypotonia, weakness and atrophy of skeletal muscle. Muscle biopsies from VitD-deficient adults demonstrated enlarged interfibrillar spaces, fibrosis and loss of type II fiber complement (7). There was also found an increase in fat infiltration within the muscles (9), similar effects being observed in elderly individuals, where progressive loss in muscle mass and strength are seen at the onset of sarcopenia, associated with an increase in fat deposition within the tissue. Sarcopenia consists of a deterioration in muscles quantity and quality, a gradual slowing of movement, a decline in strength and power, and an increased risk of falls and fall-related injuries (10).

VITAMIN D, CARDIOVASCULAR SYSTEM AND INFLAMMATION

Cardiovascular diseases (CVD) are the most common causes of morbidity and remain the most important cause of death. Recent observational and prospective studies have shown an association between VitD deficiency and hypertension, diabetes mellitus, metabolic syndrome, coronary and peripheral arterial disease (PAD), and heart failure. Vit D has been shown to exert many biological activities, including reduction in blood pressure through down regulation of renine-angiotensin system (RAS), enhancement in insulin secretion and insulin sensitivity (11), protection against angiogenesis and regulation of cellular differentiation and proliferation through locally-formed calcitriol in tissues (12).

VitD deficiency has been also shown to impair endothelial function, which may be a supplementary contributing factor to increased CVD risk (1*)*. Recent studies suggested that serum 25(OH)D levels were inversely associated with coronary lesion severity established by coronary angiography, but not with arterial stiffness or peripheral arterial disease (12).

Epicardial adipose tissue (EAT) (epicardial fat) is a metabolically active visceral adipose tissue, which may locally interact with myocardium and coronary arteries through secretion of various adipokines and cytokines. Recent reports indicated that EAT accumulation may be a risk factor for coronary artery disease (CAD) and alterations in EAT biology, such as increased thickness, elevated inflammatory infiltrate and cytokine production, have been observed in CAD patients (6). The secretion of various epicardial inflammatory adipokines, including tumor necrosis factor alpha (TNF-α), interleukin-6 (IL-6), adiponectin, and monocyte chemoattractant protein-1 (MCP-1), contribute to an inflammatory milieu and play a significant role in the development and progression of atherosclerosis. Subjects with coronary artery disease (CAD) had elevated inflammatory infiltrates in EAT (13).

Evidence from studies on animal models suggest that vitD or vitD receptor (VDR) deficiency promotes cardiac hypertrophy, which might be also one of the mechanisms for increased cardiovascular risk (13). Thus, a recent experimental study revealed that vitD deficiency was associated with cardiomyocyte hypertrophy in

hypercholesterolemic miniswine and significantly decreased expression of VDR was found in ventricular cardiomyocytes of vitD-deficient swine (13). The heart is believed to be one of the target organ of vitD, because VDR is expressed in cardiomyocytes (14).

In addition to its well-known role as a regulator of calcium homeostasis and bone metabolism, vitamin D may exert other different functions. In particular, due to its ability to modulate T-lymphocyte proliferation and function, vitamin D exert immune-regulatory effects and suppress the production of inflammatory cytokines, thus being recognized as a potential anti-inflammatory molecule. Previous in vitro studies showed that vitD is able to down-regulate the expression of pro-inflammatory mediators in human monocytes stimulated with interferon and to inhibit the production of MCP-1 and other pro-inflammatory mediators in human preadipocytes and mature adipocytes (6).

In human adipose tissue, there are few studies which investigated the potential anti-inflammatory role of vitamin D. One study demonstrated that, as 25OHD level decreases, local EAT expression of both VDR and proinflammatory cytokines increases (13). In condition of plasma 25OHD deficiency, local vitamin D metabolism seemed to be suppressed and associated to an increased production of inflammatory mediators. It was also observed an increased expression of VDR associated to reduced plasma 25OHD level, as well as to increased EAT inflammation (15).

In conclusion, besides the vital role of vitamin D in maintaining the health of the musculoskeletal system, studies showed that VitD deficiency has been closely associated with obesity, induced an increase in fat infiltration within the muscles and cardiomyocyte hypertrophy, and significantly increased proinflammatory cytokines. It is not yet known which are the correlations between the plasmatic level of VitD and expression of VDR in subcutaneous adipose tissue, visceral epicardial adipose tissue and especially in myocardium in obesity. There are no studies which tested the expression of VDR in the myocardial cells and to investigate and correlate the results of diet supplementation with VitD on VDR expression in the visceral epicardial adipose tissue and myocardium.

THERMOPLASTIC MATERIALS APPLICATIONS IN RADIATION THERAPY (Abstract) This is an example of the use of thermoplastic materials in a high-tech medicine field, oncology radiation therapy, in order to produce the rigid masks for positioning and immobilization of the patient during simulation of the treatment procedure, the imaging verification of position and administration of the indicated radiation dose. Implementation of modern techniques of radiation therapy is possible only if provided with performant equipment (CT simulators, linear accelerators of high energy particles provided with multilamellar collimators and imaging verification systems) and accessories that increase the precision of the treatment (special supports for head-neck, thorax, pelvis, head-neck and thorax immobilization masks, compensating materials like bolus type material). The paper illustrates the main steps in modern radiation therapy service and argues the role of thermoplastics in reducing daily patient positioning errors during treatment. As part of quality assurance of irradiation procedure, using a rigid mask is mandatory when applying 3D conformal radiation therapy techniques, radiation therapy with intensity modulated radiation or rotational techninques.Key words: IMMOBILIZATION, THERMOPLASTIC MASKS, RADIOTHERAPHY.

This article presents one of the uses of thermoplastic materials in high-energy radiation treatment of malignant neoplasms, produced by linear particles accelerators (radiation).

Modern techniques of external radiation therapy allow high doses of X-rays or electrons in target tumor volumes defined after adapted localization and tumor extension criteria, reducing radiation doses to organs at risk in the immediate vicinity of the tumor.

These complex treatments involve accessories to immobilize the patient, high performance imaging methods: computer tomography (CT), magnetic resonance imaging (MRI), positron emission tomography (PET) for the precise localization of the tumor volume, algorithms that also include tissue inhomogeneities, high performance accelerators with multilamellar collimators, 3D conformal treatment, treatment with intensity modulated radiation therapy (IMRT), rotational therapy and imaging system for checking the treatment position of the patient [1].

MATERIAL AND METHOD:

Steps to follow in radiation therapy

1. CT Simulation. Carrying out an ac-

curate CT simulation by proper preparing and positioning the patient and through use of means of immobilization that allow further daily reproducibility of the position during the 5-7 weeks of treatment, is one of the most important steps for a proper treatment [2].

Depending on the anatomical region where the tumor that will be subjected to radiation is, the patient is comfortably positioned on a special support placed on the table of the simulator, afterwards the patient is immobilized in this position with the use of masks obtained by soaking for a few minutes (the time depends on the composition and thickness of the material) at 75^0C thermoplastic plates, of adequate size for the immobilized area. On the external surface of the formed mask are placed radiopaque markers corresponding to the cutaneous projection of the origin point for the CT scanning. After completion of the simulation, on the mask are noted patient identification and accelerator data that will be used for treatment and the mask will be handed to the assistent from the accelerator (fig. 1).

In case that during treatment the patient undergoes significant changes regarding the immobilized area (weight loss, reduction of initially voluminous adenopathy or local edema), leading to a looser mask or, conversely, to a tighter mask, the patient undergoes a process of resimulation and immobilized with a mask molded according the new aspect of the area of interest [3].

For preventing local changes in the pretreatment phase it is recommended that the time from the CT simulation to onset of treatment does not exceed two weeks.

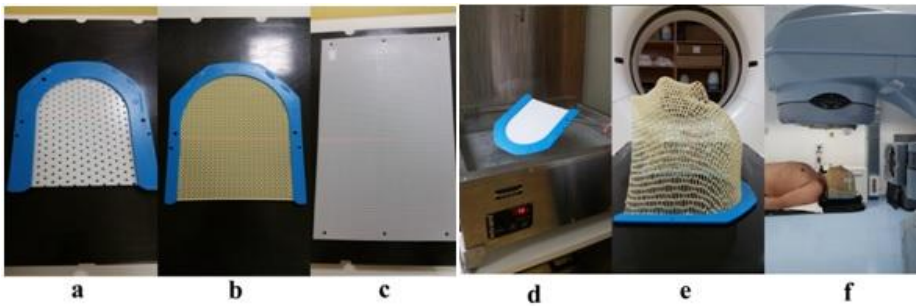

Fig. 1. Examples of the thermoplastic material prior to molding (1a, 1b, 1c), modeling in tank at 75^0C (1d) and after molding (1e, 1f).

2. The treatment plan. The developement of the treatment plan is based on shaping the target volumes and organs at risk on CT images obtained from simulation, followed by the prescription of the dose to the target volume and dose constraints for organs at risk.

The following volumes are identified: tumor macroscopic volume - GTV (gross tumor volume), the volume that estimates the microscopic extensions, the area of tumoral risk - CTV (clinical target volume) and target volume planned, which takes into account movement and positioning errors - PTV (planning target volume). The edges that are added to PTV depend on the irradiated zone, availability and quality of immobilizers used, the frequency of imaging verifications of the treatment position (daily, weekly), the average errors recorded in each radiation laboratory.

Completion of the treatment plan (fig.

2) involves the use of algorithms that simulate the effect of passing through of the beams of radiation through the target volume and generates the characteristic izodoses as well as dose-volume histograms [4].

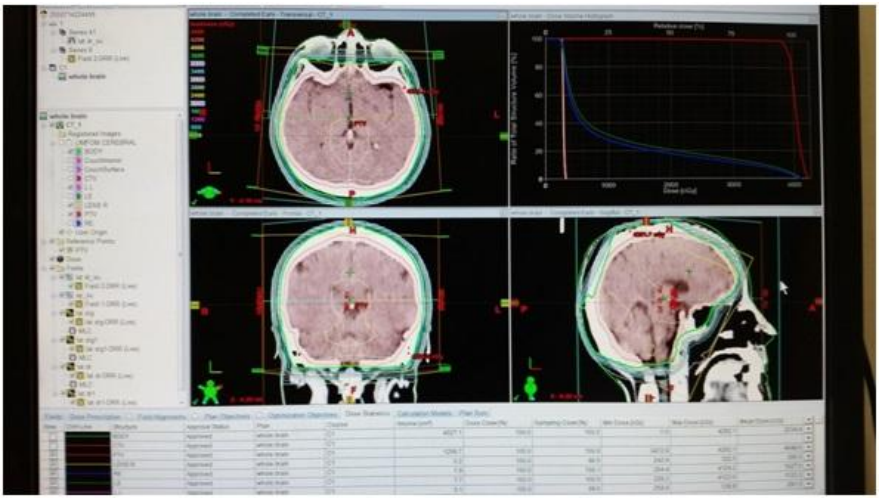

Fig. 2. The treatment plan for a patient with primitive brain lymphoma

3. Controls and implementation of treatment. The administration of high total radiation doses (50-70Gy) in tumor volume is done fractionated, with daily doses of 1,8-2Gy during 5-7 weeks, which involves repeating the verification procedures daily.

Positioning errors are verified through imaging by overlapping anatomic landmarks contoured in the images from the simulation with landmarks from the control images on the accelerator table (fig. 3) and are corrected before each treatment session [5].

Fig. 3. Imaging treatment position control, achieved at the accelerator

DISCUSSIONS

The use of thermoplastic masks for patients treated in the Radiation Laboratory of Regional Oncology Institute, Iasi has become a common practice, especially for irradiation of primitive or secondary brain tumors and also head and neck tumors. Availability of immobilization systems has reduced positioning errors (average errors 1-2mm corrected prior to administration of radiation dose) and enables advanced radiation techniques (IMRT, RapidArc).

CONCLUSIONS

This is a model of practice for accurate irradiation of tumor target volume, while protecting adjacent critical structures, which demonstrates the importance of patient immobilization for treatment reproducibility and safety, widely recognized and which continuesly raises concerns to optimize immobilizers [6].

α,β-DIBROMOCHALCONE DERIVATIVES – SYNTHESIS AND ANTIMICROBIAL ACTIVITY (Abstract): **Aim:** To obtain some chalcones and their dibrominated analogues and to evaluate their antimicrobial potential. **Material and methods:** Eight chalcones were synthesized using the Claisen-Schmidt condensation of acetophenone/4-bromoacetophenone and different benzaldehyde derivatives. These chalcones were further brominated using two different bromination agents: molecular bromine and pyridinium tribromide. The antimicrobial activity was tested using the disk diffusion method. **Results and discussions**: The classical bromination technique was compared to the eco-friendly one using pyridinium tribromide. Pyridinium tribromide bromination did not improve the reaction yields (except for one compound), but it had the advantage of being a stable, non-corrosive and non-toxic salt. The results of the antimicrobial assessment indicated that the bromination of the double bond slightly increased the antimicrobial potential in some cases, but the results obtained during the antimicrobial evaluation were modest, some of the derivatives being active especially on *Sarcina lutea* ATCC 9341 and *Bacillus cereus* ATCC 14579. **Conclusions:** In this study, eight chalcones and their dibrominated analogues were synthesized, four of the α,β-dibromochalcones being reported for the first time. Pyridinium tribromide was used as an alternative for liquid bromine, the main advantage of this method being related to the reduced toxicity of the reagents. The synthesized compounds did not exhibit a very good antimicrobial potential. **Keywords:** α,β-DIBROMOCHALCONE, BROMINATION, ANTIMICROBIAL.

Chalcones are an important class of compounds with a wide range of biological activities: antimicrobial, antiviral, antimalarial, antitubercular, anti-protozoal, cytotoxic, anti-inflammatory, immunosuppressive, antioxidant and analgesic (1, 2, 3). These substances, with relatively simple structures, which are generally synthesized by base catalyzed Claisen-Schmidt condensation of an aldehyde and the appropriate ketone in a polar solvent (ethanol), have a great synthetic potential, chalcones and

α,β-dibromochalcones being potential intermediates for the synthesis of various heterocyclic compounds (flavones, benzofurans, quinolones, pyrazoles, isoxazoles) (4, 5, 6). Different bromination agents can be used to obtain dibromochalcones: molecular bromine in different organic solvents, tetrabutylammonium tribromide, phenyltrimethylammonium bromine, boric acid with potassium bromide (7, 8). Due to the environmental issues caused by using molecular bromine and aggressive solvents in conventional bromination, there is a constant concern to develop new eco-friendly bromination techniques (8, 9, 10). One of these techniques involves the use of stable crystalline quaternary ammonium tribromides. Pyridinium tribromide ($PyrBr_3$) is an example of a stable, non-corrosive and non-toxic salt, easy to use for bromination under mild conditions. In solution, $PyrBr_3$ is in equilibrium with pyridinium bromide and Br_2, both acting as bromination agents (11).

The purpose of this study was to investigate the bromination of some chalcones using $PyrBr_3$, in comparison to standard bromination conditions.

MATERIAL AND METHODS

All the reagents and solvents employed were of the best quality available and were used without further purification. Melting points were determined using an electrothermal apparatus and were uncorrected. Elemental analyses were performed on an Elemental Exeter Analytical CE 440 Analyzer. The nuclear magnetic resonance (NMR) spectra were recorded on a Bruker Avance DRX 400 MHz Spectrometer (Bruker, Rheinstetten, Germany) equipped with a 5mm QNP (quadruple nucleus probe) direct detection probe and z-gradients. Spectra were recorded in deuterated chloroform ($CDCl_3$) at room temperature. The chemical shifts are reported as δ values (ppm) relative to the solvent residual peak (7.26 ppm for ^{1}H-NMR and 77.01 ppm for ^{13}C-NMR spectra). The atom labelling for the NMR assignments is that from fig. 1. The assignments of all the signals in the 1D NMR spectra were done using 2D NMR experiments such as H,H-COSY, H,C-HMQC and H,C-HMBC.

Chalcones synthesis – general procedure: Equimolecular quantities of acetophenone/4-bromo-acetophenone and the appropriate aromatic aldehyde were dissolved in ethanol 96° and cooled to 5-10°C in an ice bath. A solution of sodium hydroxide 15M was added dropwise and the mixture was stirred at room temperature for 90 minutes. The final products were purified by recrystallization from ethanol:water (1:1).

α,β-dibromochalcones – general procedures: Standard bromination with molecular bromine: A solution of bromine (5 mmoles) in chloroform was added dropwise while stirring over 5 mmoles chalcone previously dissolved/suspended in chloroform. The reaction was performed on an ice-bath. The bromination products were separated by filtration.

Bromination with pyridinium tribromide: 3 mmoles chalcone were dissolved in 6 ml acetic acid and 3.6 mmoles pyridinium tribromide were added. The mixture was heated under reflux for 30 minutes and, after cooling, the precipitate was filtrated.

The synthesis of the compounds is described in fig. 1:

2,3-dibromo-3-(3-bromofenil)-1-(4-bromofenil) propan-1-one (II_8) white crystals, m.p.= 150-152 ºC. Anal. calc. for $C_{15}H_{10}OBr_4$ (526): C 34.26, H 1.92, O 3.04; found: C 34.24, H 1.91, O 3.06. IR (KBr, cm^{-1}): 3029 (C-H arom.), 1683 (C=O), 575 (C-Br). ^{1}H-NMR ($CDCl_3$, 400.13 MHz, δ, ppm): 7.95 (d, J=8.8 Hz; 2H; $H_{2'}$, $H_{6'}$), 7.70 (d, J=8.4 Hz; 2H; $H_{3'}$,$H_{5'}$) 7.67 (s, 1H; H_9), 7.52 (d, J=8 Hz; 1H; H_7), 7.43 (d, J=7.6 Hz; 1H; H_5), 7.30 (t, J=7.8 Hz; 1H; H_6), 5.68 (d, J=11.2 Hz; 1H; H_2), 5.55 (d, J=11.6 Hz; 1H; H_3). ^{13}C-NMR ($CDCl_3$, 100.16 MHz, δ, ppm): 189.90 (C_1), 140.22 (C_4), 132.92 ($C_{1'}$), 132.48 (C_7), 132.43 ($C_{3'}$, $C_{5'}$), 131.32 (C_9), 130.36 (C_6), 130.34 ($C_{2'}$, $C_{6'}$), 129.77 ($C_{4'}$), 127.13 (C_5), 122.79 (C_8), 48.19 (C_3), 46.35 (C_2).

The antimicrobial activity of the compounds was evaluated using the disk diffusion method (12). Agar diffusion tests are often used as qualitative methods to determine whether bacteria are resistant, intermediately resistant or susceptible to different antimicrobial agents. Mueller Hinton (Oxoid) medium for bacteria and Sabouraud agar for fungal were used. The test microorganisms were *Staphylococcus aureus* ATCC

25923, *Sarcina lutea* ATCC 9341, *Bacillus cereus* ATCC 14579, *Bacillus subtilis*, *Escherichia coli* ATCC 25922 and *Candida albicans* ATCC 10231. The bacterial and fungal strains were incubated over night at 30 ^{0}C and suspensions were prepared from each microbial culture with the same density as the McFarland 0.5 turbidity standard. The suspensions of microorganisms were incorporated in the growth medium (melted and cooled afterwards at 50 ^{0}C) in a 1/10 ratio. After homogenization, 25 mL of this mixture were placed in Petri dishes (with a diameter of 9 cm). On the surface of each plate, after solidification, absorbent disks impregnated with 10 µL from the DMSO solutions (10 mg/mL) of the tested compounds were placed (the quantity of active substance/ disk = 100 µg). Positive control disks of Ampicillin 25 µg, Chloramphenicol 30 µg (for bacteria) and Nystatin 100 µg (for *Candida albicans*) were also used. After incubation (24 hrs at 37°C for bacteria and 48 hrs at 24°C for *Candida albicans*), the plates were observed (13).

RESULTS AND DISCUSSION

Eight chalcones and their dibrominated analogues were synthesized. Of the eight α,β-dibromochalcones, four had been previously reported – II_1, II_2, II_4 and II_7 (7, 8, 14). Due to the inconveniences caused by using liquid bromine in standard bromination, $PyrBr_3$ was used as an alternative. The main advantages of using $PyrBr_3$ were the reduced toxicity of the reagents and the fact that the brominating agent was gradually generated "in situ". $PyrBr_3$ is a solid substance and was easily manipulated in comparison with bromine – a corrosive liquid, capable of producing serious skin burns and of affecting the respiratory system. Standard bromination usually involves the use of chlorinated solvents (15), very aggressive for the environment and also suspected to have a carcinogen effect; $PyrBr_3$ bromination was performed in acetic acid, which was less toxic.

A comparison was made between the yields obtained by the two methods (fig. 2). Yields were not optimized. $PyrBr_3$ bromination did not improve the reaction yields (except for compound II_3), so the advantages of using $PyrBr_3$ were related to the safety of the executant and environment.

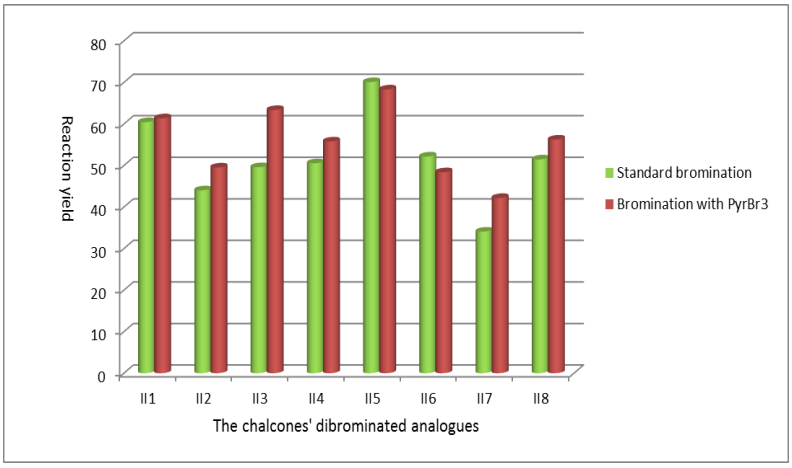

Fig. 2. Comparison of standard bromination and $PyrBr_3$ bromination yields

Antimicrobial screening: The presence of antibacterial or antifungal activity was indicated by the presence of an inhibition zone surrounding the absorbent disk impregnated with the tested compound. The zone of inhibition was measured and expressed in millimeters (tab. I).

The antimicrobial activity of the investigated substances was expressed in terms of the diameter of the inhibition zones: <9 mm – inactive; 9-12 mm - partially active; 13-18 mm - active and >18 mm - very active (16, 17).

Despite a great number of previous studies indicated a good antimicrobial activity for similar compounds (1, 2, 18), all the investigated chalcones (I_{1-8}) were inactive against all the tested bacterial and fungal strains (tab. I). Similar results have also been reported by other research teams (19). The bromination of the double bond moderately increased the antimicrobial potential in some cases (II_1, II_4, II_5, II_7), although it was previously observed that the antibacterial activity was due to the α,β-unsaturated carbonyl group, the hydrogenation of the double bond destroying the activity partially or completely (4). The α,β-unsaturated carbonyl group was considered a pharmacopeic group and the bactericidal effect of chalcones was related to the ability of the α,β-unsaturated ketone to undergo a conjugated addition to a nucleophilic group (ex. thiol) in an essential protein (1).

Sarcina lutea ATCC 9341 and *Bacillus cereus* ATCC 14579 were the most sensitive bacterial strains. Methoxy and chlorine radicals had a favorable influence, these results being in agreement with other studies (1, 20). Due to the modest results of the qualitative evaluation of antimicrobial activity, the quantitative determination (the minimum inhibitory (MIC) and minimum bactericidal (MBC) concentrations) was not justified.

CONCLUSIONS

In conclusion, we synthesized eight chalcones and their dibrominated analogues, four of the α,β-dibromochalcones being reported for the first time. The compounds were characterized by elemental and spectral analysis. In the context of finding eco-friendly synthesis techniques, we used pyridinium tribromide as an alternative for liquid bromine. The main advantage of this method was the reduced toxicity of the reagents. The synthesized compounds did not exhibit a very good antimicrobial potential, some of the derivatives being active especially on *Sarcina lutea* ATCC 9341 and *Bacillus cereus* ATCC 14579.

NEWS

ANTI-INFLAMMATORY EFFECT OF *STAPHYLOCOCCUS AUREUS* ON AIRWAY EPITHELIAL CELLS

A study by Chekabab *et al* examined the way bacterial cells modulate inflammatory responses in the setting of polymicrobial infections. Two major respiratory pathogens, *Pseudomonas aeruginosa* and *Staphylococcus aureus* can simultaneously colonize the airways of patients with chronic obstructive diseases (e.g. cystic fibrosis). The mechanism by which airway epithelial cells integrate bacterial stimuli in the case of polymicrobial colonization or infection is unknown. Since epithelial cell signaling is crucial for the activation of innate immune responses, the study examined the inflammatory responses to *P. aeruginosa* and *S. aureus* co-stimulations. Immortalized airway epithelial cells exposed to bacteria-free filtrates from *P. aeruginosa* induced a high synthesis of IL-8, while bacteria-free filtrates from *S. aureus* showed a minimal effect. However, in the case of co-stimulation with bacteria-free filtrates from *P. aeruginosa* and *S. aureus*, *S. aureus* filtrates inhibited IL-8 production induced by *P. aeruginosa*, showing potent anti-inflammatory effects. It also decreased IL-8 production induced by the TLR1/TLR2 ligand Pam3CysSK4 and dampened TLR1/TLR2-mediated activation of the NF-κB pathway. These results demonstrate that *S. aureus* modulates inflammatory responses in the setting of polymicrobial infections (Chekabab SM, Silverman RJ, Lafayette SL, Luo Y, Rousseau S, Nguyen D. *Staphylococcus aureus* Inhibits IL-8 Responses Induced by *Pseudomonas aeruginosa* in Airway Epithelial Cells. *PLoS One*. 2015;10(9):e0137753. doi: 10.1371/journal.pone.0137753. eCollection 2015).

COLORECTAL CANCER - EPIDEMIOLOGICAL PERSPECTIVES IN THE ONCOGENETIC CONTEXT (Abstract): The neoplastic pathology is one of the challenges of modern medicine, both in terms of epidemiology (morbidity, mortality and risk factors), as well as in terms of prevention, diagnosis or treatment. The progress of knowledge regarding risk factors and the identification of new diagnosis or therapy methods in the management of patients with colorectal cancer have led to a series of approach changes which create new perspectives not only for those affected by the disease, but also for their families. Risk factors for CRC include: modifiable factors (endogenous and exogenous factors) and non-modifiable factors (genetic factors). The risk of an individual belonging to the general population to develop CRC at a certain point in life is of 5%, while the risk of a subject with Lynch syndrome may reach 70-80%. The genes which potentially increase the risk of CRC include: MMR, MLH1, MSH2, MSH6 (high-penetrance genes) and APC, BRAF, CTNNB1 / beta-catenin, FBXW7, KRAS, PIK3CA, SRC and P53 (low-penetrance genes). The most used methods of screening for the general population are: the HEMOCCULT test, the colonoscopy and the flexible sigmoidoscopy, while for the groups at risk (with one or more risk factors) these include: the oncogenetic investigation (including the assessment of family history of familial adenomatous polyposis (or FAP), attenuated FAP (AFAP), hereditary non-polyposis CRC (HNPCC), personal history of colorectal cancer or adenoma, chronic ulcerative colitis and Crohn's disease and molecular testing of individuals with risk factors). **Keywords**: COLORECTAL CANCER, EPIDEMIOLOGY, INCIDENCE, SURVIVAL, RISK FACTORS.

Neoplastic pathology is one of the challenges of modern medicine, both in terms of epidemiology (morbidity, mortality and risk factors), and in terms of prevention, diagnosis or treatment. The estimated incidence per year has an upward trend from 10 million new cases in 2000 to 15 million in 2020 (1), cancer mortality being ranked 2nd after cardiovascular diseases.

Colorectal cancer (CRC) is a real public health issue both in Romania and worldwide, which is accounted for by the mor-

bidity and mortality recorded. The evolution of progress regarding the knowledge related to risk factors and the identification of new diagnosis or therapy methods in the management of patients with colorectal cancer have led to a series of approach changes which create new perspectives not only for those affected by the disease, but also for their families (2, 3).

CRC is the third oncological pathology in the world in terms of incidence (with approximately 1-2 million new cases each year); it is the second pathology in terms of prevalence and the fourth cause of death in the world (with 600,000 deaths annually) (4). At a worldwide level, there is a wide variation in incidence, but the geographical pattern is similar for women and men. Colorectal neoplasia is the 3rd most common cancer type in men (10% of all cancers) and the 2nd most common cancer in women (9.2% of the total), 55% of cases being identified in more developed geographical areas. Regarding the global mortality rate, the variability is low, with the highest percentage recorded in Central and Eastern Europe (20.3 deaths / 100,000 men and 11.7 deaths / 100,000 women). Most deaths (52%) were recorded in less developed countries, where the survival rate is lower. In Romania, there is also an upward trend in the CRC incidence in both sexes – the male / female ratio is of 1/3 and is rapidly growing; for every 10 years of life after the age of 45 the numbers double (4).

RISK FACTORS

CRC risk factors include: age (over 40% of cases involve patients aged over 75); gender (more common in men); diet (high in red meat or processed meat and animal fats); obesity and overweight; alcohol consumption; smoking; occupational exposure to carcinogens (asbestos); ionizing radiation; presence of infection history; various medical conditions (adenomatous polyps, inflammatory bowel disease-Crohn's disease, ulcerative hemorrhagic rectocolitis, biliary lithiasis, diabetes, metabolic syndrome); personal history of cancer (colorectal, oesophageal, laryngeal, lung, prostate, endometrial and breast cancer, as well as chronic lymphocytic leukaemia or melanoma); family history and genetic syndromes (familial adenomatous polyposis; hereditary nonpolyposis colorectal cancer; BRCA1 mutations) (5). Risk factors for cancer are multiple, presenting a low positive predictive value, except hereditary risk factors. Genetic predisposition for the development of malignancies due to genetic modifications is 70-80%, which is the only risk factor that reaches the positive predictive value, justifying medical and oncogenetic monitoring.

The risk of an individual belonging to the general population to develop CRC at a certain point in life is 1 out of 20 (5%), while the risk of a subject with Lynch syndrome may reach 70-80% (6).

Hereditary CRCs are classified into two main groups: polyposis forms, which include *Familial Adenomatous Polyposis* (FAP), *attenuated FAP* (a subtype of FAP in which the subject has less than 100 polyps and colorectal cancer that occurs at a young age), *Gardner syndrome* (a subtype of FAP which is accompanied by benign tumors of the skin, soft tissue and bones) and nonpolyposis forms, comprising: *Lynch syndrome* (LS) / *hereditary nonpolyposis CRC* (Hereditary Nonpoly-posis Colon Cancer) (HNPCC), *Turcot Syndrome* or *Peutz-Jeghers Syndrome* (7, 8).

The genes that modify the risk of CRC include: genes with major contribution

(high-penetrance genes): MMR, MLH1, MSH2, MSH6 and genes with variable contribution (low-penetrance genes), for which the most common somatic mutations of CRC described by Roy and Majumdar in 2012 appeared with genes such as APC, BRAF, CTNNB1 / beta-catenin, FBXW7, KRAS, PIK3CA, SRC and P53 (9). Genetic instability (10) in hereditary CRC is due to germinal mutations in the APC gene for cases diagnosed with FAP / attenuated FAP (9) and to DNA repair gene mutations (MMR) for cases of Lynch Syndrome (LS) (11, 12). This genetic instability in the case of FAP has its origins in the germ-line mutations of the APC gene on chromosome 5q21-22, but it may also exist in the MYH gene. Lynch syndrome is caused by mutations in DNA repair genes, namely *MLH1, MSH2, MSH6, PMS2* (13). Among these, *MLH1 and MSH2* genes, which cause a high level of instability, are responsible for the appearance of more than 90% of the cases of LS (14), in contrast to the 10% of cases attributed to mutations in the MSH6 gene, which causes a partial deficiency of MMR functions (13). The presence of hereditary mutations in *MLH1 vs. MSH2* is associated with an increased risk of developing extra-colonic malignancies (15, 16).

SCREENING (EARLY DETECTION)

Screening methods for the early detection of colorectal cancer, evaluated by numerous studies, include tests for the detection of occult blood in the feces, colonoscopy, flexible sigmoidoscopy and double contrast iriography. Recently, some modern and non-invasive methods have been introduced – virtual colonoscopy and genetic testing of feces for neoplastic DNA (17).

Currently, there are different types of faecal occult blood tests: *Faecal Occult Blood Testing (FOBT)*, *Hemoccult SENSA* (a guaiac test, but more sensitive) *Heme-Select* (a test to detect human hemoglobin by immunochemical methods) or *Hemo-Quant* (for quantitative detection of faecal occult blood by means of fluorescent light) (18), but the most used is the *Hemoccult test*, which involves the detection of fecal occult blood by using an indicator substance (guaiac) impregnated on a piece of paper. The test is not specific to CRC, as there are also other non-cancerous lesions that may be tested by using this method. False positive results (about 2-6%) may occur in case of colorectal polyps, diverticulitis or anorectal lesions (hemorrhoids, fissures, rectitis). A big disadvantage of the *Hemoccult test* is represented by the false negative results (40% of cases), which may be due to: the presence of vitamin C in the diet, failure to follow a high-residue diet, use of expired tests, degradation of hemoglobin by bacteria in the colon or a cancerous lesion that is not bleeding when the faeces sample is collected. Other disadvantages include: the need to collect 3-6 faeces samples (due to the intermittent bleeding) and the high specificity only for the lesions of the left colon. In its non-hydrated form, the *Hemoccult test* has a sensitivity of 72-78% and specificity of 98%; after rehydration, the sensitivity of the test increases to 88-92%, but the specificity drops to 90-92% (17, 19). Another test used in the detection of feces occult blood is the *Fecal Immune Test* (FIT), which, although it has proved to be a more reliable screening method as it is based on a "Ag-Ab" reaction, does not replace the common use of the *Hemoccult test* because it is more expensive (20).

A modern approach to the early detection of CRC involves the use of DNA

markers, RNA and protein as diagnosis strategy (*Faecal DNA* and *RNA Test*). These molecular tests are non-invasive and are based on the fact that the neoplastic cells (CRC) have a high mitotic index and a low adhesion to the basal membrane, which facilitates their ***continuous*** exfoliation into the lumen of the colon (as opposed to the ***intermittent*** loss of blood detected by FOBT) used for molecular analysis (17).

Colonoscopy is considered a method of maximum accuracy for the diagnosis of CRC and of colorectal polyps ("golden standard"), which allows multiple and targeted biopsy of lesions detected in the lumen of the colon as well as polyp resection. The literature shows that colonoscopy can allow visualization of the *caecum* in 98.6% of cases. The sensitivity of the method is of 96.7% for the detection of cancerous lesions of and of 85% for the detection of large polyps, but it falls to 78.5% for the diagnosis of polyps sized <5 mm; its specificity is of 98% (21).

Following the results of numerous epidemiological studies which support the idea that the risk of developing colorectal cancer decreases when precancerous lesions are removed (adenomatous polyps), *flexible sigmoidoscopy (FS)* was recommended to be used as a screening method. Sigmoidoscopy has the advantage that, in comparison with colonoscopy, it requires less preparation time and is usually performed without sedation, but has the great disadvantage that it only detects distal colon cancers. *FS* (of 60 cm) has replaced rigid rectosigmoidoscopy because it can help to explore a larger segment of the colon and is better tolerated by patients. Compared to the *Hemoccult test*, FS has the advantage that it can help to directly visualize the colon or to identify and take targeted biopsy samples from the detected lesions (17).

Although *computed tomographic colonography* (CT colonography or CTC) or *virtual colonoscopy* is better accepted by the investigated subject compared to colonoscopy, in the case of symptomatic patients it is still little explored for screening (22). Sedation is not required for this technique, yet preparation is necessary in conventional colonoscopy. Meta-analysis studies reveal that sensitivity and specificity in CT colonography are high for identification of polyps > 10 mm (82%), but not for smaller polyps (56% for polyps <5 mm and 63% for lesions between 6 and 10 mm) (17). Although its use as a first option for CRC screening is unclear, the American Gastroenterological Association recommends CT colonography every five years (21).

Other Exploratory Techniques. There are many new endoscopic techniques (wide-angle colonoscopy, capsule endoscopy, narrow band imaging, auto-fluorescence imaging system, etc.) that are still in the evaluation stage but appear to be promising for CRC screening, as they will help to increase the CRC rate detection, especially for proximal colon and they will improve the population acceptability (17). The effectiveness of these methods will be evaluated after a period of time of use (23, 24).

The logical approach in the management of the case of hereditary CRC where a mutation of the genes involved in increasing the risk for cancer (MMR, APC) was identified, early detection of subjects at high risk of developing this neoplasia (*oncogenetic screening*) and adequate monitoring through personalized oncogenetic supervision of these subjects, of patients operated for colorectal cancer, and of their families represent a modern approach to be

included in current strategies for colorectal cancer prevention.

The consequence of detecting a mutation is the placement of the patient under oncological supervision and the application of primary, secondary or tertiary prevention measures such as: adaptation / modification of medical or surgical therapeutic measures, differentiated use of screening and early diagnosis measures (onset at younger age, high frequency, special tests) or individualized application of preventive measures: removal of polyps, etc. (25, 26). Subjects who present mutations in the APC gene are monitored regularly by repeating the colonoscopy every 2-3 years since adolescence. The frequency of testing is adjusted according to the number, size and character of the polyps. Besides monitoring, risk reduction strategies such as colectomy or procto-colectomy can be proposed given that the risk of cancer onset reaches 100% at the age of 50 and that the peak incidence of occurrence is during the 3rd decade of life (26).

CONCLUSIONS

A review of risk factors, of main early detection methods and of other methods of prevention for colorectal cancer reveals the evolution recorded in the management of patients with this pathology. The main risk factors include: age; gender (more common in men); diet (high in red meat or processed meat and animal fats); obesity and overweight; alcohol consumption; smoking; occupational exposure to carcinogens (asbestos); ionizing radiation; presence of infection history; various medical conditions (adenomatous polyps, inflammatory bowel disease – Crohn's disease, ulcerative hemorrhagic rectocolitis, biliary lithiasis, diabetes, metabolic syndrome); personal history of cancer (colorectal, esophageal, laryngeal, lung, prostate, endometrial and breast cancer, as well as chronic lymphocytic leukemia or melanoma); family history and genetic syndromes (familial adenomatous polyposis, hereditary nonpolyposis colorectal cancer; BRCA1 mutations). The most used methods of screening for the general population are: test HEMOCCULT, colonoscopy and flexible sigmoidoscopy, while the risk groups (with one or more risk factors) these include: the oncogenetic investigation (including the assessment of family history of familial adenomatous polyposis (or FAP), attenuated FAP (AFAP), hereditary nonpolyposis CRC (HNPCC), personal history of colorectal cancer or adenoma, chronic ulcerative colitis and Crohn's disease and molecular testing of individuals with risk factors). Among the preventive measures, genetic screening in high-risk groups and individualized oncogenetic monitoring stand out as modern approaches. Oncogenetics will have an essential contribution in the early detection of hereditary risk cases as well as in the effective management of patients diagnosed with this condition, which, given the epidemiological evolution of the phenomenon, has proved to be one of the major public health issues at present and in the near future.

NEWS

HORMONAL CONTRACEPTIVES, GENITAL TRACT INFECTIONS AND HIV RISK

The hormonal contraceptives and genital tract infections are associated with altered cervical immunity. A recent study that evaluated changes in cervical immunity after taking hormonal contraceptives showed that the women who used injectable depot medroxyprogesterone acetate and those who use estrogen-progesterone oral contraceptives had increased levels of proteins that attract HIV host cells. Also, the effect of hormonal contraceptives was exacerbated in presence of disturbed vaginal microbiota or genital tract infections such as gonorrhea, chlamydia, genital herpes, trichomoniasis and candidiasis. The levels and the type of immune mediators, infection status and hormonal contraceptives increase HIV risk by their cumulative action (Fichorova RN, Chen P-L, Morrison CS, Doncel GF, Mendonca K, Kwok C, Chipato T, Salata R, Mauck C. 2015. The contribution of cervicovaginal infections to the immunomodulatory effects of hormonal contraception. mBio 6(5):e00221-15. doi:10.1128/mBio.00221-15).

ELECTRONIC CIGARETTE–A WAY OF SMOKING CESSATION? (Abstract): Specialists have the ethical obligation to promote smoking cessation using evidence-based therapeutic strategies. In the context of the growing popularity of the electronic cigarettes (ECs), the smokers asking us about it and we must be ready to provide expert advice. With the evidence available to date we must be cautious in recommending of the smokers to use ECs for smoking cessation because these have not proven superiority over drugs used for smoking cessation approved by the Food and Drug Administration (FDA), ECs are not FDA approved, short-term safety data shows that they cause airway reactivity and health risk of exposure to ECs in the long term is unknown. Before the ECs to occupy a place in the standard clinical approaches for the treatment of tobacco addiction longer needed more data about their safety clinical and regulatory of their use. **Keywords:** ELECTRONIC CIGARETTE, SMOKING CESSATION, EXPERT ADVICE.

Complete tobacco cessation is the best outcome for smokers. Electronic cigarettes (ECs) are the newest and most promising products for Tobacco Harm Reduction (THR) (1). ECs are electrically-devices: a lithium battery, attached to a heating element (atomizer) that vaporizes a humectant (propylene glycol, glycerol, distilled water, vegetable glycerin and/or polyethylene glycol), flavorings and liquid nicotine. Consumers (namely " vapors") may choose from several nicotine strengths, non-nicotine liquids, and a more than 7500 unique flavors of e-juice were available in January 2014 (2); this selection is a characteristic feature of ECs from any other THR products. Since they appeared in 2003, there has been constant development of more efficient and appealing ECs (2).

E-cigarettes are attractive because they provide behavioral aspects of smoking (hand-to-mouth movement, vapor that simulates tobacco smoke, flavorings that simulate cigarette taste), address to the sensory stimulation (3), psychopharmacologic (i.e., nicotine) (4) and social aspects. A range of reasons are reported for using ECs, mainly to quit or reduce smoking, to use a product

apparently healthier than tobacco, to overcome smoking restrictions, and to reduce costs related to tobacco dependence (5). All of this explains why ECs is believe to be effective in reducing tobacco smoking (6, 7) and are efficient as long-term substitutes of traditional cigarettes (3).

The use of ECs is apparently booming. It is estimated that in 2014 there were 466 brands (2). Sales are forecasted to increase by a factor of 17 by 2030 (8). Data from the United States, United Kingdom, Canada and Australia suggest that more than three-quarters of current and former smokers consider ECs less harmful than traditional tobacco. In the same study ECs use is higher among non-daily smokers and heavier smokers than among daily-smokers and smokers of fewer cigarettes (9). The number of nonsmoking youth that use ECs is rising and associated with increased intentions to smoke cigarettes (10). Adolescent ECs use it seems to be related much more with adolescent sensation seeking (11), rather to tobacco reduction or cessation behavior. It should be emphasized that this increase in ECs use has emerged despite the concerns raised by public health authorities about the safety and appropriateness of using them as alternatives to smoking (12, 13).

We can divide the studies targeted on safety/risk profile of ECs use into chemical, toxicological and clinical studies (14).

Clinical studies are the most informative, but the relatively recent entry of ECs into the market and the lengthy lag time for onset of many diseases of interest (i.e. cancer), conclusive evidence about the association of ECs use with such diseases will not be available for years or even decades. Accordingly, most research is now focused on in vitro effects, with clinical studies limited into evaluation of short-term use or pathophysiological mechanisms of smoking-related diseases (14, 15, 16). At present, ECs are highly variable (differing design, materials, utilization, combustion voltage, and liquid cartridge concentration), because the manufacturing and distribution of these products, and also cartridge manufacturing and production is unregulated. This is another barrier to effectively studying the potential adverse and beneficial effects of ECs (17) and adding to the complexity of trying to counsel patients regarding their safety (16).

Chemical studies have two mainly problems: one is fails to address unknown, potentially toxic contaminants because usually focused on the known specific chemicals (investigated concentrations of several substances known to be toxic/carcinogenic in conventional cigarette) (18), and the other one arise from unknown effects when these substances are heated and inhaled, although these chemicals in flavors are approved for use in the food industry (14, 18). Thus makes difficult to appreciate in vivo effects of such substances. Therefore, we would be cautious in conclusions, because this kind of studies does not offered any objective information about effects of use of these substances (14). Many studies found that the product labels did not show the concentrations of solvents and flavorings (18). Much more, some studies showed that nicotine-free products were found to contain nicotine, sometimes in high concentrations (20, 21). In a recent study (22), cancers causing agents, formaldehyde and other toxicants like acrolein have been found into some ECs brands to

be as high as in the smoke produced by some cigarettes.

At present, there are only few **toxicological studies**, mostly on established cell lines and approach of cytotoxic effects has its deficiency. Patterns of ECs toxicity may fluctuate due to design features in the device, type and source of ingredients, and the manufacturing (including quality control measures) (19). Again, we cannot directly applied the results in vivo situation (14, 19), because a range of results is to be expected from different or the same cell lines and exists the risk of over or under estimating the toxic effects interpretation (23, 24, 25, 26). For example, in a recent study (26), it was found that at least four of their samples were not refills but concentrated flavors. It must be note that, the levels of cinnamaldehyde found to be cytotoxic were about 400 times lower than those currently approved for use (27). Another study of the ECs use cytotoxicity on embryonic and adult cells showed a decreased cellular survival due to the flavoring agents (23), so that maybe these flavors, not the nicotine, are the potentially harmful ingredients in e-juice. It should be done studies that comparing the potential cytotoxicity effects of ECs vapor with those resulting from the exposure of tobacco smoke should be mandatory, but unfortunately standards for vapor production and exposure protocols have not been clearly defined (14).

Data from clinical trial have found no significant differences in adverse events between ECs use and nicotine patches (6). Supporting this, other clinical studies have announced clinically minor adverse events with ECs use (mouth irritation, cough, and nausea) (28) or lower rates of adverse events than tobacco use (7). On the other hand, the Food and Drug Administration (FDA) has received reports related to the ECs use associated of both minor adverse events (headache, chest pain, nausea, cough) and major adverse events (hospitalizations for pneumonia, congestive heart failure, seizure, rapid heart rate, and burns related to routine use) (29). It must be note that, the longest duration of a clinical trial has been 24 months (30). Accordingly, these clinical studies evaluated the adverse effects of short-term EC use. Despite on evidences from these clinical trials of harmful effects of vamping (cardiovascular and respiratory functional outcomes), these are considered milder compared with smoking traditional cigarettes. It is required data from longer-term clinical studies before any clearly conclusions are made because it is difficult to assess the prognostic implications from few and short existing studies (14, 19).

Regarding chemical, toxicological and clinical studies, a recent review about ECs use health effects (18) appreciated that many studies found harmful substances: fine/ultrafine particles, cytotoxicity, metals, carcinogenic tobacco-specific nitrosamines and carbonyls, some in most samples, others in few, some in high concentration, as high as in conventional cigarettes or higher, but mostly slow or trace levels. In November 2014, the FDA reported that has detected levels of carcinogens and toxins, such as diethylene glycol (a harmful ingredient found in antifreeze) in laboratory analyses of 18 flavors and different cartridge types of ECs (31).

CONCLUSIONS

At present, on the base of studies per-

formed until now (many methodological problems, few and small studies, inconsistencies and contradictions in results, lack of long-term results), no definite conclusions can be established on the safety of ECs use (16, 18, 19).

It must be note that ECs use can also have adverse health effects on non-users (16). During pregnancy due to the perception that ECs are safer than traditional tobacco, may increase their use (32). A toxically study revealed the cytotoxic effects associated with ECs flavoring agents on embryonic cells and this could leading to embryonic loss or developmental defects (23). The risks associated with embryonic exposure to the chemical constituents in ECs in not completely understood. E-cigarettes may be a potential source of third hand exposure to nicotine (33). As ECs use has proliferated, the number of calls to poison centers involving unintentional exposure to ECs and e-juice, ingestion, inhalation, or skin absorption by young children, has markedly increased (34). Importantly, the lethal dose of nicotine to a previously unexposed person is around 0.5 to 1 g (35), and bottles of nicotine solution can be obtained via Internet (home mixing) (16). Some lithium batteries are poorly designed (low-quality materials, manufacturing defects) and improper use can causes fires or explosions (in house, in car, skin burns) (36).

ECs are nicotine-delivery products. As a consequence, the ECs users will always risk associated with nicotine use – the potential disease and related side effects (increased blood pressure, heart rate, micro vascular injury and dependence) (17). All medically approved treatments for smoking, have concentrated on total abstinence from nicotine (37). It must be note that, almost all the health risks come from various substances (tar, chemicals) found in the smoke, not from nicotine (38). Nicotine is considered as harmless by some health professionals, but others do not agree this point of view (39). The existing evidence shows that ECs aerosol is not just "water vapour" as is often claimed in the marketing for these products (15). Much more, ECs use represented serious threats to adolescents (10, 11) and fetuses (23). Additionally, it increases exposure of non-smokers to nicotine and a number of toxicants (15, 16, 33, 35).

Despite the fact that direct claims about cessation efficacy are prohibited by law, the ECs manufacturers make indirect claims about cessation, through product user testimonials (16). For many years ECs have been used as a healthier alternative to smoking or as an aid to smoking cessation (40, 41, 42, 43). The only existing randomized smoking cessation study has showed that ECs were not significantly more effective than nicotine patch therapy (6). Some prospective studies were very promising about ECs' effect as a smoking or as an aid to cut down or quit (7, 44) and a recent 'real-life' study showed that ECs increased cessation rates more than no aid/nicotine replacement treatment (45). A meta-analysis found that ECs users were significantly less likely than non-users to have cessation smoking (46) and a study in cancer patients showed that EC-users were twice as likely to be smoking at the time of follow-up as non-users (47, 48).

Specialists have the ethical obligation to promote smoking cessation using evidence-based therapeutic strategies. In the context of the growing popularity of the ECs, the

smokers asking us about it and we must be ready to provide expert advice. With the evidence available to date we must be cautious in recommending of the smokers to use ECs for smoking cessation because these have not proven superiority over drugs used for smoking cessation approved by the FDA, ECs are not FDA approved, short-term safety data shows that they cause airway reactivity and health risk of exposure to e-cigarettes in the long term is unknown. Before the ECs to occupy a place in the standard clinical approaches for the treatment of tobacco addiction longer needed more data about their safety clinical and regulatory of their use.

FROM PUNISHMENT TO EDUCATION – JUVENILE DELINQUENCY IN ROMANIAN CRIMINAL LAW (Abstract): For centuries children were considered "mini-adults". Together with expressing the need to educate children and putting a stop to their integration in the work field from the earliest years the 19th century also displayed a new image of the child, which clearly separates him from the adults. In this paper the authors analyze the Romanian legislation addressing juvenile delinquency in criminal temporal evolution. On the one hand the minority age limits are sought and modulation of legislative provisions according to these, and on the other hand, types of penalties for minors are discussed. The authors conclude that the approach to juvenile delinquency in the current Romanian Criminal Code is the result of a long process of reflection of the legislators on adopting a different system of sanctions for juvenile offenders and on creating special regulations concerning the prosecution, trial and enforcement of the decisions regarding them. **Keywords:** MINORITY, DELINQUENCY, ROMANIAN CRIMINAL LAW.

A minor is a person before their coming of age, set at 18 in most countries, which legally confines the child's status of adulthood.

For centuries children were considered "mini-adults". Together with expressing the need to educate children and putting a stop to their integration in the work field from the earliest years the 19th century also displayed a new image of the child, which clearly separates him from the adult.

The idea of juvenile crime emerged in history from a sociological perspective, first being developed conceptually in the 19th century in Great Britain, and became a well defined social phenomenon, with clear outline of specific criminal behavior in children (1).

Nowadays it is recognized that juvenile delinquency is a multi-factorial phenomenon that is imposed on a particular, fully evolving and changing, psychosomatic field. From a sociological perspective, the juvenile antisocial behavior may represent a normal part of growing up but it can also be a warning sign that predicts a pattern of criminal behavior, persistently evolving over time.

In the developing of the underage person, childhood is succeeded by adoles-

cence, with no clear chronological boundaries in between though. As a statistically-based convention, adolescence includes the age of puberty, ranging between 11 and 12 years old and 14 and 15 years old and adolescence itself, until the age of 18. By the age of 18 all the psycho-physiological and biological processes are produced, as well as the events that mark the transition to adulthood.

During adolescence there is acceleration of both the physical development from a somatic and morphological point of view and of the changes in social and psycho-emotional sphere. These changes are produced in an uneven manner, with individual variations that create new models of proper functioning.

The process of moral development, whose disturbances are directly involved in the dynamics of juvenile delinquency, was dividing into three levels, starting with preconvention and going through convention, in order to reach the post-conventional level. At a preconvention level, specific to children under 9 and to some teenagers, social norms are external to the self, so the individual appears to not understand or support the rules of society. The conventional level is characteristic to most teenagers and it is aimed at rational individuals that integrate social norms and act to achieve acceptance and admiration of others. The post-conventional level is reserved to a small number of individuals who distinguish the "Self" from the social rules and define their values in terms of principles (2).

Antisocial acts committed by juveniles show the outline of a model of deviant behavior compared to the accepted model within society. The deviant model is actually an expression of personality structures organized in disharmony, with predominance of certain traits such as aggressiveness as a form of reactivity, intolerance to frustration, social and emotional immaturity. Due to such features, the minor cannot adapt to social life and he deviates from the accepted social norms, which may lead to a situation where he might commit antisocial acts (3).

Age and psycho-physical characteristics of minors justify a social response to antisocial acts committed by them, different from that adopted in the case of adult offenders, starting from the conditions of the judicial process and all the way to the sanctions (4). Also, the minimum age of criminal responsibility under which minors cannot be held liable for offenses should be set according to their level of emotional, mental and intellectual maturity (4, 5).

Minority is a period of formation and completing the profile of one's personality and psychosocial maturation, which means that exterior rehabilitation interventions are justified and effective. They are intended to restructure and rebalance personality by reorganizing its components in order to establish a connection between the behavior model of the minor and that accepted by society and to prevent reiteration of antisocial acts (3).

Imprisonment of juvenile offenders should be an extreme measure, the place of detention of minors being separated from that of adults (4, 6, 7). The application of alternative measures to imprisonment, which allows juveniles to maintain positive connection with their family, school and community and increase their chances of re-socialization, is important if we were to consider a decrease of recidivism, as the increased risk of recidivism of juveniles detained is well known.

In this paper the authors analyze the Romanian legislation addressing juvenile delinquency in criminal temporal evolution. On the one hand the minority age limits are sought and modulation of legislative provisions according to these, and on the other hand, types of penalties for minors are sought.

MINORITY IN ROMANIAN CRIMINAL LAW

Age was always a criterion for customization and reduction of sentences in Romanian legislation since the Middle Ages, when the first legal regulations on punishment of minors emerged. But the age of majority, the age limits of criminal liability and the age quantifying penalties underwent variations over time.

The law from the 17th century stipulated that the age of majority was 25 years. This category included the juvenile age groups that allowed various methods of punishment to be applied, and one of the criteria for determining criminal liability was sex. "*Cucon / cocoon*" was a minor under the age of seven years. *Young person* was a term booked for boys aged between twelve and a half and fourteen and girls aged between nine and twelve and a half (8, 9).

Minority limits remain unchanged until the early 1800s, when the child aged up to 7 years was not criminally liable. Penalties could be applied to minors aged 7 to 14 years and those aged 14 to 20 years, increasing the severity of penalties imposed as the minor got older. In *Legiuirea Caragea*, in 1818, a new age emerged for which exemptions to punishments were allowed, which is that of the "the not old" young (20-25 years old) who were entitled to ask the ruler for a sentence reduction (10).

In the 19th century the age of criminal responsibility was increased to 8 years old and the juvenile period was divided into age groups of 8-15 years old and 15-21 years old, juveniles of the latter category facing judicial situations unconditionally (10).

The first Romanian Penal Code (1865), provided that the minor is not criminally liable until the age of 8, and the juvenile period was divided into two groups: 8-15 years old and 15-20 years old (11).

In the Criminal Code of 1936 the coming of age was set at 19 years old, and was divided into two categories- child and adolescent- periods separated by the age of 14 (12).

In the Criminal Code of 1948, the terms child and adolescent were replaced by the term *minor*. The minor was the person who had not turned 18, and the age of criminal responsibility was lowered 14 to 12. A minor aged 12 to 15 was not held responsible for an act committed injudiciously (13).

The current limits for juvenile criminal liability were established in the Criminal Code of 1969. This stipulated that minors under the age of 14 were not criminally liable, those aged 14 to 16 were criminally liable if they did have discernment and those over 16 were criminally responsible (14).

THE SANCTIONING OF THE UNDERAGE OFFENDER- FROM PUNISHMENT TO EDUCATIONAL MEASURES

The Romanian law that provides criminal penalties for offenses committed by juveniles has evolved over time from punishing to coming up with educational measures and reintegration of offenders into the community. The overwhelming importance of the factors regarding family, education and society in the genesis of juvenile delinquency has gained increasing

relevance in modern criminal law.

In the 17th century, in case of crimes such as murder, robbery, sexual offenses or counterfeiting, committed by juveniles, the punishments were reduced compared to those applied in the case of adults even if the defendant was tried in adulthood. Lower punishment of juveniles was not, however, applicable in case of acts such as heresy or murder of a parent. 17th century legislation provided that young people aged 18 could be sentenced to prison. The 14 year-old ones who made a mistake for which adults were sentenced to death were publicly beaten and then sent to prison, and young people aged 14 to 25 who consciously committed criminal acts were beaten and sent to salt mines to do hard labor (8, 9).

In the early 1800s they separated the place for serving the sentence in the case of juvenile offenders and that of adult offenders, making it possible for juveniles aged 7-14 to be punished by imprisonment in the monastery. Imprisonment was possible for a maximum period of 10 years for minors aged 14 to 20 years for committing acts that attracted the death penalty for adults (10).

In the 19th century, in harmony with international law, beating was waived, juvenile prisons and those for adults were separated and a special jurisdiction for juvenile delinquents was created. Then there appear the first legal provisions allowing the sanctioning of minors aged 8-15 years who committed acts unwittingly, by measures of education within families. For acts committed with premeditation, however, juveniles of the same age were punished with solitary monastery confinement for 3 months up to 3 years (10).

In the second half of the 19th century, educational measures and penalties were maintained. Minors aged 8-15 who lacked discernment were not punished, but were entrusted to the parents or were taken to the monastery for re-education until they turned 20. The discerning minors or those between 15 and 20 years old could be sentenced to 3-15 years in prison for a crime that drew sentences of hard labor for life for an adult. For other offenses, the minor could be sentenced to at least one third or to more than half of an adult's sentence. Minors were judged by special courts and the sentence was carried out in special places (11).

At the beginning of the 20th century the first institutions for the re-education of juvenile offenders appear, such as the disciplinary colony from Mălureni, Argeş, designed for beggars and homeless minors or the Romanian Reformatory Education Institute in Gherla, for non-criminal and criminal minors after serving their prison sentence. In this institute the sentences of beating with a rod and solitary confinement were kept (10).

The judicial reform after the World War I led to a system of modern approach of juvenile offenders. The *Law for defeating vagrancy and begging and for the protection of children* (1921) and the *Law on prisons and preventive institutes* (1929) allowed the establishment of schools for re-education and protection, of labor colonies and correctional institutions, in order to ensure the qualification in a trade and the social reintegration of juvenile offenders (15, 16).

The Criminal Code of 1936 (12) mentioned that discerning juvenile offenders could be entrusted with their family, a close relative or *"an honorable person, a society of patronage or a public or private institution authorized by the State."* The minor

may also be placed under supervised release or admitted to an educational institute. Minors with psychiatric disorders could be admitted to a medical facility (hospice or nursing home) with the surveillance of a specialist, until "complete recovery".

For the discerning teenager, the court could apply educational measures (corrective education, supervised release) or punishment (reprimand, correctional prison, simple imprisonment).

In this period juvenile courts were established and correctional punishment or detention were executed in institutes for corrective education, where children were separated from teenagers and boys were separated from girls. Minors who could not adapt to joint treatment were subjected to a type of treatment which allowed them to be assigned individually or in a group of hospitalized inadaptable. Depending on the seriousness of the offense, imprisonment was also individualized to solitary confinement- night time and day time.

In the Criminal Code of 1948 the term *corrective education* was replaced with that of *moral rehabilitation* (13).

Since 1951 (18) educational colonies for minors with social adjustment problems were created by the Ministry of Internal Affairs, as well as regional and interregional reception points for children aged 3-18 (19).

The Criminal Code of 1969 (14) maintained educational measures and punishment, sanctions that could be imposed on juvenile delinquents, depending on the seriousness of the offense committed and on their physical, intellectual and moral development. The educational measures were: reprimand, supervised freedom, hospitalization in a rehabilitation centre or in a medical-educational institute. The minor could also be admitted to these institutions after the age of 18, up to 2 years.

Punishment, applied when educational measures failed, was imprisonment or a fine. Imprisonment limits were reduced by one third, without this exceeding a period of 5 years. For offenses punishable by death in adults, juvenile imprisonment would be applied from 5 to 20 years without the possibility of complementary sanctions as well, with the possibility of parole.

Compulsory social inquiry appears (called the *evaluation report* from 2006) meant to provide the judicial body with data concerning the minor and the prospects for social reintegration, based on the information about behavior and his personal pathological history and his family and social environment (20, 22).

The 2004 Criminal Code sanctions maintained punishment and educational measures, supplementing the latter with freedom under strict supervision. Also, the duration changed: 5-15 years for a crime punishable by life imprisonment in adults, 3-12 years for severe crimes, or halving the sentence but not more than 3 years. The minor could perform community service and could waive the penalty for offenses punished with imprisonment for not more than 2 years, in the case of minors without criminal records, who covered the damage they had caused and proved they could change without the necessity of a sentence (21).

The new Criminal Code, effective since 1 February 2014 (23), radically changes the consequences of criminal liability with respect to minors, leaving out penalties and keeping only educational measures. Educational measures may mean non-custodial (civic training course, supervision, weekend confinement and daily assistance) or deprivation of liberty (placement in an educational centre or in a detention centre),

depending on the seriousness of the offense and on the minor's peculiarities, their implementation being coordinated by the probation service.

The civic training course consists of the minor's commitment to participate in a four-month program in order to understand the legal and social consequences he is exposed to in case of criminal offenses and to be more aware of his behavior in the future. Supervision consists of controlling and guiding the minor in his daily program for a period of 2-6 months. For the weekend confinement, the minor is not allowed to leave the house on Saturday and Sunday, for a period 4-12 weeks. Daily assistance may be ordered for a period of 3- 6 months and it requires the minor to follow a schedule set by the probation service. In addition, obligations may be imposed, such as enrolling in training courses, submission to control measures, medical treatment and care. Disrespecting all of the above may prolong or worsen the educational measure or may lead to admission to an educational centre.

Admission to an educational centre requires the minor's hospitalization for a period of 1- 3 years in a specialized institution where he will attend a training program for school, vocational training and social reintegration. Relapse leads to prolonging the hospitalization period or to a more severe measure, and good behavior can motivate a non-custodial measure or educational release from the centre if the person is 18.

In the detention centre, a specialized institution with security and surveillance regime, the minors attend an intensive program of re-education. Admission is disposed over a period of 2-5 years or 5 -14 years when the offense committed is punishable by imprisonment for more than 20 years or life imprisonment in adults. Relapse attracts an extended hospitalization and good behavior can lead to a non-custodial measure or release from detention centre if the person is 18 years old. If anti-social behavior is maintained at the age of 18, the court may order the continuation of the educational measure in a prison.

CONCLUSIONS

Our study shows that the approach to juvenile delinquency in the current Romanian Criminal Code is the result of a long process of reflection of the legislators on adopting a different system of punishments for juvenile offenders and on creating special regulations concerning the prosecution, trial and enforcement of the decisions regarding them.

By eliminating the punishment from the penalties in the case of juvenile offenders and by focusing on educational measures, the current criminal code adheres to the international approach of juvenile delinquency, emphasizing the education and re-integration into the community at the expense of custodial sentences.

EPIDEMIOLOGY AND PATHOLOGY OF PAROTID TUMORS – FIVE-YEAR RETROSPECTIVE STUDY

EPIDEMIOLOGY AND PATHOLOGY OF PAROTID TUMORS – FIVE-YEAR RETROSPECTIVE STUDY (Abstract) **Aim:** To retrospectively analyze the epidemiological, clinical and pathological data of parotid tumors. **Material and methods**: Reassessment of the histologic diagnosis of parotid tumor in the patients admitted to the Oral and Maxillofacial Surgery Unit of the Iasi "Sf. Spiridon" University Emergency Hospital during 2009-2013. Data on gender, age, place of residence, location, size, surgical procedure type and histopatological type were recorded. **Results**: The risk of developing pleomorphic adenoma is 7.40 times higher in women and 4.08 times higher before the age of 50 years. The risk of Warthin tumor is 16.47 times higher in male patients and 3.58 times higher in urban patients. People older than 50 years have a 7.14 times higher risk of developing malignancy and rural people have a 2.41 times higher risk of developing cancer. Diabetes, obesity and systemic hypertension were not important risk factors in our study. **Conclusions**: According to this study age and the place of residence could be important predictors for parotid gland tumors. Since in Romania there are few epidemiological data regarding the parotid gland pathology, further cohort studies are needed for a better understanding of their clinical and pathological behavior. **Keywords**: PAROTID GLAND TUMOR, EPIDEMIOLOGICAL STUDY, PATHOLOGY.

Parotid tumors are a heterogeneous group of tumors accounting for 85% of all salivary gland tumors, 2-6% of the head-neck tumors and about 1% of all tumors. Several studies have analyzed the epidemiology of salivary gland tumors but only a few have investigated the parotid tumor pathology. Most of them were conducted on less than 300 cases. In a study by Ali et al. (1) on the characteristics of parotid tumors in Pakistan population besides demographic and histopathological data the authors also described the clinical complaints, fine needle aspiration cytology results and complications. In another study, Moeller et al. (2) considered also the imaging findings. A study from China conducted by Chan et al. (3) described the demographic data and the management and complications of parotid tumors. In another study the epidemiological data were completed by a survival analysis (4). In the Romanian literature there are a

few studies about salivary gland pathology, some of them being case reports (5), some describing only pleomorphic adenoma of parotid gland (6), but there are no epidemiological studies.

The aim of this study was a descriptive analysis of the epidemiological and morphological aspects of benign and malignant tumors treated at the Oral and Maxillofacial Surgery Clinic and diagnosed in Pathology Department of "Sf. Spiridon" Emergency Hospital Iasi, Romania during the period 2009-2013.

MATERIAL AND METHODS

In present study were analyzed 162 tumors, of which 116 (67.46%) benign tumors and 46 (32.53%) malignant tumors.

The histologic diagnosis of the patients with parotid tumors admitted during 2009-2013 to the Department of Oral and Maxillofacial Surgery, "Sf. Spiridon" University Emergency Hospital, Iasi was reevaluated. After fixation in buffered formalin 10%, neutral pH, biopsy specimens were processed using paraffin embedding and hematoxylin-eosin, van Gieson, Alcian blue and PAS staining methods. The age of the study patients ranged between 13 and 90 years. To describe the morphological pattern of parotid tumors we used the 2005 World Health Organization classification (7).

Our analysis was based on demographic data (gender, place of residence, age), clinical data (location of the parotid gland, size of the tumor, type of surgical procedure) and histopathological type of tumor (benign/malignant). All patients with missing data on one or more variables used in the study were excluded.

For univariate analysis we used Mann-Whitney U to compare average age and chi square test to compare gender, place of residence, tumor location, size and type of surgical procedure. For multivariate analysis we used Multiple Logistic Regression considering as variables the gender, age (≤ 50 years/ > 50 years), place of residence (urban/rural), parotid gland location (left/right), tumor size (≤ 4 cm/ > 4 cm), and type of surgical intervention (superficial parotidectomy/total parotidectomy/ extended parotidectomy). Data were considered significant at $p < 0.05$.

RESULTS

The gender distribution showed a slight male predominance (55%) (fig.1A). No statistically significant gender differences were found between benign and malignant tumors (p=0.339). Most patients with benign tumors were living in urban areas (58.62%) and most patients with malignant tumors in rural areas (63.04%) (fig. 1B).

The difference between the two groups was statistically significant (p=0.012). There was a slight predominance of right parotid location of benign tumors (52.58%) and a slight predominance on left parotid location of malignant tumors (53.33%). The difference was not statistically significant (p=0.163). The mean size of malignant tumors was greater for (4.36 ± 3.14 cm) than that of benign tumors (3.49 ± 1.8 cm). The difference was statistically significant (p=0.025) (tab. I).

The age of patients with benign tumors ranged between 13 and 86 years, mean age 50.3 ± 15.81 years, and of the patients with malignant tumors between 20 and 90 years, mean age 67.17 ± 14.62 years. There were 2 cases under the age of 18 years, both with pleomorphic adenoma (tab. I). Age group distribution showed that most of benign tumors occurred in patients aged 41-70 years while malignant tumors were more

frequent in patients aged between 61 and 80 years (fig.2). Age group difference between benign and malignant tumors was statistically significant (p=0.025) (tab. I).

Surgery type	Superficial parotidectomy No (%)	68 (72.34%)	13 (38.23%)	NS (p=0.355) (χ^2test)
	Total parotidectomy No (%)	4 (4.25%)	13 (38.23%)	
	Extended parotidectomy No (%)	22 (23.43%)	8 (23.53%)	

The multivariate analysis indicated a statistically significant difference between benign and malignant tumors in terms of age and place of residence and a significant difference between rural and urban area in terms of histopathological diagnosis.

Of the benign tumors the most common was pleomorphic adenoma (70%), followed by Warthin tumor (21%), and basal cell adenoma (7%) (fig. 3A).

In our study the most common primary malignant tumors were represented by acinic cell carcinoma (21%), squamous cell carcinoma (17%), adenoid cystic carcinoma (12%), adenocarcinoma NOS (12%), and carcinoma ex pleomorphic adenoma (12%) (fig. 3B).

In the present study the analysis of risk factors showed that gender, age and place of residence may influence the histologic type of parotid tumors. The risk of developing pleomorphic adenoma was 7.40 times higher in females than in males (OR=7.401, CI=2.76-19.82, p<0.0001) and 4.08 times higher before the age of 50 years (OR=4.085, CI=1.64-10.13, p=0.0016). The risk of developing Warthin tumor was 16.47 times higher in males than in females (OR=16.47, CI=3.65-74.17, p<0.0001) and 3.58 times higher in urban patients than in rural patients (OR=3.583, CI=1.23-10.37, p=0.01). The risk of developing cancer was 7.14 times higher in patients older than 50 years than in those under 50 years (OR=7.141, CI=2.63-19.36, p=0<.0001) and 2.41 times higher in rural patients than urban patients (OR=2.416, CI=1.19-4.88, p=0.012). Diabetes, obesity and systemic hypertension proved not to be important risk factors in our study. Due to incomplete data regarding the smoking habit this parameter could not be included in the study.

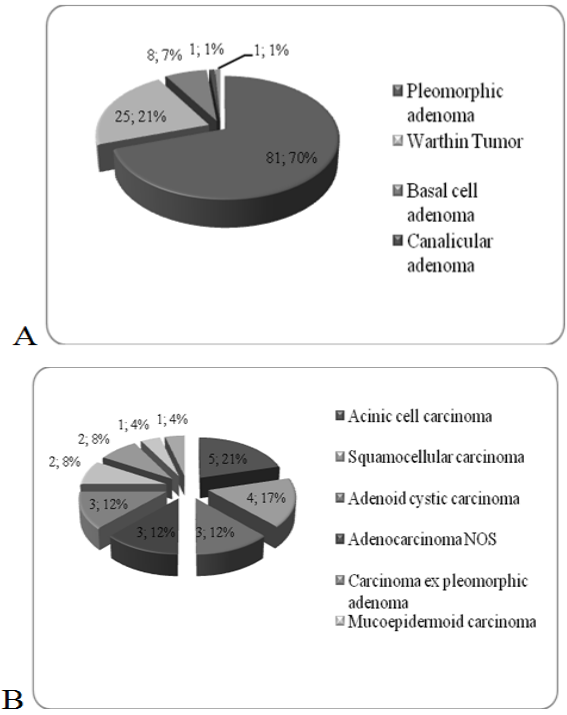

Fig. 3. Distribution of tumors: A. benign; B. malignant

DISCUSSION

There are many epidemiological studies regarding the salivary gland tumors, some of them the importance of parotid tumor pathology. Most of the studies are conducted on a limited number of cases and there are only few cohort series. Our paper presents the demographic data of the patients with parotid tumors diagnosed during the period 2009-2013 at the Oral and Maxillofacial Surgery Clinic and Pathology Department of the Iasi "Sf. Spiridon" University Emergency Hospital.

We found a male predominance which is consistent with other studies (1, 3, 4) but not with the study by Altinay et al. (8). Although, age distribution was similar with other studies (4, 8) in our patients mean age was a little higher. Unlike other reports (4) the majority of benign tumors were on the right side (52.58%) while most malignant tumors were on the left side (53.33%). The mean size of tumors in our study (3.49 cm for benign tumors and 4.36 cm for malignant tumors) was slightly greater than in other reports (3).

Using univariate and a multivariate analysis we found a predominance of benign tumor in urban areas (58.62%) and of malignant tumor in rural areas (63.04%), the difference being statistically significant (p=0.012). The lower utilization of medical services by the rural people could depend on their medical education, their trust in alternative medicine and a lower availability of medical services. This could be the cause for the delayed treatment of benign tumors with an increased risk of malignant transformation in these cases. Our study demonstrated that the risk factors were

represented by female gender and age less than 50 years for pleomorphic adenoma, male gender and urban residence for Warthin tumor, age over 50 years and rural residence for malignant tumors.

In terms of histopathological diagnosis the incidence of benign and malignant tumors is different in the international reports due to the great variability of study population. According to other studies (9, 10) 71% of the parotid gland tumors were benign and 29% malignant ones. In the present pleomorphic adenoma was the most common benign tumor, followed by Warthin tumor study which is agreement with other studies (1, 3). In case of malignant tumors the epidemiological data differed. Despite the low incidence of malignant tumors, five histopathological subtypes are considered the most frequent (11, 12). Thus, in some studies the most common types were mucoepidermoid carcinoma and adenoid cystic carcinoma (9, 13-16). Fonseca et al. considered adenocarcinoma Not Otherwise Specified (NOS) as the most common malignancy (10). A study in Taiwan indicated acinar cell carcinoma and mucoepidermoid carcinoma as the most frequent malignancies (3). The fifth more frequent carcinoma is carcinoma ex pleomorphic adenoma (12). Unlike these studies in our study the most common malignant tumors were acinic cell carcinoma, squamocellular carcinoma and adenoid cystic carcinoma. In our study there was a statistically significant difference ($p= 0.017$) between rural and urban residence in terms of tumor histological type.

CONCLUSIONS

Our study demonstrates that the age under 50 years is a risk factor for benign tumors, while the age over 50 years for malignant tumors. The patients residing in rural areas have a higher risk to develop malignant tumors due to a low utilization of health services. Since in Romania there are few epidemiological data on parotid gland pathology, further cohort studies are needed for a better understanding of their clinical and pathological behavior.

NEWS

RELATIONSHIP BETWEEN OBESITY AND ORAL DISEASES

The aim of a study realized by a group of researchers from University of Benin, Nigeria was to determine the relationship between obesity and periodontal status and dental caries experience of a group of nigerian dental patients. Participants were selected from patients attending dental outpatient clinics of the University of Benin Teaching Hospital, Benin City, Nigeria. Their weight and height were measured and body mass index (BMI) estimated in kg/m^2, gingival health assessed using bleeding on probing index, oral hygiene estimated using the simplified Oral Hygiene Index (OHI-S), periodontal health estimated using the Basic Periodontal Examination (BPE) and caries experience was estimated with the Decayed, Missing, Filled teeth (DMFT) index. A few participants (3.8%) were underweight, 52.6% fell within the normal BMI range, 28.2% pre-obese, 12.2% obese class I and 3.2% obese class II. The mean OHI-S score was 2.16 ± 1.13 among the overweight participants and 2.05 ± 1.13 among those who are not ($P = 0.543$). The mean DMFT score was 3.03 ± 4.25 among the overweight participants and 2.32 ± 3.01 among those who are not ($P = 0.223$). Sixty-five percent of participants with BPE score of 0, considered to signify periodontal health, had normal BMI while all the participants with the worst BPE score recorded belong to the obese 1 group ($P = 0.070$). The binary logistic regression revealed that the likely predictor of gingival bleeding in the study is BMI between 35.0 and 39.9 (obese class 2) ($P = 0.046$, odds ratio = 0.07, 95% confidence interval = 0.01-0.96). It can be concluded that there was no statistically significant relationship between obesity and periodontal status and dental caries experience in the studied group of dental patients. Increased body mass index may however be a predictor of gingival bleeding (Sede MA, Ehizele AO. Relationship between obesity and oral diseases. *Niger J Clin Pract*, 2014 ; 17 (6) : 683-690)

ANALYSIS OF ANTIBIOTIC RESISTANCE PATTERN OF *S.AUREUS* STRAINS ISOLATED FROM THE ORTHOPEDICS–TRAUMATOLOGY SECTION OF "SF. SPIRIDON" CLINICAL EMERGENCY HOSPITAL, IAŞI (Abstract): **Aim:** The retrospective analysis of antibiotic sensibility of *S.aureus* strains isolated from infected patients from the Orthopedics–Traumatology Clinic of "Sf. Spiridon" Clinical Emergency Hospital, Iaşi during January 2003–December 2013, in view of determining the evolution trend of the resistance phenomenon and of pinpointing the most useful treatment for these strains. **Material and method**: The antibiotic sensitivity test was carried out using two methods: diffusimetric–Kirby-Bauer and the MIC determination by E-test (for the strains isolated in 2013); the interpretation of the sensitivity was made in a standardized manner, in compliance with the CLSI (*Clinical and Laboratory Standards Institute*) standard for antibiotics testing in force. **Results:** The sensitivity testing for β-lactams proved that during the 11 years of the study, the average value of the frequency of resistant strains was of 41.59%±8.68. The highest frequency of MRSA (*Methicillin Restant S. aureus*) strains was noticed in 2012 (58.6%), followed by 2004 (50.7%). Even if in 2013 it dropped to 38.9%, the trend calculated for 2003-2013 is slightly rising (y=0.0073x+0.372). Out of the total of 495 *S.aureus* strains that were isolated, 164 (33.13%) were completely sensitive to the tested antibiotics and 26 (5.25%) were resistant only to β-lactams. The other MRSA strains associated multiple resistance and MIC for vancomycin varied between 0.5-2 mg/ml. Two strains whose MIC was of 0.5 mg/ml were sensitive to most classes of tested antibiotics, including β-lactams, except for macrolides (erythromycin), and the strain whose MIC was of 2 mg/ml, was resistant to all classes of tested antibiotics, except for glycopeptides and oxazolidiones. The other tested strains had a MIC for vancomycin equal to 1mg/ml. **Conclusions**: Due to the fact that there are infections with SAMR strains in a rather worrying percentage (53.9%) that are resistant to the other classes of antibiotics, the only therapeutic solution being the vancomycin treatment, its use should be limited solely to those cases when it is really necessary. Fortunately, no vancomycin resistant MRSA strains have been identified in our country, but this phenomenon should be kept under close surveillance. **Keywords**: MRSA, VANCOMYCIN, MINIMUM INHIBITORY CONCENTRATION, E-TEST

Hip or knee prostheses, fractures fixation, ligament or sinew reconstruction and other procedures requiring the use of an implant are very frequently used in view of repositioning the fractured bone segments and of recovering the articular function. Unfortunately, all these procedures are accompanied by a variable risk of infection, depending on the type of surgical intervention, ranging from 0.8% for arthroplasties and 53% for open fractures (type III Gustillo) (1). Osteoarticular infections are difficult to treat, being associated with a recurrence risk of 10-20% cases, especially in case of multi-resistant pathogens, such as methicilin resistant *Staphylococcus aureus* (MRSA). The possibility to come across a microorganism with antibiotic multi-resistance is a major concern for the clinician, in full awareness that an infection triggered by such a strain leads to the increase of morbidity and mortality (2). The retrospective analysis of the antibiotic sensitivity of *S.aureus* strains isolated from the infected patients in the Orthopedics–Traumatology Clinic of "St.Spiridon" Clinical Emergency Hospital, Iaşi from January 2003 to December 2013, in view of determining the evolution trend of the resistance phenomenon and of pinpointing the most useful treatment for these strains.

MATERIAL AND METHODS

The retrospective study was made for the period 01.01.2003–31.12.2012, and the result of the diffusimetric antibiograms was taken from the hospital's informatics system; the prospective component of the study implied the collection of pathological products from patients admitted during 01.01.2013–31.12.2013, for whom there was a suspicion of clinical infection, in compliance with the general norms of sampling products destined for the bacteriological exam. We excluded from the database the strains from the same bacterial species and with an identical phenotype of resistance to anti-infections chemo-therapeutic products as another isolated strain from the same patient during the same infectious episode. The strains were isolated and identified in the Microbiology Labs of "Sf. Spiridon" Hospital, Iaşi and of the Microbiology Discipline within "Grigore T. Popa" University of Medicine and Pharmacy, Iaşi. Antibiotic sensitivity testing was carried out using two methods: diffusimetric–Kirby-Bauer and MIC determination by E-test (for strains isolated in 2013), and the interpretation of the sensitivity was conducted in a standardized manner, in compliance with the CLSI standard (*Clinical and Laboratory Standards Institute*) for antibiotic testing in force on that date (3).

RESULTS

From January 2003 to December 2013 a number of 555 strains of staphylococcus were identified, 495 belonging to the *S.aureus* species, the rest of 60 strains being coagulase-negative staphylococci (CoNS). The *S.aureus* strains isolated were tested for the following antibiotics: AMC (amoxicillin + clavulanic acid), OXA (oxacillin), RIF (rifampicin), CAM (chloramphenicol), TEI (teicoplanin), VAN (vancomycin), LNZ (linezolid), GEN (gentamicin), PFX (pefloxacin), LVX (levofloxacin), CIP (ciprofloxacin), CLI (clindamycin), MFX (moxifloxacin).

Sensitivity testing for β-lactams proved that during the 11 years of the study, the average value of the frequency of resistant strains was 41.59%±8.68 (tab.1).

The highest frequency of MRSA strains

was observed in 2012 (58.6%), followed by 2004 (50.7%). Even if in 2013 it dropped to 38.9%, the trend calculated for 2003-2013 is slightly rising (y=0.7373x+37.167) (fig. 1). Following rifampicin sensitivity testing of isolated strains of *S.aureus* the average of the frequency of resistant strains for the whole duration of the study was of 32.09±10, and the yearly distribution showed a peak in 2004 (50.7%), the trend calculated for 11 years being descending (y=-2.1609x+44.093) (fig. 2).

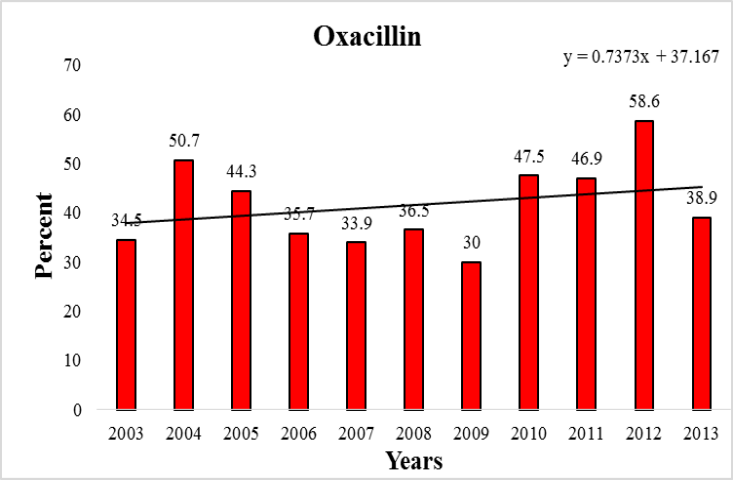

Fig. 1. Distribution of the frequency of MRSA strains on years of study

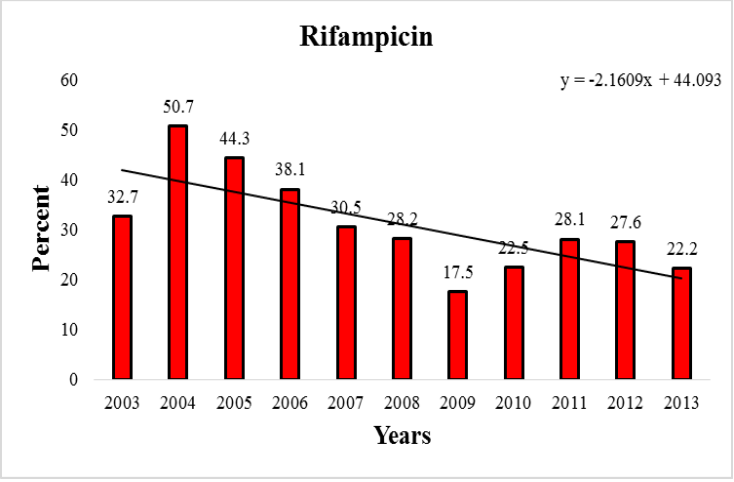

Fig. 2. Distribution of the frequency of rifampicin resistant *S.aureus* strains on years of study

Starting with 2004, the *S.aureus* strains were also tested for vancomycin and linezolid. Vancomycin sensitivity was 100% and for linezolid 100% during 2009-2013 and during 2004-2008 the percentage of resistant strains was extremely low (2004-

3%, 2005-4.9%, 2006-7.1%, 2007-1.7%, 2008-5%) (tab. I).

S.aureus strains were tested, depending on the year, for both 2nd generation quinolones, such as pefloxacin (2003-2006) and ciprofloxacin (2006-2013), and 3rd generation ones, such as levofloxacin (2004-2011) and moxifloxacin (2009-2011). The average of resistant strain frequency can be seen in table I. Both for ciprofloxacin, and for levofloxacin, the tendency of identifying resistant strains, calculated for the duration of the study, was descending (y=-4.45x±51.713 for levofloxacin and y=-1.83x±34.491 for ciprofloxacin).

TABLE I

Distribution on years of the frequency of *S.aureus* strains resistant to various antibiotics

Year	No. of isolated strains	AMC	OXA	TEI	VAN	LNZ	GEN	CIP	PFX	LVX	MFX	CLI	RIF	CAM

The percentage of clindamycin resistant *S.aureus* strains was variable. Sensitivity testing for this antibiotic started in 2007 and continued until 2013. If, in the first years, the percentage of clindamycin resistant *S.aureus* strains was relatively low (5.8%-10.2%), one can see in figure 3 that during the last two years their frequency increased approximately four times (44.8%-2012 and 38.9%-2013), the rising trend of resistance to this antibiotic being obvious (fig. 3).

Multiple antibiotic resistance has registered an increased incidence starting with 1950. The antibiotic classes that were tested *S.aureus* strains were: β-lactams, aminoglycosides, fluoroquinolones, lincosamides, rifampicin, glycopeptides and oxazolidinones. Taking into consideration the fact that all tested strains were sensitive to glycopeptides, and oxazolidinone resistance was extremely low, cross resistance was analyzed only in the case of the first five classes of antibiotics. Out of the 495 isolated

S.aureus strains, 164 (33.13%) were completely sensitive to all tested antibiotics and 26 (5.25%) were only resistant to β-lactams. The other MRSA strains associated multiple resistances: 16 (3.23%) of them showed resistance to only one antibiotic class, mostly aminoglycosides (e.g. gentamicin) – 10 strains (2.02%); 103 strains (20.8%) associated resistance to two other antibiotic classes, the most frequently used being aminoglycosides and rifampicin – 92 strains (18.58%).

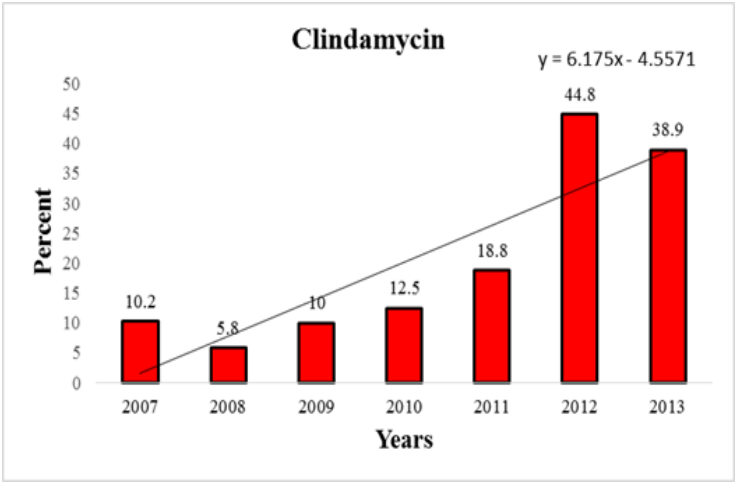

Fig. 3. Distribution of the frequency of clindamicyn resistant *S.aureus* strains on years of study

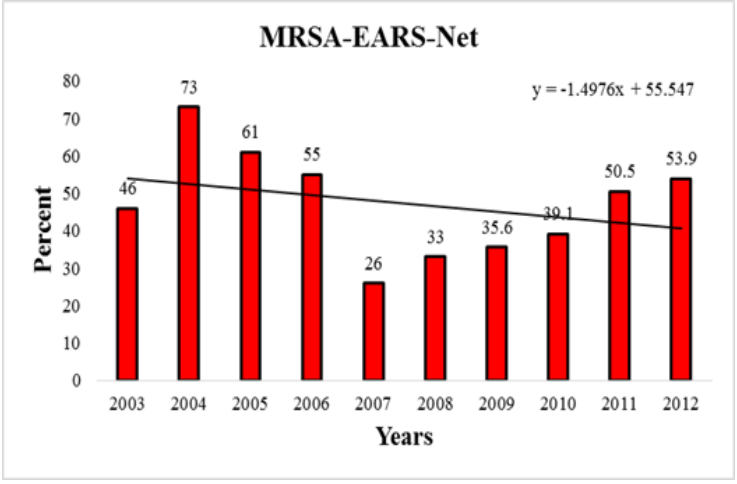

Fig. 4. Distribution of frequency of MRSA strains according to the data from EARS-Net

Associated resistance to four antibiotic classes could be determined only starting with 2007, when the *S.aureus* strains began to be tested for clindamycin. 35 strains (7.07%) fell into this category, most of them associating resistance to lincosamides

as well. We registered a number of 23 strains that were sensitive only to glycopeptides (4.64%).

For 18 strains of *S.aureus* isolated in 2013 we used the E-test to determine the MIC for vancomycin, which varied between 0.5 -2 mg/ml. Two strains whose MIC was of 0.5 mg/ml were sensitive to most tested antibiotic classes, including β-lactams, except for macrolides (erythromycin) and the strain whose MIC was of 2 mg/ml, was resistant to all tested antibiotic classes, except for glycopeptides and oxazolidinones. The other tested strains had a MIC for vancomycin equal to 1mg/ml.

DISCUSSION

The antibiotic sensitivity test showed high resistance levels to antimicrobial agents, with the presence of clinically and epidemiologically important phenotypes, among which the high incidence of MRSA strains (41.59%) stands out as well as the increased incidence of MDR phenotypes (31,11%). Methicillin resistant *Staphylococcus aureus* is the most important cause of infections associated to medical care round the world. In 2009, only six countries in Europe reported decreasing trends for MRSA. In 2012, although the problem seems to have been stabilized or even to have decreased in certain European countries, MRSA remains a public priority as the proportion is still over 25% in more than 1/3 of the countries (4). The latest data from EARS-Net (European Antimicrobial Resistance Surveillance Network) (2012) indicate for Romania and Portugal (the only countries in Europe with this level of resistance) a MRSA percentage of over 50% (Romania 53.9%, Portugal 53.8%). According to our study, in 2012, the percentage of MRSA strains was of 58.6%, but in 2013 it fell under 40% (38.9%).

Upon analysis of the EARS-Net reports for 2003-2012, we assessed that: the highest frequency of MRSA was registered in 2004 (73%), followed by a marked decreased until 2007, namely 26%, in turn followed by a continuous increase until 2012, when it exceeded 50% (namely 53.9%). However, it seems that the trend calculated for 2003-2012 is slightly decreasing (y=-1,4976x+55.547) (fig 4).

By comparing the data supplied by EARS-Net and the data obtained by us, there is no statistically significant difference (t=-1,495, GL=9, p=0,169). With regard to the results concerning RIF resistance, except for 2009, when the frequencies were roughly equal (17.5% in our study and 15.6% - EARS-Net), in the other two years an increase of the incidence of RIF resistant strains was registered in our area, as compared to the data supplied by EARS-Net (2010 – 22.5% vs. 13.3%, 2011 – 28.1% vs. 7.9%).

For 2012, in Europe, the percentage of MRSA strains varied from 0.7% in Sweden to 53.9% (Romania). Except for Sweden, there are five other countries in Europe which show a percentage of SAMR strains ranging between 1.3 – 2.1%, most of them having a MRSA frequency between 10 – 25% (14 countries) (4). In addition, the same 2012 report supplies data according to which the RIF resistance for MRSA strains was of 5-7% and for MSSA (*Methicillin Sensitive S. aureus*) strains of only 0.6%. In our study, RIF resistance associated to MRSA strains was of 73.52% for the whole duration of 11 years of the study and of 47.06% for 2012, while for MSSA strains for the same period it was of 9.34%, except for 2012, when all strains were sensitive.

According to the same EARSS report (from 2013) regarding the antimicrobial resistance in Europe for 2012, the MRSA strains associated resistance to fluoroquinolones of 81% as compared to MSSA strains, with only 6%. In our study, in 2012, isolated MRSA strains associated a resistance to fluoroquinolones of 35.3% and in 2013 of 71.42%, while MSSA strains were completely sensitive to fluoroquinolones, both in 2012 and in 2013.

Although there are certain countries which militate for the use of other antibiotics than VAN, there isn't sufficient evidence in the published randomized studies to indicate their superiority (5, 6). The data showing the efficiency of any antibiotic other that VAN in the treatment of serious infections caused by the strains whose MIC for vancomycin is situated in the "highly sensitive" area are even more limited. There is a study carried out by Soriano and col. which concluded that a MIC > 1mg/l to vancomycin through E-test is considered to be among the risk factors associated with a high mortality, but only in the case of patients who were treated empirically with vancomycin (7).

Similarly, Hidagat and col. reported that 12 out of 15 patients (80%) with MRSA determined infections, whose MIC for vancomycin was high and who failed to respond properly to the treatment with this drug, had good results when another antibiotic was used (8).

The guides for monitoring vancomycin therapy for 2009 of the Pharmacists' Society in USA recommend alternative solutions for the treatment o MRSA infections, if MIC $\geq$ 2mg/l (9). On the other hand, more recent guides (2011) recommend for strains whose MIC $\geq$ 2mg/l, that the decisional factor in continuing vancomycin therapy should be the patient's response, independently from MIC (10).

In conclusion, due to the fact that there are MRSA infections in a worrying percentage (53.9%) that are resistant to the other antibiotic classes, the only therapeutic solution being the vancomycin treatment, its use should be limited only to those cases when it is strictly necessary. Fortunately, in our countries vancomycin resistant MRSA strains haven't been yet identified, but the constant surveillance of this phenomenon is a must.

ANTIMICROBIAL ACTIVITY OF NOVEL 5-AMINOIMIDAZOLE-4-CARBOXAMIDRAZONES

Ribeiro et al. developed a method to prepare a series of fifteen 5-aminoimidazole 4-carboxamidrazones, starting from 5-amino-4-cyanoformimidoyl imidazoles. When testing the antimicrobial activity of these novel amidrazones against *Candida* sp. (*C. albicans*, *C. krusei*, *C. parapsilosis*) and Gram positive (*Staphylococcus aureus*) and Gram negative (*Escherichia coli*, *Pseudomonas aeruginosa*) bacteria, all inhibited the growth of *Candida* sp and a subset of compounds displayed fair-moderate activity against *S. aureus* and *E. coli*. The most potent antifungal compounds were also tested against *Cryptococcus neoformans*, *Aspergillus fumigatus*, *Trichophyton rubrum*, *T. mentagrophytes* and *Microsporum gypseum*, showing good activity aganist *C. krusei* and *C. neoformans*, but less on filamentous fungi when compared to their activity on yeasts. (Ribeiro AI, Gabriel C, Cerqueira F et al. Synthesis and antimicrobial activity of novel 5-aminoimidazole-4-carboxamidrazones. *Bioorg Med Chem Lett*. 2014. pii: S0960-894X(14)00856-7. doi: 10.1016/j.bmcl.2014. 08.025.)

CLINICAL-EPIDEMIOLOGICAL STUDY ON ADVANCED NON-SMALL CELL LUNG CANCER **(**Abstract). **Aim:** To assess the clinical and epidemiological features of all three main histological types of non-small cell lung cancer (NSCLC). **Materials and methods:** The study included 34 patients with NSCLC admitted to specialized units of the Iasi Regional Cancer Institute (IRCI) in the interval May 2012 - May 2014. Data were collected electronically based on a clinical-epidemiological survey form. The obtained data were then processed and interpreted by statistical-mathematical methods using the correlation index (significant at $p \leq 0.05$ and highly significant at $p < 0.005$), chi-square and Y tests. Data were analyzed using *SPSS 13.0* (SPSS Inc. Chicago, Illinois, USA). **Results:** Most NSCLC patients were aged 56-71 years, the Pearson correlation index between age and diagnosis being $p = 0.01$. Sex difference was highly significant ($p=< 0.001$) and so was the relationship between heavy smoking and age groups. Most cases were histogenetically classified as adenocarcinomas (22%). Four patients (21%) were in stage IIIA NSCLC, 4 (21%) IIIB, 9 (47.3%) IV, and 15 (79%) unspecified stage. All patients received primary chemotherapy. Single or associated complications included anemia and other hematologic disorders (26-74.6 %), respiratory failure, hemoptysis, cachexia, atelectasis, etc. Surgery was performed in 5 (14.7%) stage IIIA NSCLC patients. **Conclusions:** NSCLC showed a highly significant predominance in the age groups 56-71 years, and the most common histologic type was adenocarcinoma. All patients received primary chemotherapy, and patients with stage IIIA underwent surgery. Anemia and other hematologic disorders were the most common complications**.** **Keywords**: CLINICAL-EPIDEMIOLOGICAL, CANCER, NON-SMALL CELL LUNG CANCER.

By its high incidence and mortality lung cancer is one of the most common human malignancies. Thus, in the European Union the incidence of lung cancer exceeds annually 50/100,000 people, 82.5 in men and 23.9 in women.

In Romania, lung cancer has a mortality rate of about 60/100,000 people in men and 14/100,000 in women (1, 2). Of all lung cancers, 80-85% are non-small cell lung cancer (NSCLC), with the three major histological subtypes (squamocellular – 50%, adenocarcinoma – 15%, anaplastic – 15%), but with similar biological, clinical

and therapeutic features.

Clinical manifestations range widely from a small number of asymptomatic cases to cases presenting local tumor growth, regional spread, metastatic dissemination, and presence of paraneoplastic syndromes (3, 4, 5).

This study aimed to assess the clinical and epidemiological features of a series of patients with NSCLC admitted to specialized units of the Iasi Regional Cancer Institute (IRCI) (6, 7).

MATERIAL AND METHODS

This clinical-epidemiological study included a series of 34 patients with NSCLC admitted to IRCI in the interval May 2012 - May 2014. The patients were aged 52-81 years, 26 (76.4%) of them belonging to age group 56-75 years; 32 (94.1%) were men and 2 (5.9%) were women; over 80% resided in urban areas.

Data were collected electronically based on a clinical-epidemiological survey form, and were then processed and interpreted using statistical-mathematical methods: Pearson correlation index, significance ($p = 0.05$) and highly significant ($p < 0.005$), and chi-square, Y tests, CI = 95%_tests; data were analyzed using *SPSS 13.0* software.

RESULTS AND DISCUSSION

Age-group distribution showed that the majority of NSCLC patients were aged 56-71 years (26-76.4%), the study patients covering all 7 age groups (fig. 1).

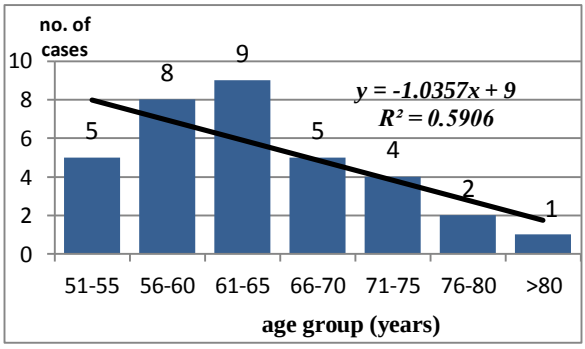

Fig. 1. Age-group distribution of the study patients

Pearson correlation index between age and diagnosis was $p=0.01$, which is consistent with our epidemiological data showing that 26 (76.4%) of our cases belonged to age group 56-75 years, and in agreement with data in other studies (32 - 94.1% *vs.* 2 - 5.9%) ($p < 0.001$).

Twenty-nine patients (85.3%) of the 34 study patients had a history of heavy smoking for at least 2-3 decades; all these patients were men, distributed quite evenly over all age groups, and with a very strong statistically significant correlation ($p < 0.0001$). Our data are consistent with those reported by many epidemiological studies (8, 9).

Adenocarcinoma was the most common type according to histogenetic classification (22 - 64.7%), followed by squamous cell carcinoma (8 - 23.5%) and large cell carcinoma (4 - 11.8%) (tab. I).

Histologic grading (WHO) was carried out in 7 (20.6%) cases (G2: 2-28% and G3: 5 - 71.4%).

TABLE I
Percentage validation of the cases based on histogenetic classification

Valid	Frequency	Percent	Valid percent	Cumulative percent
Adenocarcinoma	20	58.8	58.8	58.8
Squamous carcinoma	7	20.6	20.6	79.4
Others	7	20.6	20.6	100.0
Total	*34*	*100.0*	*100.0*	-

Staging at the time of diagnosis was carried out in 19 (55.9%) of the 34 patients enrolled in the study: 4 (21%) patients were in stage IIIA, 6 (31.6%) in stage IIIB, 9 (47.3%) in stage IV and 4 (21%) unspecified stage (tab. II).

TABLE II
Percentage validation of the cases based on disease staging

Valid	Frequency	Percent	Valid percent	Cumulative percent
IIIA	4	11.8	11.8	11.8
IIIB	6	17.6	17.6	29.4
IV	9	26.5	26.5	55.9
Unspecified	15	44.1	44.1	100.0
Total	*34*	*100.0*	*100.0*	-

Histological classification and staging together with the objective and subjective clinical findings guided the therapeutic approach.

All 34 patients included in the study and follow received primary chemotherapy with cytostatic agents active against NSCLC according to the guidelines of the sixth edition of AJCC Cancer Staging Manual, New York, Springer, 2000 (11, 12, 13, 14).

Various complications were recorded in 26 (76.4%) of the 34 study patients (15, 16, 17, 18) (tab. III, IV).

TABLE III
Complications recorded in the 34 patients with NSCLC (single or associated)

Category	No. of cases	%
Anemia	14	41.7
Other hematologic disorders	12	35.3
Respiratory failure	8	23.5
Hemoptysis	4	11.8
Cachexia	4	11.8
Other complications (lung abscess, atelectasis, lymphangitis, perithoracic phlegmons)	1 case each	-

TABLE IV
Percentage frequency of complications

Valid	Frequency	Percent	Valid percent	Cumulative percent
Yes	26	76.5	76.5	76.5
No	8	23.5	23.5	100.0
Total	*34*	*100.0*	*100.0*	-

Surgery was performed in 5 (14.7%) patients with stage IIIA resectable NSCLC as it is recognized to have superior therapeutic benefits (19, 20).

CONCLUSIONS

Lung cancer represents the most important neoplasia, in Romania.

The increased incidence of adenocarcinoma histologic subtype is highlighted in our study, too. Advanced stages are predominantly associated with co morbidities due to the evolution of neoplasia, but certain complications.

ELECTRONIC MEDICAL RECORDS - AN IMPERFECT SYSTEM WITH GOOD RESULTS FOR IDENTIFYING PATIENTS WITH A COMMON PHENOTYPE

The objective of this review was to summarize literature describing approaches aimed at automatically identifying patients with a common phenotype. The authors performed a review of studies describing systems or reporting techniques developed for identifying cohorts of patients with specific phenotypes. Every full text article published in (1) *Journal of American Medical Informatics Association*, (2) *Journal of Biomedical Informatics*, (3) *Proceedings of the Annual American Medical Informatics Association Symposium*, and (4) *Proceedings of Clinical Research Informatics Conference* within the past 3 years was assessed for inclusion in the review. Only articles using automated techniques were included. The identification of patients who satisfy predefined criteria from a large population in an institution has numerous use cases, including clinical trial recruitment, outcome prediction, survival analysis, and other kinds of retrospective studies. However, the process of distinguishing these patients on the basis of their patient records can be extremely time-consuming and challenging depending on the complexity of the criteria. This is because the data matching these criteria are buried within multiple documents and across multiple data points in the electronic health record (EHR) of a patient. Some data, such as laboratory results, medications, and diagnoses, have a structured format. The ability to extract meaningful pieces of information from the EHR and consolidate them into a coherent structure would provide great value for automatically identifying patient cohorts that satisfy complex criteria. Studies in this review addressed different diagnoses as the phenotype of interest. A large number of papers focused on diabetes, cancer, heart failure, rheumatoid arthritis, or cataract. A few studies described generic methods that could be applied to multiple diagnoses. Several papers addressed identification of adverse drug events. Some studies also analyzed genomic data of a predetermined phenotype to gain insight into other phenotypic properties of the same cohort. Authors have developed a top of the first 10 phenotypes of interest. Although cancer has been reported as a generic phenotype, there were 12 types of cancer (with breast cancer being most prevalent) studied in seven articles. Congestive heart failure and heart failure were counted as the same phenotype. Similarly, hypertension and resistant hypertension were considered to be one phenotype. Some articles also considered other observable characteristics such as smoking status and obesity among patients. Pneumonia and a variety of other infectious diseases were studied. This review is not without limitations, especially for the vagueness of the term phenotyping, meaning that there is no exhaustive search strategy for retrieving appropriate articles across the entire available body of biomedical literature. However, because of the venues considered and the recent popularity of this topic, this review is representative of past and present efforts in this domain. (Shivade C, Raghavan P, Fosler-Lussier E, Embi PJ, Elhadad N, Johnson SB, Lai AM. A review of approaches to identifying patient phenotype cohorts using electronic health records *J Am Med Inform Assoc* 2014;**21**:221-230 doi:10.1136/amiajnl-2013-001935).

EXAMINATION OF BOLTON INDEX COMPARING THE TRADITIONAL METHOD WITH A 2-DIMENSIONAL DIGITAL MEASUREMENT METHOD (Abstract): The Bolton Index is one of the most important analyses in orthodontic treatment planning. It shows if there is a correct proportion in size between the maxillary and mandibular teeth. In this study we compared the digital and traditional method. **Methods**: 35 dental casts were measured using a Vernier caliper. The mean value was compared with the measurements from the scanned images of the dental casts. **Results**: The results showed that the digital method provided similar results with those of the traditional one with a mean difference of 0.23 mm. The Pearson correlation coefficients were very high and similar to each other: R=0.989 and R=0.988 for the Anterior Bolton Index (ABI) and Overall Bolton Index (OBI), respectively. No statistically significant differences were present from either the ANOVA or the paired t-tests. **Conclusion**: The used digital method is as accurate as the traditional one, it is faster and easier to carry out and it offers all the advantages of image storage and data for subsequent use. **Keywords**: BOLTON INDEX, TRADITIONAL METHOD, DIGITAL METHOD.

In 1958, Bolton (1) studied 55 patients with excellent occlusions and produced ratios for the mesiodistal sizes of maxillary and mandibular teeth. He introduced two indices: the Anterior Bolton Index (ABI) which is the percentage obtained by adding the mesiodistal size of the six mandibular anterior teeth (from canine to canine) divided by the mesiodistal size of the six maxillary anterior teeth (from canine to canine); and the Overall Bolton Index (OBI) which is the percentage obtained by dividing the total mesiodistal size of the 12 mandibular teeth (from first molar to first molar) by the mesiodistal size of the maxillary teeth (from first molar to first molar). The indices for a correct occlusion, extrapolated from Bolton`s studies. (2)

ABI= 77.2 per cent (74.5- 80.4 per cent)
OBI= 91.3 per cent (87.5- 94.8 per cent)

In 1962, Bolton (3) reviewed his original study. He presented several clinical cases to determine if his analysis was viable diagnostic aid and determined that by employing the analysis, there is rarely a need for a diagnostic setup. (4)

Computer aided analysis of tooth size discrepancy was investigated by Tomassetti et al., (2001) who compared manual measurements with Vernier callipers to the QuickCeph Image programme, the Hamilton Tooth Arch System software (HATS) and the OrthoCad software. Measurements with the HATS system had the highest degree of correlation to Vernier callipers, with 86.4% of the measurements for the overall ratio being within 1.5mm of the vernier calliper measurements, followed by OrthoCad and QuickCeph. QuickCeph was found to be the fastest method of measurement at 1.85minutes, followed by the HATS system at 3.4minutes, OrthoCad at 5.37minutes and finally Vernier callipers at 8.06 minutes. (4)

MATERIAL AND METHODS

Thirty five dental casts of patients attending the Orthodontic Department of the University of Medicine and Pharmacy Targu-Mures, were selected.

In order to compare the two measuring procedures under the best condition, the selection criteria of the casts were:

1. A permanent dentition from first molar to first molar
2. Good quality casts
3. No tooth agenesis or extractions
4. No large restorations that could change the mesiodistal diameters of the teeth
5. No teeth with anomalous shapes.

The mesiodistal sizes of the upper and lower teeth of each cast were measured by both methods as follows: for the traditional method callipers were used to measure the mesiodistal size of the cast. The ABI and OBI of these mesiodistal sizes were calculated by totalling the sizes of the teeth and determining the corresponding index. Three measurements were carried out in one month period with at least two weeks between each measurement and the order in which the casts were presented was changed.

For the digital method the casts were scanned. Digitization was carried out by placing the stone dental casts on a scanner (Konica Minolta, Bizhub C554), surrounded by a sheet of millimeter graph paper. This enabled the calibration of the two axes and thus calculation of the ABI and OBI. The scanned image was then scaled so that two different vertical and horizontal marks on the squared paper were selected at a specific distance of 30 mm apart, to establish both the horizontal and vertical transformation dimension factors. These transformation dimension factors (the horizontal factor `x` and the vertical `y`), which must have the same value, serve as verification. If the transformation dimension factors obtained are the same for the `x` and `y` axes, the calibration has been correctly carried out and the image has not been distorted; the equivalence relationship of the original cast model has been maintained but has simply been made larger.

STATISTICAL METHOD

A statistical package (IBM SPSS Statistics 20) was used to analyze the data obtained with the traditional and digital method which were presented as an Excel page. Absolute differences and Pearson correlation coefficients were used to compare the 3 sets of measurements made with Vernier calipers between each other and with the digital method. Repeated-measures analysis of variance (ANOVA) testing and

paired t-testing was performed on the same sets of data. A significance (P) value of .05 was used for each test.

RESULTS

Vernier calipers

Comparing the overall discrepancy for the first set of Vernier caliper measurements to the second set of Vernier caliper measurements showed that 85.7 % of the calculations were within 0.7 mm of each other. The mean difference was 0.38 mm, and the range was 0.00 mm to 1.28 mm. The Pearson correlation coefficient (R value) was 0.975. For the anterior discrepancy, the differences ranged from 0.00 mm to 1.18 mm with a mean of 0.47 mm twenty eight of 35 measurements (80 %) were within 0.7 mm, and the R value was 0.961.

Comparing the first and third set of models the results were similar. For the overall discrepancy, 94.2% of the measurements fell within 0.7 mm of each other with a range odd 0.02 mm to 0.82 mm and a mean of 0.28 mm. The R value was 0.985. For the anterior discrepancy, 91,4% of the measurements were within 0.7 mm, with a range of 0.00 mm to 0.84 mm and a mean of 0.29 mm. The Pearson correlation coefficient was 0.979.

The second and third sets of measurements were compared. For the overall discrepancy 94,2% of the differences were within 0.7 mm, and the differences ranged from 0.00 mm to 0.96 mm. The mean difference was 0.31 mm and the R value was 0.985. For the anterior discrepancy, 94,2 % of the results were within 0.7 mm. The mean difference was 0.33 mm, and the range was 0.02 mm to 1.18 mm. The Pearson coefficient was 0.981.

Digital method *vs*. Vernier calipers

The digital overall analysis differed from the ones made with caliper by a mean of 0.23 mm. The variations ranged from 0.00 mm to 0.95 mm, with 97.1 % within 0.7 mm.

For the anterior analysis the mean difference was 0.27 mm, with a range from 0.02 mm to 0.74 mm. Thirty four of 35 (97.1%) were within 0.7 mm.

The R value for the overall discrepancy was 0.989 and for the anterior discrepancy was 0.988.

No statistically significant differences were present from either the ANOVA or the paired t-tests. The P values for the paired t-tests were .091 for the overall discrepancy and .080 for the anterior discrepancy. For the ANOVA, the P value was .061 for the anterior discrepancy and for the overall there were no statistical differences between groups.

DISCUSSION

The importance of tooth size discrepancies in orthodontic diagnosis has been widely reported in the literature and accepted by the orthodontic community because the relationship between the upper and lower anterior dentitions is related to orthodontic finishing excellence.

Traditionally a Vernier caliper or needle-point divider is used to measure teeth and complete a tooth size analysis. Sheridan (2000) (5), reported that the Bolton Index was the most widely used diagnostic tool in clinical practice. However as determining this index with traditional measuring methods is laborious, it is not undertaken for more than half of the cases in clinical practice.

The OBI results with both methods showed concordance for all thirty-five patients (four patients with and thrity-one without discrepancies in the OBI). The ABI results were similarly very good, the find-

ings for all thirty-five patients concurring with both methods (six patients with and twenty-nine without discrepancies for the ABI). For the deviations in the measurements a variety of reasons could be responsible. First, the operator was less familiar with the digital system than with the calipers. The investigator found it difficult to pinpoint the exact mesial and distal points to be used for the measurements on the scanned images. Additionally, the closer the points were on adjacent teeth, the harder the task of distinguishing them. (4)

The aim of this study was to determine the accuracy and efficiency of performing Bolton`s tooth-size analysis using manual measurements with a Vernier caliper with computerized methods. The results obtained are in correlation with those in dental literature. Paredes (2006) (2) made a similar study and found that the correlation coefficients of the two methods were very high and similar to each other R=0.976 for ABI and R= 0.979 for OBI. The results also showed more discrepancies in the ABI than in the OBI using both methods. Tomasetti et al. (4) compared the traditional method with three digital systems: OrthoCad, HATS and QuickCeph. The HATS analysis had very similar results when compared with the averaged Vernier caliper measurements, The R value for overall discrepancy was 0.885 and for the anterior discrepancy 0.825. OrthoCad has slightly less correlated results, and the differences were of a greater magnitude. The R values for the overall and anterior discrepancies were 0.715 and 0.574 respectively. QuickCeph analyses were the least correlated of the 3 methods compared with the Vernier calipers. The R values for the overall and anterior discrepancies were 0.432 and 0.439 respectively. Distinguishing the proper landmarks was difficult with both the OrthoCad ad QuickCeph systems. In his review, Houston (6) stated that perhaps the greatest source of random errors is difficulty in identifying a particular landmark or imprecision in its definition.

CONCLUSION

The used digital method is as accurate as the traditional method for determining the Bolton indices. It is faster and easier to carry out and it offers all the advantages of a computer method, such as the storage of images and data for subsequent use

STUDY ON ERYTHROCYTE AGGREGATION USING COMPUTERIZED IMAGE ANALYSIS METHODS (Abstract). **Aim**: To study the relationship between erythrocyte aggregation and physical parameters: temperature and pH. **Material and methods:** Aggregation was evaluated using computerized image analysis by Aggregate Shape Parameter (ASP), defined as the ratio of the aggregate projected area to its square perimeter, and erythrocyte aggregation index (EAI). EAI was measured and compared at different temperatures (4ºC, 20ºC, 37ºC) and different pH values (3, 5, 7 and 9). **Results and discussion:** The results show that the increase in temperature induces EAI increase and a decrease in Ph, a decrease of erythrocyte aggregation. It was found that, at pH=3 and 5, erythrocytes are destroyed and, at pH=9 RBC clusters are formed. **Conclusions:** RBC aggregate shape reflects intercellular interaction and its quantification may thus be another characteristic of RBC aggregation. Increased RBC aggregation was observed in various pathological states, such as diabetes and myocardial infarction, or following trauma. **Keywords:** ERYTHROCYTE AGREGATION, COMPUTERIZED IMAGE ANALYSIS, TEMPERATURE, pH.

Red blood cell (RBC) aggregation has an important role in blood flow, particularly in the microvascular system. The flow in small blood vessels is particularly sensitive to the aggregate size and shape.

Normal RBCs in low-flow states or stasis form rouleau aggregates, while abnormal RBC aggregation may form an irregular aggregate structure. The irregular shapes may reflect abnormal cell-cell interactions between the RBCs. These abnormalities may be induced by cell-associated factors, such as reduced levels of membrane sialic acid (1), or extracellular factors, such as high levels of plasma immunoglobulin on the cell surface (2), as well as by temperature, pH, osmolarity (3,4), and ionic strength of the extracellular medium.

The morphology of RBC aggregates is related also to RBC deformability. When two cells collide, the point-to-point attachment between RBCs develops into surface-to-surface contact by membrane rotation and a rolling movement of the attached cells to form the rouleau structure (1).

When the deformability of the attached cells is reduced, or the rolling process is too slow to be completed before collision with the next cell occurs, an irregular aggregate will be formed. Thus, RBC aggregate morphology may reflect the cell deformability (5). It may be concluded that RBC aggregate shape reflects intercellular interaction, and its quantification may thus be another characteristic of RBC aggregation.

In this study, the morphology of RBC aggregates was studied by using the computerized image analysis method.

MATERIAL AND METHODS

For this study we used computerized image acquisition and processing system (fig.1). The main part is an optical microscope to which a digital video camera is attached.

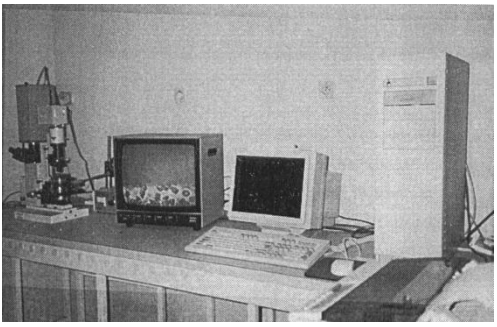

Fig. 1. Analysis system

EAI was determined using the Mchedlishvili's relation which establishes the total area of aggregated and not aggregated cells.

EAI is defined by equation no.1.

$$EAI = \frac{S_{agrg}}{S_{tot}} \cdot 100 \qquad (1)$$

The aggregate morphology is characterized by a dimensionless RBC Aggregate Shape Parameter (ASP) defined by equation no. 2:

$$ASP = 4\pi A/P^2, \qquad (2)$$

where A is the projected area of the aggregate and P is the perimeter of the projected aggregate. Since a circle has the maximal ratio of area to perimeter, this definition attributes to all aggregate structures ASP values between 0 and 1.

We studied the modifications that interfere in the process of erythrocyte aggregation due to variation in temperature and pH. In order to do the test we took into consideration 3 temperature values: 4 ºC, 20 ºC, 37 ºC. For each temperature we used tests from 6 patients. To determine EAI and ASP, 10 images from each test were processed.

In order to determinate the EAI we had to take into consideration the areas of the surfaces occupied by the aggregated and not aggregated cells. First, the total aria S_{tot} occupied by erythrocyte (aggregated and not aggregated) was calculated and then, through the elimination of the isolated cells (not aggregated), the area of the aggregated cells S_{agreg} was determined. Using the Simagis 3.0 (Smart Imaging Technologies) software, these arias were found beginning with the initial image.

RESULTS

Study of erythrocyte aggregation for different values of temperature.

This is a relevant example for 4 ºC temperature (fig. 2). The images were processed using Simagis (fig. 3).

94.5482	98.2622	99.5559

Study of the erythrocyte aggregation for different pH values.

Another study was conducted in order to determine the changes in erythrocyte aggregation depending on pH. In order to do the test we took into consideration 4 pH values: 3, 5, 7 and 9.

Like in the temperature study we processed 10 images each. At pH = 3 and 5 the cells were destroyed and EAI could not be detected (fig. 4). No rouleaux were formed.

For a normal pH = 7 RBC rouleaux were formed. EAI was determined using the same procedure as in the temperature study.

It is to be noticed that at pH = 9 tridimensional rouleaux could form (fig. 5). In this case clusters were also found.

TABLE II.
Mean EAI values depending on Ph

Erythrocyte Aggregation Index	
pH = 7 (n = 60)	pH = 9 (n = 30)
98.5916	99.4342

DISCUSSION

The results show that the increase in temperature induces EAI increase (tab. I) and a decrease in pH a decrease of erythrocyte aggregation (tab. II). It was found that at pH=3 and 5 erythrocytes are destroyed, and at pH=9 RBC clusters were formed. It may be concluded that RBC aggregate shape reflects intercellular interaction and its quantification may thus be another characteristic of RBC aggregation.

As demonstrated, a globular aggregate has an ASP near 1; the longer the aggregate, the smaller the ASP (fig. 6).

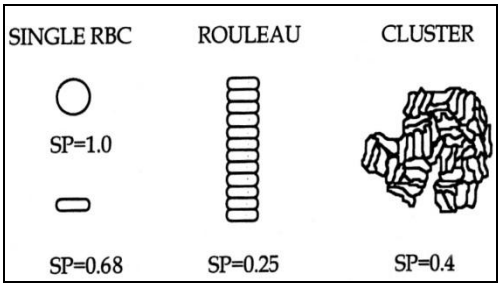

Fig. 6. Different aggregate shapes and corresponding ASP calculated according to equation no. 2 (1).

The theoretical model for rouleau aggregates (fig. 6) provides a useful reference for measuring deviations of RBC aggregate morphology from that of the rouleau structure, since normal blood is characterized by rouleau aggregates, and the formation of RBC clusters characterizes disease states (5).

Increased RBC aggregation was observed in various pathological states, such as diabetes and myocardial infarction, or following trauma.

Although erythrocyte aggregation phenomena were observed for a long time and several results were obtained, this phenomenon is not completely elucidated (6).

It is well known that erythrocyte aggregation is modified by cell deterioration in some physiological or pathological states (7).

Literature data show that the increase in temperature leads to the increase of erythrocyte aggregation. This was supported by Maeda (3) who demonstrated that the increase of temperature between 10°C and 40°C leads to the decrease of blood viscosity and of the stiffness of erythrocyte membrane responsible for the increase of erythrocyte aggregation.

The results on erythrocyte aggregation depending on pH are also satisfactory, being in agreement with Maeda's results (4) that evidence a RBC stiffness at low pH values and an increased aggregation at pH interval 6-9.

CONCLUSIONS

The computerized image analysis method to study the erythrocyte aggregation depending on temperature and pH could be successfully applied, having satisfactory results. We may conclude that the method has the following advantages:

- This method of image analysis is a direct method for measurement of erythrocyte aggregation;
- The Erythrocyte Aggregation Index (EAI) and the Aggregate Shape Parameter (ASP) values are quantitative;
- The method permits the comparison of the results obtained in different conditions (of temperature and pH);
- The method permits the comparison of the results obtained for different patients in a normal state of health or in diverse pathological states.

CONSERVATIVE TREATMENT OF DENTAL TRAUMA: CASE PRESENTATION-DIRECT ADHESIVE RESTORATION TECHNIQUES OF THE 4 UPPER INCISORS WITH DIFFERENT TYPES OF FRACTURES ON THE CORONAL LEVEL

Mihaela Cernușca Mițariu[1], Raluca Dragomir[2], B.Oprea[1], C.Țanțar[3], Alina Cristian[3], Cristina Dahm Tataru[1]

CONSERVATIVE TREATMENT OF DENTAL TRAUMA: CASE PRESENTATION-DIRECT ADHESIVE RESTORATION TECHNIQUES OF THE 4 UPPER INCISORS WITH DIFFERENT TYPES OF FRACTURES ON THE CORONAL LEVEL (Abstract): Dental trauma creates serious functional, aesthetic and psychological problems for the patient. The known developments in recent years in the area of materials and techniques related to direct composite resin restorations provide for the dentists direct conservative solutions that allow both morphology and aesthetic restoration and preservation of pulp vitality in many of the clinical situations encountered. A careful clinical examination and an accurate diagnosis (in terms of classification of the trauma) will allow the dentist to choose the most conservative therapeutic solution. We recommend the use of the diagnostic and therapeutic guidelines mentioned in the article. **Keywords:** DENTAL TRAUMA, CORONAL FRACTURE, DIRECTS COMPOSITE RESIN, CORONAL RECONSTRUCTION, and AESTHETICS.

Dental trauma is a fairly frequent condition among school age children and youth. Clinical studies have shown the most common causes of injuries are accidents during playing or sport events and rarely aggression. Moreover, dental traumas create functional, aesthetic and psychological problems for the patients. In these cases the challenge is doubled for the dentist who must restore the affected teeth both on functionally and esthetically. This requires a good understanding of direct restorative techniques including knowledge of color, form, adhesive protocol and laminating techniques.

The progress in recent years in the field of materials and techniques related to direct composite resin restorations provides advantageous solutions for the practitioner versus the indirect restorative therapy used before.

The advantages and disadvantages of dental restorations are as follows:

Direct composite resin restorations: *advantages*: available to any dentist, provides a conservative therapeutic approach, great aesthetic results, very good periodontal tolerance, easy to repair, affordable price; *disadvantages*: the technique is sensitive to any small errors and requires the dentist to have some experience, does not provide good results in case of intense tooth discoloration .

Indirect restorations with ceramic veneers: *advantages:* sufficiently conservative approach, great aesthetic results, great periodontal tolerance; *disadvantages:* minimum two sessions, greater "sacrifice" of tooth substance than with direct methods, several sources for error in technical and clinical stages (preparation, imprinting, and collage), difficult to repair, higher price.

Direct-indirect restorations with composite resins: *advantages:* conservative approach, great aesthetic results, very good periodontal tolerance, better polymerization, easy to repair, affordable price; *disadvantages:* requires technical skills, extended working time, instruments and additional equipment required (specific to dental laboratory).

The types of dental trauma that we can meet are extremely varied: bruises, subluxations, extrusions, lateral luxation, intrusions, avulsion, fractures of the enamel, dentin and enamel fractures, and fractures with coronal pulp chamber opening, crown-root fractures with or without affecting the pulp, root fractures, alveolar fractures.

Recently, a new classification of these injuries was published along with a therapeutic guide for every clinical situation. More information is available on the website of the International Association of Dental Traumatology (IADT):

www.dentaltraumaguide.org

CASE REPORT

A 16 years old male who had a skateboard accident resulting in multiple trauma of the upper incisor group.

Clinical examination revealed the following types of injuries: 1.2 -limited oblique fracture of the enamel at the level of mesio-incisal angle; 1.1- horizontal fracture at the mesial half of the crown, restricted to the enamel; 2.1 horizontal crown fracture of the enamel and dentin; 2.2 crown and root fracture with pulp chamber opening. (fig. 1, 2).

Fig. 1. Front view of the upper traumatized incisors group.

Fig. 2. Pulp exposed 2.2

In accordance with the recommendations of IADT, the treatment plan included three steps: step 1 – emergency treatment; step 2 – rehabilitation treatment; step 3 - clinical and radiological control at 6 months and 1 year for assessment of the

vitality of teeth 1.2, 1.1, 2.1.

During step 1, the treatment included: protection of fracture zones of teeth 1.2, 1.1, 2.1 using composite flow; performing endodontic treatment on tooth 2.2. Due to the destruction of the crown with great loss of tooth substance, this tooth requires the use of a pivot root during the crown restoration stage. Therefore, pulp ablation was performed in this stage, although the literature and treatment guidelines recommend only pulpohtomy (fig. 3, 4); contention tray was made for the patient to wear 7-10 days until the relief of the acute symptoms (fig. 5).

Fig. 3. Checkup of the endo treatment 2.2

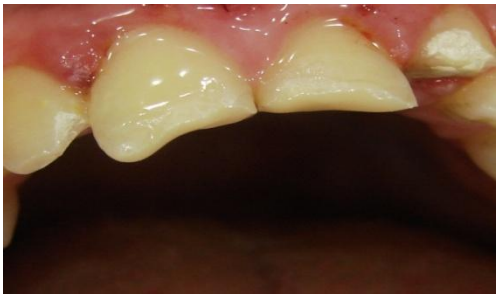

Fig. 4. The clinical aspect after endodontic treatment of tooth 2.2 and sealing the fracture zones in teeth 1.1 and 2.1 with composite flow.

Fortunately, the patient had just completed orthodontic treatment and the orthodontic department was able to provide us with the case study and cast models that have been used to make both the contention tray and the silicon guide during the second restorative stage (fig. 6, 7).

Fig. 5, 6. Mouth guards. Study models.

Fig. 7. Checking the correct positioning of the silicon guide.

Anti-inflammatory and analgesic medication was prescribed.

Second stage of treatment started 10 days later. All four incisors were restored. According to the IADT guidelines our treatment plan included: a silicon guide to

achieve the same shape and size of the incisors. (In order to make this silicon guide we used the casts from the orthodontic department); direct composite resin restorations to the teeth 1.2, 1.1, 2.1 presenting fractures of the enamel and enamel plus dentin areas. Mouth guards protected the teeth during the acute inflammatory period.

The restoration phase involved the specific stages of the adhesive technique:

1. dental surface preparation for collage (beveling the margins, Arkansas Type stones finishing, professional brushing);

2. adhesive stage- IV generation adhesive was used, in three steps: etching - primer adhesive;

3. direct composite resin stratification according to aesthetic principles using composite for each type of restored tissue: dentin, enamel, translucent (fig. 8, 9);

4. finishing and polishing

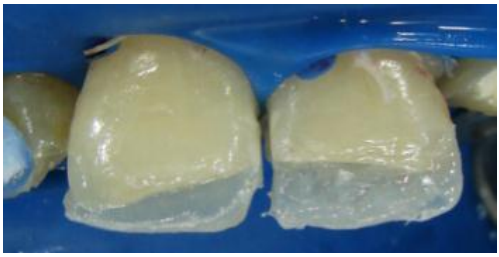

Fig. 8. Palatal wall view- translucent type composite.

Fig. 9. Intermediate phase during the restoration of tooth 1.1

A fiberglass root pivot was used for tooth 2.2 and the tooth crown was restored by direct stratification technique. The loss of substance in tooth 2.2 was at the gingival margin on the palatal side. This required an additional intervention using the electro cautery to highlight the extent of the fracture and achieve appropriate restoration at this level. 1.1, 2.1 were also restored using composite (fig. 10, 11, 12). Check-ups at one and two and a half years later showed satisfactory aesthetical and functional outcomes (fig. 13, 14).

Fig. 10., 11. Buccal and palatal view at the end of the restoration

Fig. 12 Final appearance after completing the restoration of all four upper incisors.

Fig. 13. Clinical aspect 14 months later.

Fig. 14. Follow-up 30 months later.

CONCLUSIONS

Regarding our case and the existing theoretical support, for most dental trauma, current conservative therapeutic solutions allow rapid recovery of the patient and satisfactory aesthetical and functional outcomes.

A careful clinical examination and accurate diagnosis (in terms of trauma classification) allow the clinician to choose the most conservative therapeutic solution. We recommend the use of guidelines for diagnosis and therapy listed above.

The practical application reported in this study confirms the previous studies related to restorative treatment of dental trauma through direct restorative technique. Furthermore, our results showed that implementation of this method for restorative treatments solve the aesthetic and functional problems of a trauma especially in case of the frontal teeth.

Improvement in the quality of materials used for direct restorations and their associated techniques create conditions for the clinician to act quickly and effectively avoiding the indirect restorative solutions (prosthetic), which are more expensive and require longer time.

The study can be a useful tool for researchers and practitioners keen to apply this technique in patients with dental trauma.

THE MRI FINE EVALUATION OF CERVICAL LYMPHADENOPATHIES AND ASSOCIATED ORAL CAVITY PATHOLOGICAL CONDITIONS (Abstract): The **aim** of this paper is to point out the value of MRI in diagnostic assessment of cervical lymphadenopathies and associated oral cavity pathological conditions. We used a statistic retrospective method to evaluate the results obtained after MRI examinations of 64 patients diagnosed with oral cavity pathology and cervical lymphadenopathies. In all cases the MRI exams detected the presence of cervical lymphadenopathies, their topoanatomic sites and oral cavity pathological entities that produced them. Due to fine characterization abilities by internal signal variation, MRI is the method of choice in daily practice for diagnosing, evaluation and staging of oral cavity pathology and cervical lymphadenopathies. Due to fine capacities of detecting internal signal variations in soft tissues or visceral parenchyma, MRI has high abilities in diagnostic assessment of oral cavity pathologies being a daily method of choice for diagnosing, evaluation and staging, with great value in any morbid entity. **Keywords:** CERVICAL LYMPHADENOPATHIES, ORAL CAVITY PATHOLOGY, MRI.

Aroused, as a general rule, by infectious lymphatic spread or by granulomatous or tumoral infiltration, cervical lymph-adenopathies are common marks, in daily practice, for diagnosing, evaluation and staging of oral cavity pathology (1).

Since cervical lymphadenopathies are very close related to oral cavity pathology, their presences affect the treatment and in case of malignancy reduce the 5-year survival following the rule of 50%. In a case of oral cavity squamous cell carcinoma the presence of a single cervical lymphadenopathy reduces the 5-year survival by 50%. If cervical lymph-adenopathies are bilateral, 5-year survival is reduced by another 50%. If there is clinically determined cervical lymph-adenopathy fixation or imaging data of extranodal extension expected survival goes down yet another 50% (2, 3).

In fact the clinician and the radiologist must work together as a team in staging oral cavity pathological entities since combined data can gain an 85% diagnostic accuracy (3).

Detecting internal signal variations MRI has high abilities in diagnostic assessment of oral cavity pathologies together with fine staging and evaluation of cervical lymphatic nodes spread (3).

MRI examination of cervical lymph-adenopathies can accurately detect the morphologic and volume changes from the local lymph nodes as a common result of any related anatomic pathologies (3).

The aim of this paper is to point out the value of MRI in cervical lymph-adenopathies examination and to underline the ability of this method, in daily practice for diagnosing, evaluation and staging of oral cavity pathology.

MATERIAL AND METHODS

MRI examinations were performed in cervical lymphadenopathies of 64 patients with oral cavity pathology clinically and biologically assessed and in cases of malignant diseases even with histo-pathological attestation.

The patients were MRI examined at Clinical Image Medical Imaging Center Timisoara using a 1.5 T Siemens unit and a dedicated investigation protocol. The MRI images were achieved as multiplanar SPIN-ECO in T1-wheighted acquisition with fine anatomical details and in T2 or Proton Density acquisition with great value in pathological changes detection. Fast imaging techniques as fast spin-eco and gradient - eco were sequences obtained very rapidly used in pre and postcontrast MRI evaluations. STIR - short tau inversion recovery - and DIFFUSION are very sensible techniques used for imaging subtle lesions detection (4).

The morphologic data: diameters, shape, contour, the presence or absence of central necrosis or cystic degeneration and extra capsular cervical lymph node extension are the MRI used diagnostic criteria of cervical lymphadenopathies (4).

The size criteria used depends on cervical lymph nodes location in one of the seven levels that they are anatomically classified. Level I nodes are the submental and submandibular nodes. Level II, III and IV are the nodes in the internal jugular chain, with level II nodes located from the base of the skull to the hyoid bone, level III nodes located between the hyoid bone and cricoid cartilage and level IV nodes located below the cricoid cartilage. Level V nodes are posterior to the sternocleidomastoid muscle. Level VI nodes are in the deep visceral chain and level VII nodes are in the superior mediastinum. Level II-VII nodes are considered pathologic in size if they are greater than 1 cm. Level I and the jugulo-digastric nodes are considered pathologic in size if they are greater than 1, 5 cm (5).

We used for malignant Hodgkin lymfoma RYE histologic classification and for malignant Non-Hodgkin lymphoma Working Group histological classification with Rappaport terminology equivalents. For precise evaluation of lymphatic nodal spread in malignant lymfoma we used Ann Arbor staging criteria (1).

In cases of oral cavity malignancy we used TNM classification in order to precise imaging tumoral, lymphatic nodes and metastasis staging.

RESULTS AND DISCUSSION

We diagnostic assessed cervical lymph-adenopathies according to size and architecture imaging criteria and we found in almost all cases nodal diameters between 1 and 3 cm corresponding to TNM stage NI.

In a case of malignant Hodgkin lymphoma (fig. 1) we detect and characterized

a group of cervical lymphadenopathies surrounding left carotid artery and adjacent vessels and muscles, with extra capsular spread in regional fatty tissue, as a mass of 6.7/2.4/4.4 cm in so termed carotid fixation.

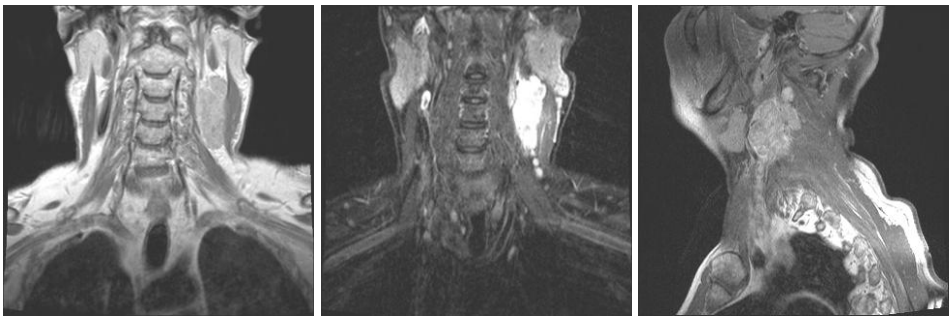

Fig 1. MRI exam of a patient with malignant Hodgkin lymphoma assessed a group of left cervical lymphadenopathies with carotid fixation

MRI cervical lymphadenopathy exam detected 22 cases of malignant cervical lymphadenopathies in patients with malignant lymphoma or oral cavity malignant tumors and 42 cases of reactive lymphadenopathies due to local inflammatory conditions induced by infectious lymphatic viral or microbial spread.

TABLE I

The oral cavity pathology associated with cervical lymphadenopathy

Oral cavity pathology	Number of cases
Malignant lymphadenopathies:	**22**
-carcinoma of the oropharynx	3
-carcinoma of the floor the mouth	3
-carcinoma of the salivary glands	2
-carcinoma of the tongue	2
-malignant Hodgkin lymphoma	
-mixt celularity	2
-nodular sclerosis	3
-limphocitic depletion	1
-malignant non - Hodgkin lymphoma	
-small grade of malignity	2
-intermediate grade of malignity	4
Reactive lymphadenopathies:	**42**
-viral parotidites	8
-tonsilites	14
-vestibular abcesses	8
-acute pharingites	10
-citomegalic inclusion disease	2

From 22 cases of malignant lymphadenopathies, 12 were latero-cervical forms of malignant lymphoma clinically, biologically and histopathological assessed at Hema-

tolology Clinic Timisoara and MRI evaluated at Clinical Image Medical Imaging Center (tab. I).

MRI-scan evaluated the extent of latero-cervical lymphadenopathies in 6 cases of malignant Hodgkin lymphoma: 2 in stage IIA and 4 in stage IIB and in 6 cases of malignant non - Hodgkin lymphoma all in stage IIA.

We evaluated by MRI 10 cases of oral cavity malignant tumors with lymphatic spread cervical lymphadenopathy clinically, biologically and histo-pathological assessed at Clinic of Cranio-Maxilo-Facial Surgery, Timisoara.

In the 3 cases of oropharingeal carcinoma we characterized aT2N1M0 palatine left tonsil localization and a T3N1M0 and a T4N1M base of tongue carcinoma (fig. 2, 3).

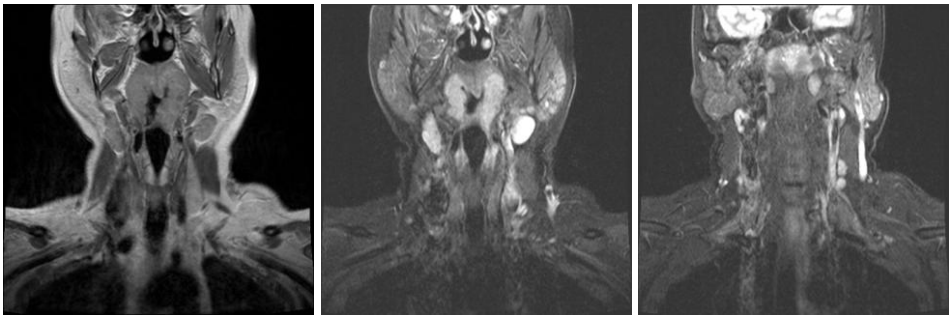

Fig. 2. A case of T2N1M0 palatine left tonsil carcinoma MRI clearly delineated and evaluated together with associated cervical lymphadenopathies

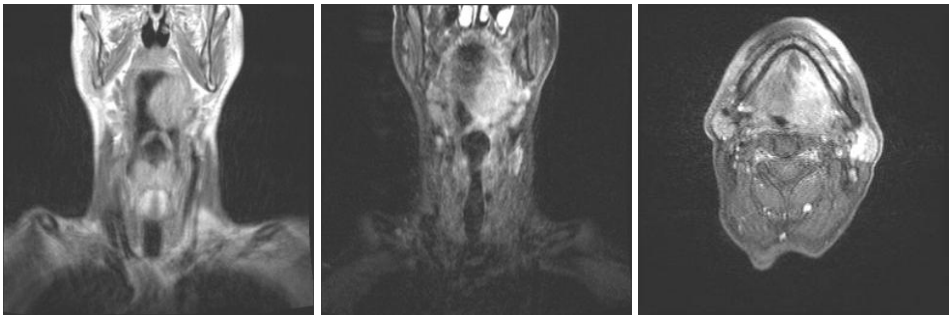

Fig. 3. MRI evaluation of a T3 left base of tongue carcinoma with N1 cervical lymphadenopathies

We detected 2 cases with T2N1M0 carcinoma of the floor the mouth and a T3N1M0 carcinoma with the same localization. MRI salivary glands evaluation revealed 2 cases of parotid gland carcinoma assessed as T2N1M0 and T3N1M0. In 2 cases we detected and evaluated by MRI-scan T2N1M0 carcinomas of the tongue.

We proceeded to MRI exam in 42 cases of nonmalignant oral cavity pathology at clinician indications to exclude tumoral pathology with fine characterization of inflammatory visceral changes and reactive lymphadenopathies detection. The vast majority of patients reclaimed clinical symptoms of viral or microbial infection together with latero-cervical mass or asymmetry due to cervical lymph-adenopathies.

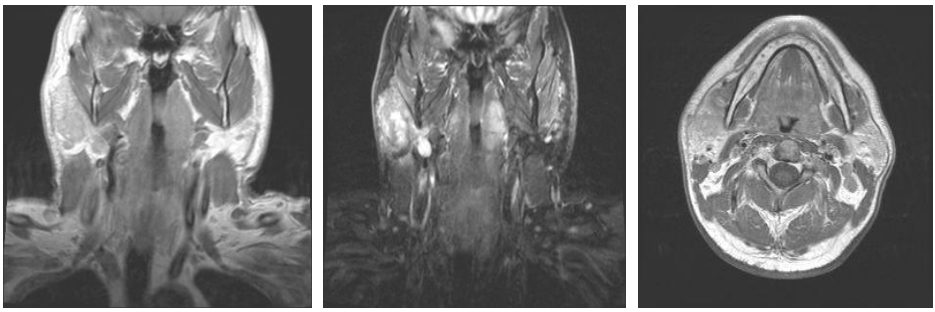

Fig. 4. MRI exam of a T2 right parotid gland carcinoma with N1 cervical lymphadenopathies

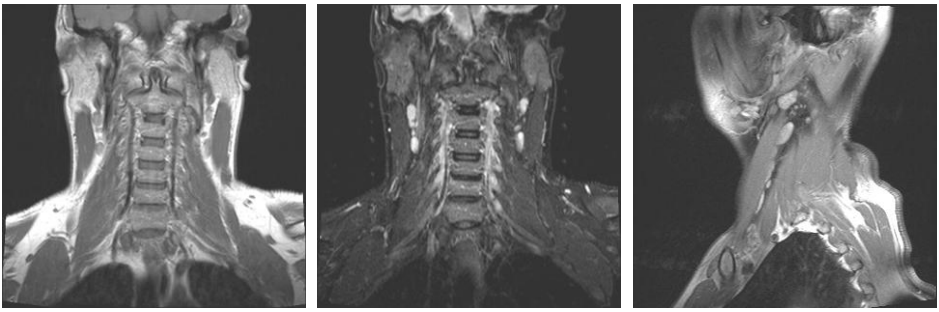

Fig. 5. MRI of a patient with latero-cervical asymmetry due to level III reactive internal jugular chain lymphadenopathies with greater transverse diameter on right side caused by microbial infection spread from a homolateral vestibular abcess

CONCLUSIONS

The size and architecture criteria for cervical lymphadenopathies imaging diagnostic assessment are the best used by MRI to detect, stage and topographic localize their pathological involvement.

MRI has gained a large known indication in malignant lymphoma for precise identification of lymphatic nodal spread, staging and accurately pre and post treatment evaluations.

USE OF BLOOD MARKERS IN EARLY DIAGNOSIS OF OXIDATIVE STRESS IN AGE RELATED MACULAR DEGENERATION (Abstract): Age related macular degeneration (AMD) is the most frequent cause of irreversible blindness in the elderly population, affecting approximately 30-50 million people around the world. **Aim**: to establish the role of oxidative stress in retinal structural lesions. **Materials and methods**: It is a case-control study that included 19 patients diagnosed with AMD. Depending on the severity of the diagnosis, patients were divided into 3 groups: group 1 - mild AMD, group 2 – moderate, atrophic AMD, group 3 – severe, neovascular AMD. They were followed by assessment of visual acuity, optical coherence tomography (OCT) and oxidative stress markers like superoxide-dismutase (SOD), thiobarbituric acid reactive substances (TBARS) and inflammatory marker – C-reactive protein (CRP). **Results**: Risk factors involved in patients with AMD are arterial hypertension, smoking, hyperlipidemia and diet poor in antioxidants, as revealed in the questionnaire. Retinal thickness assessed by optical coherence tomography showed that values in patients with severity level 2 is within normal limits, while in patients with severity level 3, these values are significantly increased due to macular edema. The mean values of SOD, TBARS and CRP in the studied group were significantly higher compared to controls, being higher in group severity level 3. **Conclusion**s: This study shows the role of oxidative stress and inflammation in retinal structural lesions in AMD and the importance of blood markers in early detection of oxidative stress and thus of retinal lesions in this disease. **Keywords**: AGE RELATED MACULAR DEGENERATION, OXIDATIVE STRESS, RETINAL THICKNESS.

Age-related macular degeneration (AMD) is the most common cause of irreversible blindness in the elderly population, affecting approximately 30-50 million people (1). AMD consists of degenerative and inflammatory lesions of the macular region, occurring in a previously normal eye and resulting in deterioration of central vision and macular function (2). The disease begins as a non-neovascular or dry stage, which can progress to geographic atrophy or macular neovascularisation. Recently, the research has focused on the risk factors that could be involved in the development of AMD, such as oxidative stress, inflammation and phototoxic stress (3, 4).

The aim of this study is to establish the role of oxidative stress in retinal structural

and functional changes in AMD. Also, it is meant to highlight the role of blood markers in early diagnosis of oxidative stress and consequently in early identification of retinal lesions.

MATERIAL AND METHODS

This is a case-control study that included a group of 19 patients diagnosed with AMD, selected from the „N. Oblu Hospital" in Iaşi, and two control groups, one with younger controls and another with controls with similar ages as the cases. Patients with systemic and ocular diseases that could increase oxidative stress, such as diabetes, inflammatory and infectious diseases, and vascular occlusions were excluded.

According to the law of patients' rights, they signed an informed consent and completed a questionnaire concerning risk factors, associated diseases, living conditions, subjective complaints and an Amsler grid. A score was calculated for each patient.

During a follow-up period for a median of 8 months, we recorded the visual acuity, anterior pole biomicroscopy, posterior pole appearance (Volk 78 D lens), Optical Coherence Tomography (OCT) and laboratory tests. As regards the laboratory tests, we followed the oxidative stress markers such as thiobarbituric acid reactive substances (TBARS), antioxidant enzymes - superoxide dismutase (SOD), and markers of inflammation - C-reactive protein (CRP).

Depending on the severity of the diagnosis, patients were divided into 3 groups according to the classification of "Age-Related Eye Disease Study" (AREDS) of the U.S. National Eye Institute: group 1 - mild AMD, group 2 – moderate, atrophic AMD, group 3 - severe neovascular AMD. According to the appearance of the posterior pole and the OCT results, we maintained the same classes. In the study group there were included only patients with severity level 2 and 3. The retinal thickness and retinal nerve fiber layer were measured with Spectral OCT OPTOPOL in 9 quadrants.

SOD activity was determined by xanthine oxidase method, TBARS were quantified by colorimetric method and CRP measurement was made by imun-turbidometry with calibrator.

The statistical analysis (performed with the Statistical Programme 7.0), was intended to highlight significant correlations between the severity of the diagnosis and results of the OCT, visual acuity and results of the blood tests. The statistical comparison was made with "Difference tests" from the sub-set of descriptive statistic programs, being significant those differences which stood at a safe threshold of 95% ($p < 0.05$).

RESULTS

We investigated a group of 19 subjects, 8 males (42.11%) and 11 women (57.89%) with a mean age of 72.47 ± 7.74 years (59 to 88). The first control group (older group) included 11 subjects (3 men and 8 women), with ages ranging between 60 and 85 years. We used the second control group (young group), which comprised of 40 subjects (11 men and 29 women), aged between 28 and 60 years, in order to compare the laboratory results.

We evaluated the risk factors in the study group and in the control group and we showed that there was a higher frequency of arterial hypertension (HTA), smoking, lack of antioxidants and UV exposure in the study group (fig. 1).

There were enrolled 16 patients with ne-

ovascular AMD, severity level 3, and 3 patients with dry form, severity level 2. We present the average retinal thickness, depending on the severity of diagnosis (tab. I).

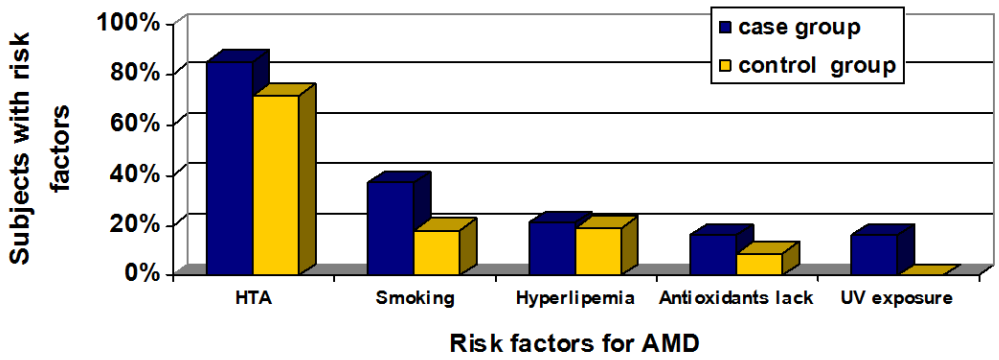

Fig. 1. Risk factors in the study and control groups

There were enrolled 16 patients with neovascular AMD, severity level 3, and 3 patients with dry form, severity level 2. We present the average retinal thickness, depending on the severity of diagnosis (tab. I).

TABLE I

Indicators of the average retinal thickness in the two severity groups

	Severity level 3 – retinal thickness			**Severity level 2 – retinal thickness**		
Quadrant	**Average** (μ)	**Minimum** (μ)	**Maximum** (μ)	**Average** (μ)	**Minimum** (μ)	**Maximum** (μ)
Quadrant 1	381.62	164.00	620.00	241.33	173.00	307.00
Quadrant 2	372.68	224.00	547.00	263.33	205.00	327.00
Quadrant 3	357.00	180.00	623.00	245.33	198.00	323.00
Quadrant 4	377.81	257.00	549.00	265.66	247.00	302.00
Quadrant 5	358.62	187.00	571.00	306.66	247.00	350.00
Quadrant 6	307.06	185.00	444.00	228.33	214.00	252.00
Quadrant 7	317.37	156.00	592.00	226.00	158.00	297.00
Quadrant 8	318.87	210.00	472.00	244.66	225.00	263.00
Quadrant 9	340.75	266.00	481.00	280.33	246.00	318.00
Average	347.27	228.88	495.00	257.46	231.12	295.50

In patients with the neovascular form, mean retinal thickness was 347.27 μ, signifying the presence of macular edema (over 340μ), with a maximum of 495μ.

In patients with dry form, mean retinal thickness was 257.47μ, falling within the normal range. Next we evaluated the retinal nerve fiber layer thickness, depending on the severity of diagnosis. The average thickness was much lower than normal both in severity level 2 group and severity level 3 group.

The average visual acuity is significantly higher in subjects with a diagnosis of severity level 2 (0.67) compared with 0.25 in those with level 3 severity (p = 0.005). The score was significantly higher in group severity 3 (39) compared to group severity 2 (28).

Depending on the aspect of the posterior pole and the OCT results, the average thickness of the retina is significantly higher in cases with severity level 3 compared to those with severity level 2 (fig. 2).

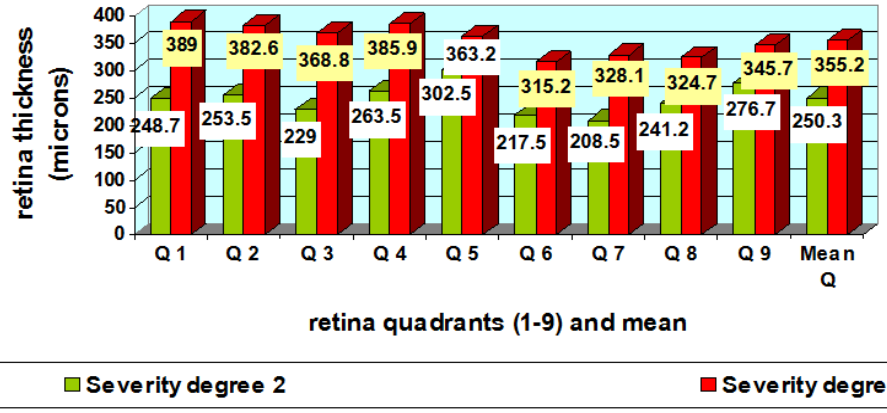

Fig. 2. The average thickness depending of the OCT results

We determined the levels of SOD, TBARS and CRP in the study group, older control group, and in the younger control group. To highlight the differences between groups it was used the t Student test, appreciating as significant those with p <0.05.

TABLE II

The mean values of laboratory tests

Groups	Number	SOD (U/ml)	TBARS (nmols/ml)	CRP (mg/dl)
Study group	19	331.8	4.6	3.2
Older control group	11	269.5	3.9	1.5
Younger control group	40	196.1	3.1	0.9

Comparing the mean values in the three groups, we found that the mean values of SOD, TBARS and CRP were significantly higher in the study group compared to con-

trols; the mean values of SOD and TBARS were significantly higher in the older control group compared to younger control group (tab. II). We also found that the values were higher in the group with severity 3 diagnosis, compared to severity 2 (fig. 3, 4).

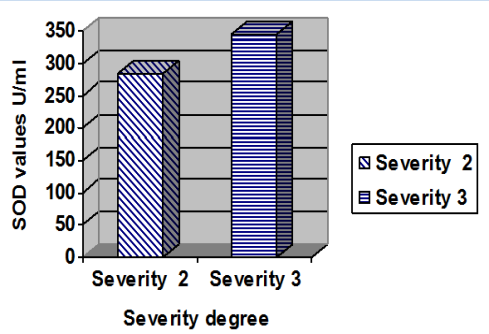

Fig. 3. The mean values of SOD in group severity 3 and 2

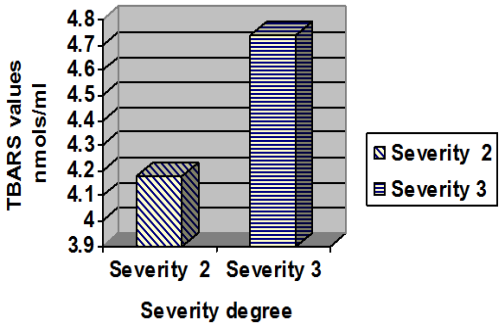

Fig. 4. The mean values of TBARS in group severity 3 and 2

DISCUSSION

We found that AMD correlated with certain risk factors, like arterial hypertension, smoking, hyperlipidemia and low antioxidants diet, which is consistent with the literature (1, 2).

Comparing the mean values of retinal thickness depending on the severity of diagnosis, we found an average value of 347.27 μ in the group of patients with severity level 3, significantly higher ($p = 0.02$) compared to those with severity level 2 (257.47 μ). The average thickness of the nerve fibers layer is 32.29 μ (ranging between 16.78 and 49.78 μ), being much lower than normal (90μ). It can be noticed that in severity level 2 group the average thickness of the retina is normal in all quadrants, while in those with severity level 3, it is above the upper limit in 5 of the 9 quadrants. These data are consistent with other studies published in the literature. Kolb (5) studied 75 eyes with neovascular AMD, treated with intravitrean drugs against vascular endothelial growth factor (anti-VEGF). Mean retinal thickness was higher than normal and its reduction was observed after treatment. Garas (6) has shown that AMD affects the macular thickness parameters in eyes without glaucoma.

We showed an increase in antioxidant enzymes (SOD) in the study group (331.8 U/ml) compared with the two control groups (young - 196.1 U/ml and older - 296.5 U/ml). SOD is one of the main antioxidant systems, that increased by a feedback mechanism, trying to keep the balance between antioxidants and free radicals. Dong (7) hypothesized that SOD protects retinal cells from oxidative stress. The results are consistent with the study by Imamura (8) who showed that the retinas of mice deficient in SOD1 had several key elements of human AMD. Kasahara (9) showed that homozygous mice deficient in SOD2 present morphological changes in the RPE and Bruch membrane and accumulation of oxidized proteins. Jia (10) found elevated levels of SOD and malondialdehide (MDA) in patients with AMD as a compensatory response. Shen (11) showed an increase in SOD activity compared to

the control group, along with a decrease in antioxidants. In the POLA study (12) the authors showed that another antioxidant enzyme, glutationperoxidase, increases in patients with AMD.

In this study we evaluated TBARS values, one of the earliest markers of oxidative stress. However, this marker has been less studied in relation to AMD. The mean value of TBARS in the study group was significantly higher (4.6 nmols/ml) than that in the control groups (young control group: 3.0 nmols/ml and older control group: 3.9 nmols/ml), which supports the idea that oxidative stress is involved in the etiopathogenesis of this disease. The mean SOD and TBARS values were significantly higher in elder control group compared with younger control group (SOD: 269.5 vs. 196.05 U/ml, TBARS: 3.9 *vs.* 3.0 nmols/ml). The mean values of laboratory tests were significantly higher in the group of subjects with severity level 3 compared to severity level 2.

To demonstrate the role of inflammation in AMD, we compared the mean values of CRP. Mean CRP was significantly higher in the study group (3.2 mg/dl) compared with controls (1.5 mg/dl). These data are consistent with other studies, showing an increased value of this marker (13, 14, 15, 16). The Rotterdam Study (15) showed that elevated CRP levels at baseline were associated with progression of AMD. Our study confirmed that elevated CRP levels were associated particularly with advanced form of AMD. Seddon (17) showed that CRP values were higher in subjects with severe maculopathies.

CONCLUSIONS

This research highlights the role of oxidative stress and inflammation in retinal structural lesions of age-related macular degeneration and the role of antioxidant enzymes in the early detection of oxidative stress. Risk factors involved in patients with age-related macular degeneration are arterial hypertension, smoking, hyperlipidemia and diet poor in antioxidants, as revealed in the questionnaire. Retinal thickness assessed by optical coherence tomography showed that values in patients with severity level 2 is within normal limits, while in patients with severity level 3, these values are significantly increased due to macular edema. Oxidative stress and inflammatory markers are elevated in the study group compared with control groups. This demonstrates that oxidative stress in relation to inflammatory stress is involved in the pathogenesis of age-related macular degeneration.

PERIPROSTHETIC FEMORAL FRACTURES – EVALUATION OF RISK FACTORS

Liliana Savin, C. Barbăroşie, P. Botez
University of Medicine and Pharmacy „Grigore T. Popa"- Iasi
School of Medicine
Discipline of Orthopedics-Traumatology

PERIPROSTHETIC FEMORAL FRACTURES – EVALUATION OF RISK FACTORS (Abstract): Endoprosthetic hip arthroplasty is a surgical intervention that significantly improves the quality of the patient's life, with excellent long term results, but with an increased risk of major complications. One such complication is the periprosthetic femoral fracture, which may occur in both young and old patients due to several risk factors typical to the elderly (osteoporosis, fall risk), cementless press-fit implants, implant loosening, and revision arthroplasty. **Material and methods:** This study tries to evaluate the risk factors for periprosthetic femoral fractures treated at the Orthopedics and Trauma Department of the Iaşi Rehabilitation Hospital. Retrospective evaluations were conducted on 3454 patients with primary hip arthroplasty and 167 patients with revision hip arthroplasty, the surgical procedures being performed between January 1994 and March 2012. The study was conducted on 47 patients (17 males and 30 females, mean age 68 years) with periprosthetic fracture. **Results:** The incidence of periprosthetic femoral fractures in primary arthroplasty group was 0.89% (0.63% intraoperative and 0.26% postoperative), with a considerably higher incidence for cementless implants (81.39%), and 9.58% in revision arthroplasty group (8.38% intraoperative and 1.19% postoperative). Vancouver type B was the most frequent, both in operative and postoperative revision arthroplasty and in postoperative primary arthroplasty. 88% of the fractures were surgically treated, with a satisfactory postoperative course both in early and long-term follow-up. **Conclusions:** Periprosthetic femoral fractures result in increased morbidity and mortality rate, are difficult to treat, and require complex therapeutic strategies depending on risk factors, fracture type, bone stock, and implant stability. **Key words:** HIP ARTHROPLASTY, PERIPROSTHETIC FRACTURES, REVISION ARTHROPLASTY

The improvement in lifestyle entailed the necessity to improve the quality of patient's life up to an advanced age by means of pain relief and a normal functioning of the hip joint, two goals achieved by endoprosthetic hip arthroplasty. There is an increase in the number of postoperative complications directly proportional to the number of arthroplasties performed given the extension of its indications in both aged and young patients suffering from congenital dysplasia or aseptic necrosis of femoral head. One of the major complications is periprosthetic femoral fracture, with an increased incidence in both age groups, due to the significant risk of osteoporosis in the elderly, high-energy trauma in the young patients who are physically very active, and to a rise in the number of revision arthroplasties (1).

The risk factors for these fractures share

a common feature, namely a poor bone quality and reduced mechanical strength. An etiological classification of these risk factors as local and systemic is generally useful, although they often coexist.

Periprosthetic femoral fractures are more frequent in patients suffering from rheumatoid polyarthritis and severe osteoporosis, but may also occur against the background of other diseases such as osteomalacia, Paget's disease, osteogenesis imperfect, thalassemia, and some neuromuscular disorders such as poliomyelitis or Parkinsonism. Local risk factors for operative fractures include the use of cementless press-fit femoral components, proximal femur deformity, and revision arthroplasty.

Local risk factors for postoperative fractures are osteoporosis, periprosthetic osteolysis, femoral component loosening (2), femoral component malalignment, cortical perforation undetected during surgery, and infection. The most frequent cause of periprosthetic femoral fracture is a minor trauma caused by a same height fall. Adolphson et al. have reported a low-energy trauma in 88% of the fractures studied, (28 out of 35) (3). Cooke and Newman have reported a major trauma only in 8% (6 out of 75) of the cases (4). The incidence reported for periprosthetic femoral fractures is of 0.1% - 7.8%, depending on the reported series (1, 5, 6, and 7). Berry noted an incidence of postoperative periprosthetic femoral fractures of <1% after primary arthroplasty and of >7.8% after revision arthroplasty (5). Mayo Clinic reported an incidence of 0.6% in cemented total hip arthroplasty and 0.4% in the cementless ones (6). Lindahl et al. reported an incidence of 0.4% after primary arthroplasty and 2.1% after revision arthroplasty (1). In a study of 1442 cemented primary arthroplasties with a risk factor of 2.5%, Löwenhielm et al. reported an annual incidence between 0% and 1.2% (7). During primary arthroplasties, intraoperative periprosthetic fractures have been estimated to approximately 1% of the cemented stems (8, 9, 10) and between 3% and 20% of the cementless ones (11, 12, 13). During revision arthroplasties, periprosthetic fractures seem to follow similar patterns, but their occurrence is more frequent, the incidence of operative fractures being of 6.3% (14) for the cemented cases and 17.6% for the cementless ones (15).

MATERIAL AND METHODS

The study was conducted on 3454 patients with primary endoprosthetic hip arthroplasty and 167 patients with revision arthroplasty admitted to the Orthopedics and Trauma Department of the Iaşi Rehabilitation Hospital between January 1994 and March 2012. The retrospective evaluation was done on 47 patients with periprosthetic fractures, 36 intraoperative and 11 postoperative. This study investigated the incidence of periprosthetic fractures in relation with various local and general risk factors, type of arthroplasty, pathology requiring the primary surgical intervention, demographic data (age and sex), and time of postoperative fracture.

Periprosthetic fractures were assessed based on standard radiographs and categorized according to the Vancouver Classification System. Operative periprosthetic femoral fractures are divided into three types based on fracture location: A – proximal metaphyseal without diaphyseal impaction; B – diaphyseal; C – diaphyseal-metaphyseal distal fracture, further subdivided into three subtypes: 1). cortical perforation, 2). non-displaced fracture, and 3). displaced unstable fracture.

Postoperative periprosthetic fractures are classified into:

- A - trochanteric region with A(G) - Greater trochanter and A(L) – Lesser trochanter;
- B – around or distal to the stem, further divided into: B1 (stable prosthesis), B2 (unstable prosthesis), B3 (bone stock inadequate);
- C – well distal to the stem tip.

Other classification systems were used to assess the stability of the cemented and cementless femoral stems. Stability of cemented stem was evaluated according to the classification criteria defined by Harris et al. (16), while Engh and Massin (17) classification was used to assess stability of the cementless stem. According to these classifications, *loosening* is defined as stem displacement, visible on radiograph plates by means of either radiotransparent lines between the cement or the femoral stem and bone, or the presence of cement fracture, and/or the presence of a radiotransparent area which comprises 50 to 100% of the bone-cement gap size.

RESULTS

The prevalence of periprosthetic fractures was 1.29% of the total number of primary and revision arthroplasties, with an incidence of 0.89% (31 cases) in primary arthroplasty and 9.58% (16 cases) in revision arthroplasty. According to the time of occurrence, in primary arthroplasty there were 22 intraoperative (0.63%) and 9 postoperative periprosthetic fractures (0.26%). As to revision arthroplasty of the hip, 14 operative (8.38%) and 2 postoperative fractures (1.19%) were found. These results are in agreement with the statistical data reported in the literature (5).

The etiological assessment of hip arthroplasty showed degenerative pathology in 31 cases (65.95%), stage III-IV aseptic necrosis in 5 cases (10.63%), and femoral neck fracture in 11 cases (23.40%).

According to the type of implant used, periprosthetic fractures occurred in 37 total hip arthroplasties (THA) and in 10 hemiarthroplasties of which 4 bipolar and 6 cervocephalic (unipolar). The incidence of periprosthetic fractures was significantly higher in cementless (cless) arthroplasty – 81.39% (38 cases) compared with cemented (cem) arthroplasty– 18.7% (9 cases), as can be seen in the graphical representations below (fig. 1, 2).

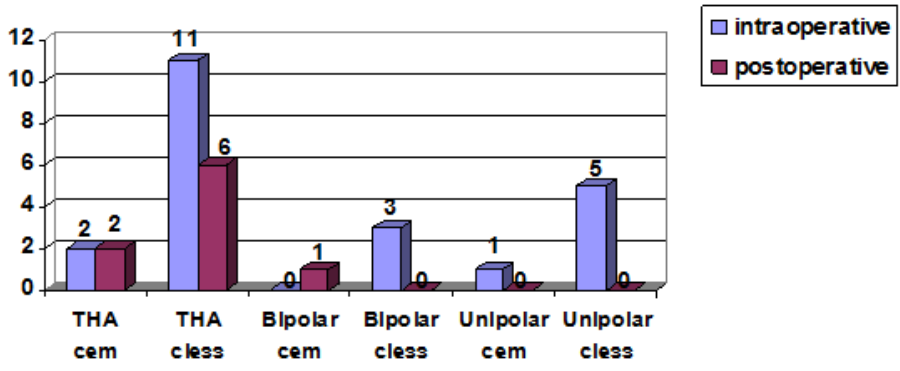

Fig. 1. Incidence of fractures in primary arthroplasty according to the implant type

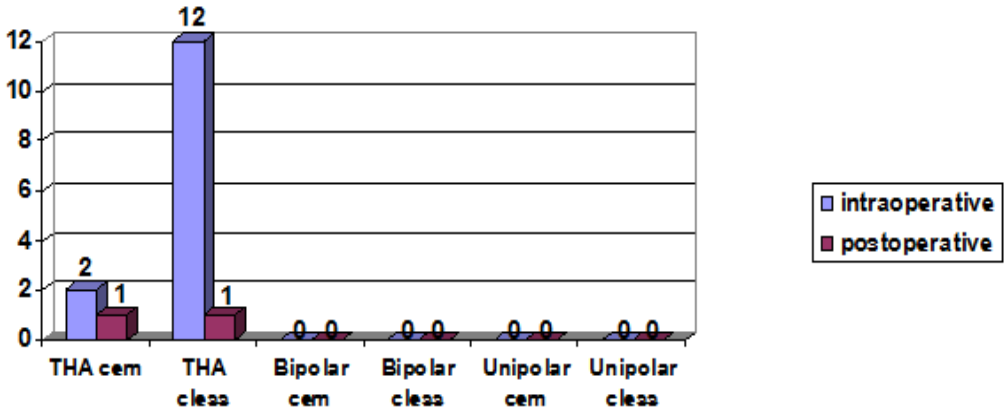

Fig. 2. Incidence of fractures in revision arthroplasty according to the implant type

The time of occurrence of postoperative periprosthetic fractures was: early in 5 cases (the first six weeks), 1-3 years in 3 cases, and after 6 years in 3 cases. In all these 13 cases fractures were caused by low-energy trauma, by same height falls.

In addition, the following associated risk factors have been monitored: osteoporosis in 19 cases (40.42%), rheumatoid polyarthritis in 5 cases, ankylosing spondylitis in 3 cases. Early or late postoperative periprosthetic fractures have the following local risk factors: cementless press-fit stems with cortical perforation undetected during surgery, osteolysis and loosening. Operative periprosthetic fractures occur as a result of press-fit femoral components, local osteoporosis, and brutal manipulation. In revision arthroplasty the most frequently met are osteolysis and loosening with a more or less severe associated cortical defect. Another cause is a specific infection (TB) (fig. 3).

Patients' mean age was 68 years (range 53 - 79 years) for postoperative fractures, 62 (range 40 – 82 eyars) for intraoperative fractures in primary arthroplasties, and 58 (40 - 67 years) in revision arthroplasties. Thirty patients (63.8%) were females.

Using the Vancouver Classification System the fractures were categorized as follows: 1). intraoperative in primary arthroplasties: 9 A2 fractures, 6 B1 fractures, 7 B2 fractures; 2). intraoperative in revision arthroplasties: 2 A2 fractures, 2 B2 fractures, 6 B3 fractures, and 1 C2 fracture; 3). postoperative in primary arthroplasties: 6 B1 fractures, 3 B2 fractures; and 4). postoperative in revision arthroplasties: 1 B3 fracture and 1 C fracture.

The therapeutical strategy depended on fracture type, time of fracture, implant and fracture stability, and bone stock. Consequently, 5 intraoperative B1 fractures were treated conservatively by forbidding leaning, 4 revision arthroplasties necessitated osteoplasty with structural allograft (25%), one revision arthroplasty required osteosynthesis with screwed plate, but most frequent was open reduction and fixation with metallic wires or Dahl Miles cables. The course was satisfactory in all cases, with consolidation and progressive regaining of articular mobility.

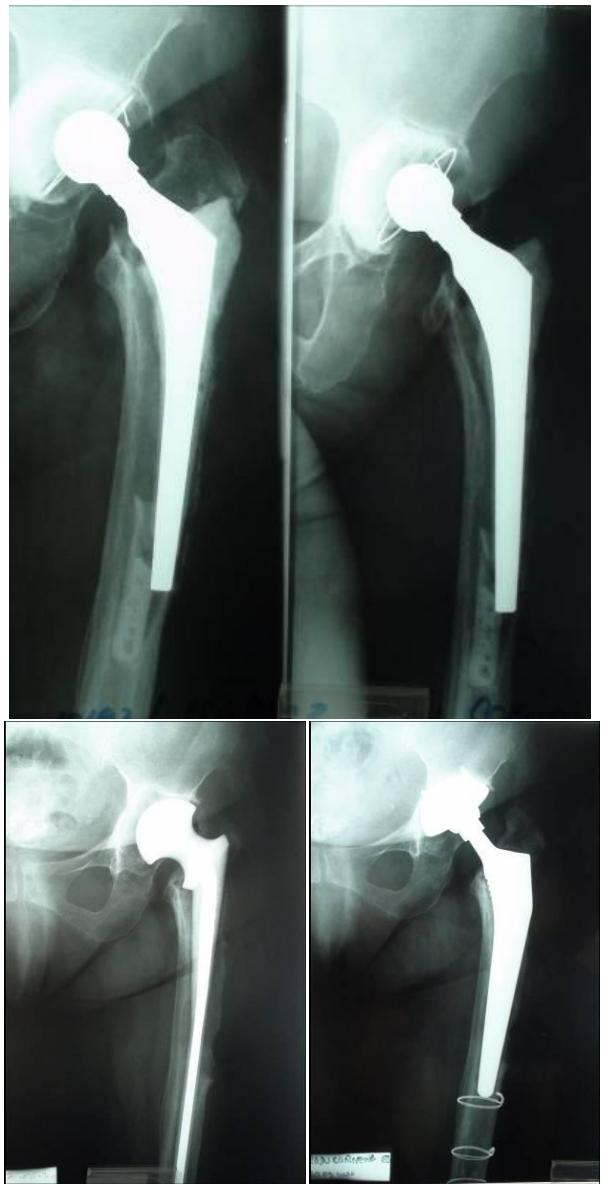

Fig. 3. Septic (specific) loosening; 1st step revision: acrylic spacer; 2nd step revision: uncemented total arthroplasty with intraoperative periprosthetic femoral fracture Vancouver B3.

DISCUSSION

The management of periprosthetic femoral fractures includes the identification of local and systemic risk factors, an accurate preoperative assessment, and an adequate therapeutical indication.

The systemic risk factors determine a decrease in bone quality and mechanical

strength and increase the likelihood of intra- and postoperative femoral fractures occurrence. Among these, the most frequent are postmenopausal and senile osteoporosis and rheumatic conditions (rheumatoid polyarthritis).

The local risk factors for intraoperative fractures include the use of cementless press-fit femoral components, proximal femur deformity, and revision surgery. The cementless femoral component may cause fracture as a result of overworking and additional forces distributed to the proximal femur during the press fit impaction. The deformities of the proximal femur, as can be seen in hip dysplasia, pseudoarthritis, and prior surgical interventions, may also increase the risk for intraoperative fracture. Revision arthroplasty has a higher incidence of intraoperative fracture than primary arthroplasty. During revision arthroplasty the femoral bone mass is often deficient due to multiple prior interventions or following infections or osteolysis. A narrowed cortical vein in relation to the medullar duct of the femur represents a risk factor in intraoperative fractures. Revision arthroplasty requires reconstruction with prostheses larger in diameter and length, often resulting in a higher intraoperative fracture rate due to excessive femoral hole and perforation.

The unrecognized cortical perforation during hip arthroplasty is an important risk factor in postoperative femoral fractures. Accidental perforation is most likely to occur during channel preparation and drilling. The impingement of femoral stem against the endosteal cortex may also increase the stress levels. This situation can occur as a result of the varus malalignment of femoral prosthesis and impingement in the lateral cortex.

Periprosthetic osteolysis is another local risk factor associated with postoperative fractures and it has become increasingly more frequent. The loosening of the femoral component is another significant local risk factor and it has been identified in 75% of the patients with postoperative periprosthetic femoral fractures in a study conducted by Bethea et al. (2). Duncan and Masri have reported loosening in 82 % of their cases (18).

CONCLUSIONS

Our study confirms the importance of risk factors assessment in periprosthetic femoral fractures in primary and revision hip arthroplasty, and points out the high risk of fracture when using cementless implants.

The main goal in the prevention of periprosthetic fractures is a rigorous preoperative planning in order to anticipate any potential trap or problem that may appear during surgery. Preparation is paramount in dealing with these problems. Meticulous history, rigorous clinical investigation (scars and articular rigidities which may require special techniques for surgical exposure and intraoperative manipulation of the limbs), as well as an accurate specific imaging examination with assessment of deformities, hip architecture and degree of osteoporosis are essential in the prevention of intraoperative fractures in primary arthroplasty.

In revision arthroplasties radiographic evaluation must focus on the degree of bone deficit, cortical vein discontinuity, and possible deformities.

Osteodensiometry scans and an adequate antiosteoporotic treatment are the

main means of preventing postoperative fractures.

The decision concerning the therapeutical strategy and surgical indications for periprosthetic femoral fractures is based on fracture level, patient's remaining bone stock, and stem stability. The objectives of periprosthetic fracture treatment include: restoring the anatomical alignment, recovery of the adequate bone stock, creation of a stable prosthesis, early mobilization of the patient, quick consolidation of the fracture, and the return to the original function prior to fracture.

2. Department of Pharmacology

POSTTRAUMATIC STRESS DISORDER: NEUROENDOCRINE AND PHARMACOTHERAPEUTIC APPROACH (Abstract): Posttraumatic stress disorder (PTSD) is represented by the development of characteristic symptoms, that appear following direct/indirect exposure to a traumatic event in which physical harm was threatened, witnessed or experienced. PTSD can also occur after the unexpected death of a family member or close friend, following a serious harm or threat of death or injury to a loved one, or in case of divorce or unemplyoement. It occurs in 1% - 4% of the population. As neuroendocrine pattern, PTSD is characterized by abnormal low cortisol levels and higher than normal epinephrine and norepinephrine levels. In chronique forms a total decrease of the hippocampal volume, was found, region of the brain involved in processing memories and in the memorization process. Symptoms are grouped in three main categories: re-experiencing the event, accompanied by anxiety, nightmares and flashbacks; persistent avoidance of any reminders of the event, feeling detached or estranged from others; persistent anxiety and/or physical reactivity. As treatment, besides various psychotherapy techniques, various classes of psychotropic drugs are used, such as morphine, antipsychotics, usual or atypical antidepressants, anticonvulsants, to reduce anxiety, avoidance, nightmares and hyperexcitability. **Key-words:** POSTTRAUMATIC STRESS DISORDER (PTSD), CORTISOL

DEFINITION AND HISTORY

Posttraumatic stress disorder is a severe anxiety disorder that may develop after exposure to any event those results in psychological trauma. The event involves the threat of death to oneself or to someone else or to one's own or someone else's physical, sexual, or psychological integrity, overwhelming the individual's ability to cope.

One of the first descriptions of PTSD was made by Herodotus, who described an Athenian soldier with no war injury, but who became blind after witnessing the death of a fellow soldier, during the Battle of Marathon.

In the early 1800's military medical practitioners diagnosed soldiers with "exhaustion" after the stress of battle. One-tenth of the mobilized Americans were hospitalized for mental problems, between 1942 and 1945, and after thirty-five days of uninterrupted combat, 98 % of them suffered psychiatric disturbances of various degrees (1).

Modern understanding of PTSD situates in the 1970s, especially as a result of expe-

riencing with US veterans of the Vietnam War. The term PTSD was adopted in the mid 1970s and recognized in 1980. Earlier terms used for PTSD are: stress syndrome, shell syndrome, battle fatigue, railway spine, traumatic war neurosis.

NEUROENDOCRINE ASPECTS

To react appropriately to danger, one must rapidly trigger a complex set of behavioral responses. The locus ceruleus, located in the dorsal pons has a crucial importance in nervous system responses to threat. Its broad connections with cortical structures – hippocampus, hypothalamus, amygdala and spinal cord involve locus ceruleus in affective, cognitive and motor responses to acute stress. Activation of locus ceruleus neurons stimulates norepinephrine secretion, modulating behavioral responses to accute stressors (2, 3).

Besides activation of noradrenergic system, exposure to acute stress determines neuroendocrine changes, modulated by the HPA axis. Studies revealed low cortisol levels in PTSD patients (war veterans, holocaust survivors, rape victims, individuals exposed to a natural disaster) when compared to controls (4, 5).

Several studies reported that in response to dexamethasone, individuals with PTSD show a more intense suppression of ACTH and cortisol release than normal controls (6,7). Some studies showed changes in hippocampal size (reduction of hippocampal size in PTSD subjects, compared to controls) and function, which may be an important feature of chronic PTSD (8).

Sometimes is difficult to establish which of the biological responses are uniquely associated with PTSD, and which may be included in the range of normal stress responses.

SIGNS AND SYMPTOMS

Symptoms of PTSD usually develop in the first three months after the trauma, but sometimes they may not surface until months or even years have passed. The symptoms often continue for years after the trauma, or they may subside and return later in life, if an event triggers memories of the trauma (1). Usually, symptoms are easy to identify, resembling to stress, anxiety and depression.

Signs and symptoms, which are characteristic for PTSD, if they have lasted for a month or more after the event, include: re-experiencing the event, with recurrent and unwanted memories of the event, nightmares of it, flashbacks (acting/feeling as though the event is happening again), distress and fear when reminded of the event and psychological reactivity – feeling jumpy, startled or anxious, when reminded of the event; persistent avoidance of any reminders of the event, the subject is avoiding thinking or talking about the trauma, is avoiding activities, places or people reminding of the event, it has no memory of an important aspect of the event, is detached or estranged from others, has a limited range of emotions and the feeling that he will not live long; persistent feelings of anxiety and/or physical reactivity – difficulty of falling or staying asleep, is cranky, irritable or angry, has attention and concentration problems and an exaggerated startle response (2, 9).

Besides an increased risk of developing PTSD during adulthood, PTSD in children may show characteristic features (10).

TREATMENT

Besides psychotherapy, cognitive be-

havioral therapy and eye movement desensitization and reprocessing (EDMR), several classes of psychotropic drugs are used in the treatment of PTSD.

Studies on the US troops in Iraq, showed that the use of morphine in the early stages of treatment, resulted in a significantly lower rate of PTSD, compared to those who did not receive morphine (11).

Selective serotonin reuptake inhibitors (SSRIs) are considered a first-line drug treatment; fluoxetine, paroxetine, citalopran, fluvoxamine and sertraline have data to support their use (12).

Antipsychotics as Risperidone are used in dissociation, mood issues and aggression.

Beta blockers (Propranolol) are effective in reducing hyperarousal symptoms, including sleep problems.

Alpha-adrenergic agonists, Clonidine can be helpful in startle, hyperarousal and general autonomic hyperexcitability (13).

Monoamine-oxidase inhibitors, as Phenelzine (Nardil) are effective against hyperarousal and depression and are especially effective with nightmares.

Trycyclic anti-depressants (amitrptyline and imipramine) are used for the treatment of avoidance and intrusive symptoms.

Anti-convulsants, mood stabilizers, such as Carbamazepine is reducing arousal symptoms related to noxious affect and aggression. Topiramate (Topamax) is strongly effective in flashbacks and nightmares, with no reduction of effect over time (14).

Atypical antidepressants as Nefazodone (Serzone) are effective against secondary depression, anxiety, sexual dysfunction symptoms and sleep disturbances (15).

MDMA (3, 4-Methylenedioxymetamphetamine), commonly known as ecstasy is a drug of the phenetylamine and amphetamine families. Studies in the U.S., Switzerland and Israel are evaluating the efficacy of MDMA – assisted psychotherapy for treating PTSD (17).

Cannabis was also used in the treatment of PTSD; there are studies which demonstrate that cannabis provides control and amelioration of chronic stressors, without adverse side effects (16).

NOUTĂȚI

FOXO1 JOACĂ UN ROL CHEIE ÎN REGLAREA METABOLISMULUI ENERGETIC

Factorul de transcripție FOXO1 joacă un rol deosebit în reglarea metabolismului prin modularea activității insulinei şi leptinei în numeroase celule, inclusiv la nivel neuronal. Nucleul ventromedial hipotalamic (VMH) reprezintă un situs cheie la nivelul căruia acționează FOXO1. Expresia FOXO1 în neuronii VMH mediază homeostazia glucidică şi balanța energetică. A fost demonstrată creşterea consumului energetic la modele animale la care lipseşte FOXO1 în neuronii SF-1 (steroidogenic factor 1) din VMH. De asemenea, şoarecii au prezentat toleranță crescută la glucoză prin creşterea sensibilității la insulină în mușchii scheletici. Receptorul nuclear SF-1 a fost identificat drept țintă directă a FOXO1 la nivelul VMH. Datele sugerează că rețelele transcripționale modulate de FOXO1 în neuronii VMH reprezintă componente cheie în reglarea homeostaziei glucidice şi a metabolismului energetic (Kim KW, Donato J Jr, Berglund ED et al. FOXO1 in the ventromedial hypothalamus regulates energy balance. *J Clin Invest*. 2012. pii: 62848. doi: 10.1172/JCI62848).

OPTIMIZATION OF CULTURE CONDITIONS FOR BONE MARROW STROMAL CELLS IN RPMI-1640 MEDIUM (Abstract): Bone marrow mesenchymal stem cells are important for both research and clinical purpose. A number of culture methods for these cells are available on the market, many of them consisting of specialized growing media in combination with growth factors. Our goal was to optimize a less expensive culture method for bone marrow mesenchymal cells. **Material and methods**: Eight samples of bone marrow aspirates from patients were used. Out these 8 samples 2 were from healthy people, 3 from chronic granulocytic leukemia patients, 2 from multiple myeloma patients and 2 from patients with myelodysplastic syndrome. Bone aspirates from healthy people were used to optimize the culture method and the rest were used for testing the optimized method. Two methods were tried: 1. Cell culture starting from whole bone marrow, 2) cell culture after bone marrow separation in density gradient with Histopaque. **Results**: Cell culture starting from whole bone marrow gives better yields for mesenchymal stem cells than methods which include gradient density separation of mononuclear cells with Ficoll-Histopaque. **Conclusions:** We have optimised a less expensive cell culture method for bone marrow mesenchymal cells. **Key words**: BONE MARROW STROMAL CELLS, CELL CULTURE, OPTIMIZATION METHOD.

Stem cells zygotic, embryonic or adult have the ability of self-renewal and differentiation into at least one mature specialized cell (1). The ability of adult stem cells to differentiate into other cells is in relation with their origin (1). Bone marrow contains a heterogeneous population of cells which includes adipocytes, reticular cells, macrophages, vascular endothelial cells, smooth muscular cells and stroma cells (2). Within bone marrow we find adult stem cells with restrictive genetic programs like hematopoietic stem cells which differentiate into leukocytes, erythrocytes, or megakaryocytes and mesenchymal stem cells (MSCs) or of bone marrow stromal cells (BMSCs) that can differentiate to form bone, cartilage, or adipose tissue (3, 4). The presence of stem cells is not limited to bone marrow, these cells have been observed in liver, periosteum, blood and support tissues in muscles (5).

Unlike embryonic stem cells, adult stem cells have a limited potential of differentiation, a trait that could be useful in many therapeutic applications (6, 7). Adult stem cells are an attractive source for cell therapy, gene therapy and tissue engineering. As clinical application, MSCs demonstrates great therapeutic characteristics in wounds and ischemic situation (8) and promise new solutions for bone repair (9-13) cartilage repair (14, 15) and neural repair (16, 17). Since MSCs play a significant role in tissue repair and homeostasis, new strategies in aesthetic surgery could be elaborated with these cells for tissue augmentation and regeneration (18).

With so many clinical applications for BMSCs, it is obvious how important they become for medicine. There are many specialized culture medium for BMSCs, but in general they are very expensive. We present here a cost effective optimized method for BMSCs culture using a less expensive culture medium.

MATERIAL AND METHODS

We have selected 8 samples of bone marrow aspirates from patients of Haematology Clinic in „St Spiridon" Clinical University Hospital Iasi. Samples have been received for FACS diagnostic tests and a small quantity has been used for our research experiment which was conducted according to institutionally approved protocols and legal form of informed consent. Out these 8 samples 2 were from healthy people, 3 from chronic granulocytic leukemia patients, 2 from multiple myeloma patients and 2 from patients with myelodysplastic syndrome. Bone aspirates from healthy people were used to optimize the culture method and the rest were used for testing the optimized method. We have tried two methods: 1. Cell culture starting from whole bone marrow, 2) cell culture of BMSCs after bone marrow separation in density gradient with Histopaque®-1077 (Sigma Aldrich).

Whole bone marrow method:

Three mL of bone marrow aspirate from one source is mixed with 7 mL of total medium which is composed by RPMI-1640 (Sigma Aldrich) supplemented with 10% FBS Gibco® (fetal bovine serum), 2% fresh L-glutamine 200 mM (Sigma Aldrich) and 1% penicillin-streptomycin Gibco®. PH of RPMI-1640 medium was adjusted to 7.35 prior using. This mixture with a total volume of 10 mL was plated in one 25 cm^2 cell culture flask (Greiner Bio-One) with filter cap. This was done for both samples from healthy people. Flasks were incubated at 37°C in a 5% CO2 humidified atmosphere. Medium was changed after 4 days first and every 3 days next.

Density gradient separation method:

This method is based on the fact that Ficoll solution or Histopaque solution, mononuclear cells and other marrow components have different densities. If centrifuged, it can be observed that mononuclear cells including BMSCs have a lower density than Histopaque so they form a ring on top of Histopaque, erythrocytes and granulocytes have a higher density than Histopaque so they settle under it.

In a 15 ml conic tube (Falcon), on top of one volume Histopaque, 1.5 volume of bone marrow from one source is added very slowly. Tube is centrifuged at 600 x g for 30 minutes at room temperature with brake and acceleration set to the lowest. After centrifugation, the mononuclear ring containing BMSCs is collected with the help of a sterile pipette. Total culture medium identical to the one described in pre-

vious method is added to BMSCs solution to a total volume of 10 ml. This final BMSCs solution is plated in a 25 cm^2 cell culture flask as in the first method with the same incubation conditions.

RESULTS AND DISCUSSION

During the optimization step for method one (whole bone marrow) after first 4 days from plating it was observed that culture medium was rich in diverse components of bone marrow: precursors for red and white lines of blood, adipocytes, and small dispersed colonies of BMSCs (fig.1a,1b).

Thanks to their adherence property, BMSCs adhere to the flask and separate themselves from the other cell types creating a halo around; they are much bigger, elongated, fibroblast like cells, and have a translucent look (fig. 1a, 1b). BMSCs from whole bone marrow method have reached 100% confluency after 3 weeks (fig.1c) while BMSCs separated with Histopaque (the second method) have reached 90% confluency after 4 weeks (Fig. 1e). This happened for both samples from healthy volunteers.

Since the whole bone marrow method gave better results, the other samples from patients with various pathologies were used next to test this method.

BMSCs from multiple myeloma patients have formed colonies with halo around within the first 4 days in a similar manner (Fig. 2a). Colonies were able to reach confluency within 3 weeks (fig. 2c).

BMSCs from patients with chronic granulocytic leukemia did not pose particular problems; they have reached 80% confluency after 3 weeks (fig. 3c).

For patients with myelodysplastic syndrome, cell culture was slower (fig. 4). Colonies couldn't reach more than 60% confluency after 3 weeks.

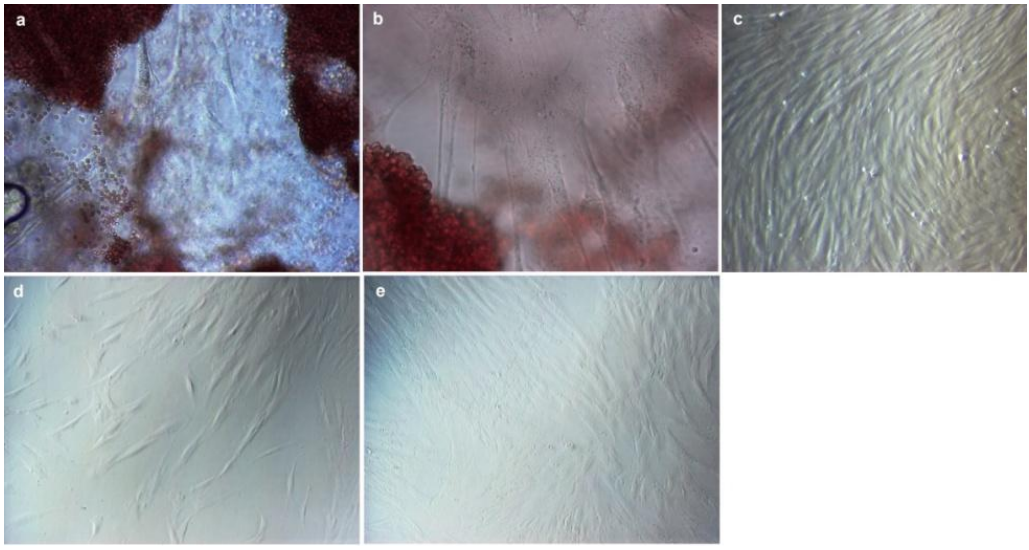

Fig. 1. Healthy volunteer BMSCs (bone marrow stromal cells) culture, phase contrast microscopy, objective 20X: a), c), d), e). Objective 40X: b) method one (from whole bone marrow) : a), b), c). Method 2 (Histopaque): d), e). Time in culture: a) and b): 4 days. c): 21 days. d): 21 days e): 28 days.

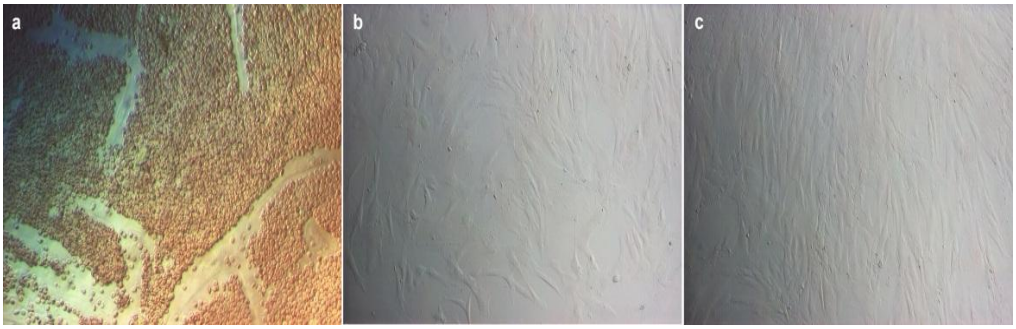

Fig. 2. Multiple myeloma BMSCs (bone marrow stromal cells) cultures, phase contrast microscopy, objective 20X. Time in culture: a) 4 days, b) 14 days, c) 21 days.

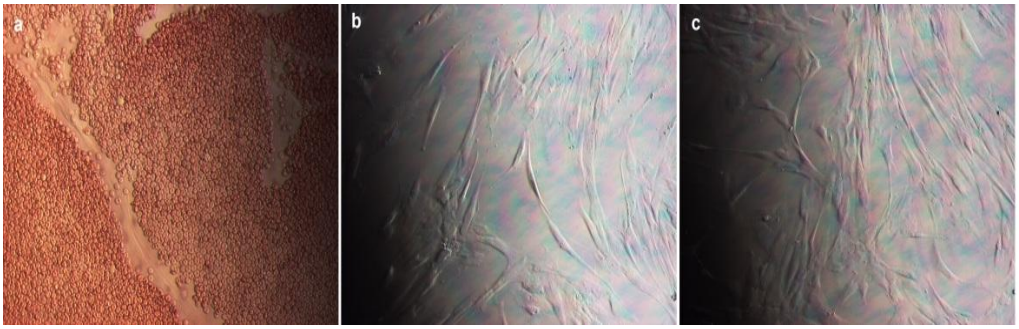

Fig. 3. Chronic granulocytic leukemia BMSCs (bone marrow stromal cells) culture, phase contrast microscopy, objective 20x.
Time in culture: a) 4 days, b) 14 days, c) 21 days.

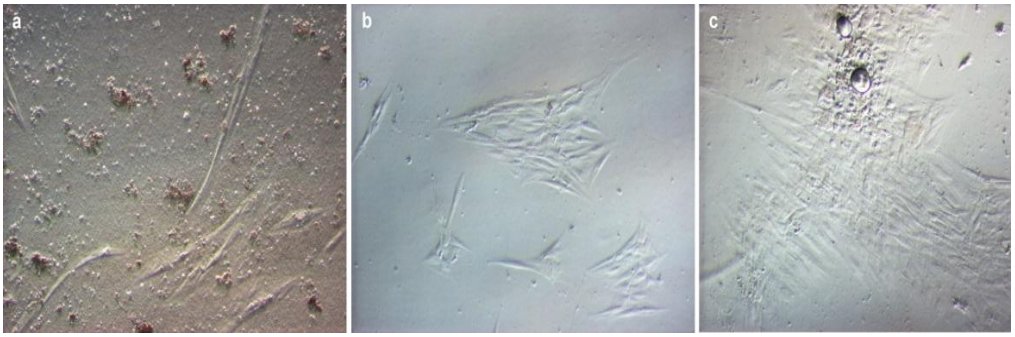

Fig. 4. Myelodysplastic syndrome BMSCs (bone marrow stromal cells) culture, phase contrast microscopy, objective 20x. Time in culture: a) 4 days, b) 14 days, c) 21 days.

BMSCs from culture were tested for specific stromal markers: endogline (CD105), Thy1 (CD90), integrin β1 (CD29), ICAM1 (CD54). All have proven to be positive, ensuring thus that our cell culture experiment was successful.

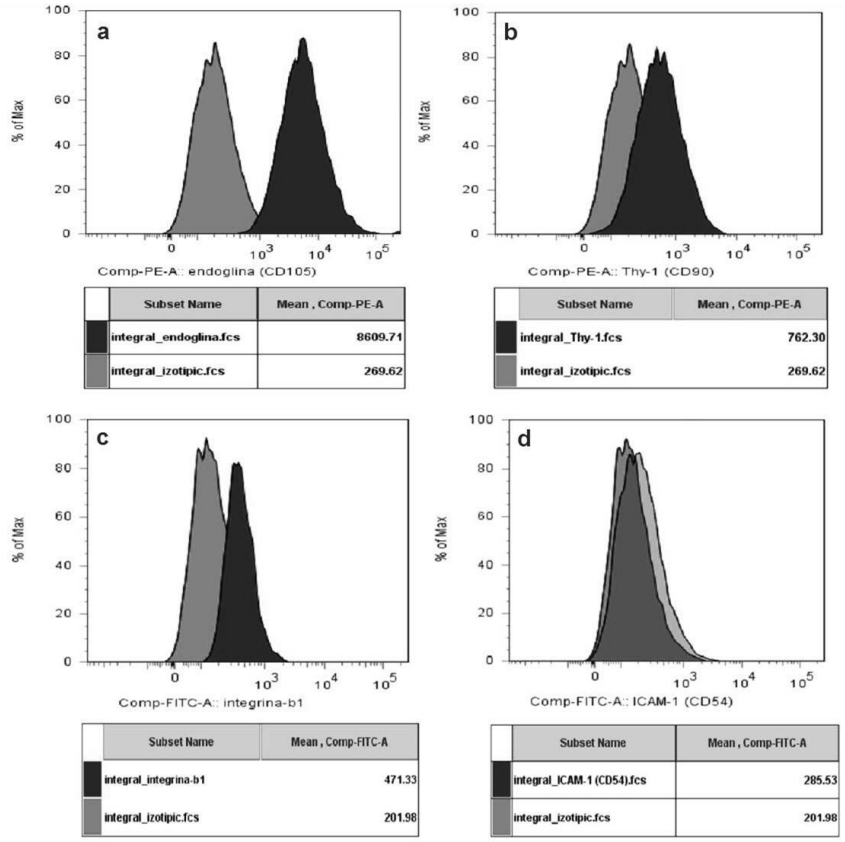

Fig. 5. Image shows phenotypic expression pattern for: a) endogline (CD105), b) Thy1 (CD90), c) integrin β1 (CD29), d) ICAM1 (CD54). Histograms overlay display mean fluorescence value obtained by surface staining BMSCs with mouse antibodies specific for human CD105, CD90, CD29 and CD54. Antibodies where conjugated with phycoerythin (Santa Cruz). In light grey: isotopic control. (Data acquisition was performed with FACSCantoII machine utilizing FACSDiva software, BD Biosciences and data analysis with FlowJo software, Tree Star, Inc.)

CONCLUSIONS

We have presented here an optimized method for BMSCs culture using RPMI-1640 medium without growth factors. This method is reliable and less expensive compared to other methods which require specialized stem cell media.

Our experiments have shown that method involving platting a mixture of whole bone marrow with growth medium gives better BMSCs yields than method which starts from Histopaque separated mononuclear cells. We believe there are two reasons for this: bone marrow present in culture mimics the physiological medium in organism and has numerous support ingredients; the second reason would be that a number of BMSCs are lost during Histopaque separation, this is important because BMSCs concentration in bone marrow is low.

This optimized method has proven to be successful for bone marrow samples com-

ing from healthy donors as well as for samples coming from patients with different pathologies.

THE ROLE OF DNA REPAIR BY HOMOLOGOUS RECOMBINATION IN ONCOGENESIS

Gabriela Bordeianu[1], F. Zugun-Eloae[2], M. G. Rusu[1]

2. Department of Immunology

THE ROLE OF DNA REPAIR BY HOMOLOGOUS RECOMBINATION IN ONCOGENESIS (Abstract): DNA repair by homologous recombination (HR) may be regarded as the two faces of a coin: lowering the oncogenetic potential (precise repair with no consequences on genomic status) or increasing it (deleterious action which may determine chromosome rearrangements such as loss of heterozigosity). Inherited mutations in genes involved in HR are associated with gene rearrangement and may be a prerequisite for tumor development in some cancer-prone hereditary diseases like Bloom, Werner and Rothmund-Thomson syndromes. Normal eukaryotic cells show some degree of balance between various mechanisms of repair. This review presents the main mechanisms and pathways of homologous recombination repair *(*synthesis-dependent single strand annealing, constitution of Holliday junctions with their resolution mechanisms and repair by break induced replication), the proteins involved in it and their contribution to oncogenesis. **Key words:** LOH, SDSA, BIR, HOLLIDAY JUNCTION, CROSSING OVER

Genome mutations in somatic cells are the main cause of any form of cancer. Mutated genes have to code for proteins that are involved in proliferation, differentiation, apoptosis or adhesiveness. There are two types of genes involved in oncogenesis: oncogenes and tumor suppressor genes. Oncogenes are gain-of-function mutated alleles of the proto-oncogenes (promoting cells proliferation or invasiveness). They have a dominant action at molecular level, because they present a gain of function. Thus, oncogenes can promote proliferation even in heterozygous conditions. Tumor suppressor genes encode proteins which are inhibitors of cell proliferation. Their loss-of-function by a recessive mutation promotes cell proliferation only in homozygotes. In heterozygous they do not promote proliferation because they are recessive. Genomic reshaping caused by homologous recombination (HR) can lead to loss of heterozogosity (LOH) (1). LOH is not the only oncogenetic mechanism; defects in others repair processes such as mismatch repair (MMR), base excision repair (BER), nucleotide excision repair (NER), non-homologous end joining (NHEJ) can lead to oncogenesis. This review only refers to HR as an oncogenetic mechanism; excellent recent reviews on the other mechanisms are available (2). Broken chromatids which are repaired by HR arise during the physiological processes such as: normal

replication, cutting of DNA strands by topoisomerases to facilitate the access of transcription factors etc. Also, broken chromatids are due to environmental influences such as: chemicals-pesticides, industrial pollutants, tobacco smoke, electromagnetic radiation -UV light, X-rays, radioactivity. Although these errors may be considered detrimental to the organisms housing them, they may also be regarded as the evolution engine (3).

HR is a multistep mechanism of repair that restores both continuity and correctness of broken chromatids using the redundant information of a sister or homologous chromatid with the aid of many proteins which are conserved in different organisms. These proteins are usually homologous in amino-acid sequence and similar in function (orthologs see tab. I). A description of double strand breaks repair by HR is presented in the following paragraph and in figure 1.

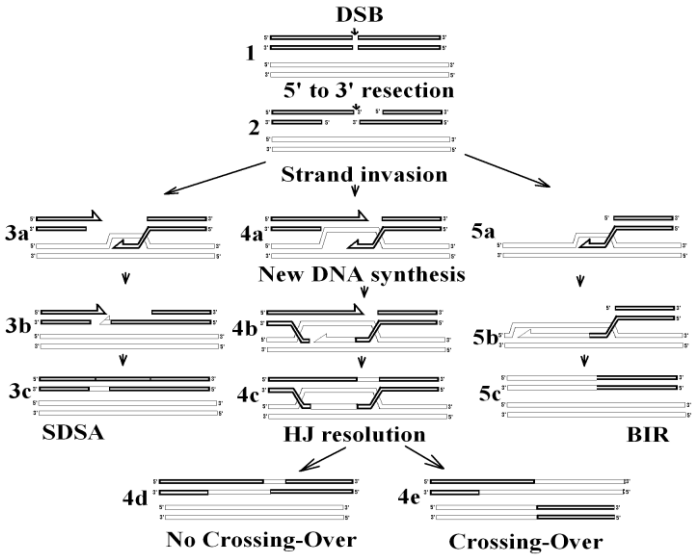

Fig.1. The mechanism of homologous recombination (HR) - data from ref. (12,13).

First, the broken duplex aligns to one of a sister chromatid or a chromatid of the homologous chromosome. The event is facilitated by protein Rad50 (1 in the fig.1). The two ends of the double-strand break are trimmed by shortening one strand from its 5' end so that a longer strand with a 3' end results (overhang). The operation is dependent on the nucleasic activity of Mre11, associated in a complex with Rad50 and Nbs1 (MRN complex). This event is named *end processing* (4). Sae2/CtIP functions with MRX/MRN complex either to activate the Mre 11 nuclease or via the intrinsic endonuclease, in the initial step to trim the duble-strand ends (2 in fig.1) (5). The single-stranded overhang is coated by Replicating Protein A (RPA). The single-stranded overhang invades the homologous duplex and anneals with its complementary strand. This process named *strand exchange* is mainly catalyzed by Rad51, a protein functionally similar with RecA in E.coli (3a, 4a, 5a of the fig.1, see also the tab. I) (6). Rad51 is a

homopolymer that wraps single-stranded invading strand after it is detached from the RPA. The process is mediated by the Rad51 paralogs (the Rad55/Rad59 complex in yeast, Rad51B, Rad51C, Rad51D, Xrcc2 and Xrcc3 in mammalians) and by Rad52. In humans the Rad52 function may be overtaken by BRCA2 (7) (tab. I).

TABLE I

Types of proteins implied in HR and their function

Name of orthologs			**Essential of the protein's role in DSB repair**	**References**
Mammals	***S. cerevisiae***	***S. pombe***		
Mre11	Mre11	Rad32	Form a complex that shortens one strand at its 5' end.	(13, 14)
Rad50	Rad50	Rad50		
Nbs1	Xrs2	Nbs1		
RPA	RPA	RPA	Heterotrimeric single-strand binding protein.	(15, 16)
Rad51	Rad51	Rhp51	Recombinase functionally similar to RecA from *E. coli*.	(13, 16)
Rad52	Rad52	Rad22	Mediates forming of the DNA-Rad51 filament, the strand exchange and the second-end capture.	(7, 13, 17)
Brca2	?	?	A protein mediating checkpoint responses and DNA repair.	(18, 19)
?	Rad55	Rad55	The orthologs in mammalians are unknown.	(7)
?	Rad57	Rhp57		
Rad54	Rad54	Rad54	Facilitates the strand exchange and the branch migration.	(20, 21)
BLM	Sgs1	Rqh1	RecQ type helicases. Resolve D-loops and Holliday junctions;	(22)
WRN				
Fbh1	Srs2	Fbh1	F-box helicase; disrupts the DNA-Rad51 filaments.	(10)
Mus81	Mus81	Mus81	Resolve Holliday junctions	(11, 12)
Eme1	Mms4	Eme1		

Also important for this process is a helicase function, which may be provided by Rad54, which locally denatures the intact duplex. The result of the strand exchange is called a *D loop* (fig. 1, 3a, 4a, 5a). The events described so far are common to any HR. Further, there are three alternative pathways along which HR can continue:

- *Synthesis-dependent Single Strand Annealing (SDSA)*; a replicative DNA pol-

ymerase adds nucleotides on the 3' end of the invading strand, according to the template complementary strand of the intact duplex. A possible evolution of the D-loop may be that its lengthened invading strand is unwinded from its complementary strand of the intact duplex (this may be catalysed by helicases such as RecQ class helicases (Sgs in yeast, Wrn or Blm in insects and humans) (8-9) or F-box helicases (10). The former invading strand may recapture the second end, and reanneal with its original complementary strand (3a, 3b, 3c).

- *Break Induced Replication (BIR*); at the level of D-loop a new replication fork is formed and the replication continues to the end of the chromatid causing the loss of all genetic information of the broken chromatid from the break down to its end. This can lead to the loss of heterozygosity when the model chromatid belong to the homologous chromosome (5a, 5b, 5c).

- *Holliday junctions (HJ) formation, migration and resolution*; the D loop may migrate (process called *branch migration*) due to the helicase function of Rad54 making the strand complementary to the invading strand available as a template for the synthesis by addition of nucleotides to the 3'end of the invading strand. Then, with a minimal unwinding, the 3' end of the invading strand can recapture its second end. This results in a *Hollyday junction (HJ)*. The symmetrical reciprocal invasion of the 3' ended overhang of the other end can lead to a double Hollyday junction (4b). HJs are resolved by endonucleolytic breakage and ligase rejoining and have one of two alternative endpoints (depending on which strands are endonucleolytically broken): crossover chromatids or non-crossover chromatids (4d, 4e). Four pathways are considered to be implied in this process: resolution by MUS81-EME1 (11,12); dissolution by the helicase-topoisomerase complex BLM/TOPIII/RIM1 (7, 11) resolution by GEN1 (11,13) and the endonuclease SLX1-SLX4 (11).

Repair by SDSA forms non-crossover products with minimal consequences compared with Holliday junctions which can be dissolved in a non-crossover or resolved in cross-over products (reciprocal exchange of genetic information and possible LOH). Moreover, the repair by break-induced replication (BIR) can also lead to the loss of heterosigosity (LOH). For a correct strand displacement of invading strand helicases are necessary. The enzymes are required for prevention and/or resolution of aberrant DNA structures that usually lead to the loss of heterozigosity. RecQ family helicase are encoded by BLM genes and, in human there are four paralogues: WRN, RECQ1, RECQ4 and RECQ5. Germinal mutation in these genes can lead to genetic diseases with cancer predisposition such as Bloom's syndrome (BLM), Werners's syndrome (WRN), Rothmund–Thomson syndrome, Baller–Gerold syndrome and RAPADILINO syndrome (RECQ4) (19).

Summarizing, homologous recombination can be involved in oncogenesis in two ways: 1) its insufficiency may lead to oncogenetic mutations or to alternative repair mechanisms promoting gross genomic rearrangements that also lead to oncogenesis and 2) its presence may lead to the loss of heterozygosity, an important oncogenetic process. In principle, homozygosity is the result in any kind of the homologous repair because of replacing the lost information in one chromosome with the information of the homologous chromosome. However, among the different of its alternative pathways: SDSA, crossing over and

BIR (see previous paragraphs) some have a greater oncogenetic potential than others. SDSA leads to LOH only in the neighborhood of the lesion repaired and a heterozygous mutation in a tumor suppressor gene becomes homozygous only when the lesion is located in it or near it. The probability of such a lesion is very small and so SDSA has a negligible oncogenetic potential. Crossing over and BIR, on the other hand, result in very long sequence replacements (from the lesion to the telomere) and the probability of turning a heterozygous tumor suppressor mutant allele into a homozygous is considerably greater and their oncogenetic potential is correspondingly greater. Therefore it is not surprising that genetic diseases such as Bloom, Werner and Rothmund-Thomson syndromes with loss-of-function mutations in helicases predispose to cancer. The absence of helicases function reduces the possibility of repair by SDSA and channels the repair to BIR or HJ resolved by crossing over. It is also of interest to evaluate the oncogenetic potential of HR with respect to other repair mechanisms. The fact that genetic diseases with mutations in genes encoding proteins involved in the first stages of HR (Mre11 mutated in the Ataxia telangiectasia-like syndrome and Nbs1 mutated in the Nijmengen breakage syndrome) predispose to cancer suggests that it is smaller than other repair mechanisms such as non-homologous end joining (NHEJ). This suggestion has been recently confirmed: BRCA1 (with its loss-of-function mutations predisposing to breast and ovarian cancer) inhibits the function of p53BP, a protein that blocks the MRN complex. When p53BP escapes from the control of BRCA, MRN does not function, homologous recombination cannot be started and repair by recombination is channeled to NHEJ (23).

CONCLUSIONS

Although of a smaller oncogenetic potential than other DNA repair mechanisms, homologous recombination with LOH remains an important cause that has to be taken into account in explaining and mastering of cancer.

FUNCTIONAL REEDUCATION OF FLEXOR TENDONS WITH ASSOCIATED LESSIONS IN ZONE II – COMPARATIVE STUDY (Abstract) : Regaining satisfactory digital function after flexor tendon laceration and repair has long been one of the most important problems in hand surgery. But optimal therapy is often difficult to ascertain, given the plethora of immediat postoperative protocols published in the scientific literature. **Aim**: The purpose of this study is to compare the functional results between Kleinert, Silfverkiöld, Gratton and Strickland protocol towards evaluate them by interconnection and with the literature. **Material and methods**: The prospective study enorolled 75 patients who presented in our cabinet consecutives during 1.05.2008-1.12.2010. The subjects were evaluated regarding Total active motion test and Grip strenght test at 12 weeks postoperative. **Results**: We found the best results to Gratton group, followed by Strickland, Silfverkiöld-May and Kleinert groups. **Conclusions**: We conclude that, for the tendinous lessions with associated injury (nervs and vessels) in zone II, our first therapeutical indication is to use the Gratton protocol. **Key words**: FUNCTIONAL REHABILITATION, FLEXOR TENDONS, ZONE II

Reeducarea precoce postoperatorie a tendoanelor flexoare reprezintă un factor important pentru buna funcţionalitate a mâinii, reducând formarea de aderenţe în canalul sinovial, stimulând refacerea suprafeţelor de glisare şi facilitând formarea unui calus tendinos mai rezistent. Dar protocolul terapeutic optim este greu de ales, datorită numărului mare de lucrări din literatura de specialitate. Prin acest studiu, analizând rezultatele privind mobilitatea articulară şi forţa musculară, am încercat să găsim o posibilă ierarhizare a unor protocoale des folosite, servind ca ghid pentru terapeuţii specializaţi în terapia mâinii, care îşi vor putea alege protocolul adecvat.

MATERIAL ŞI METODE

Au fost luaţi în studiu 75 pacienţi care au prezentat leziuni ale tendoanelor flexoare cu leziuni asociate, care au fost trataţi chirurgical în Secţia de Chirurgie Plastică şi Reconstructivă a Spitalului Clinic de Urgenţe ’’Sf. Ioan’’ din Iaşi şi secţiile din

teritoriul Moldovei, care s-au adresat pentru tratament de reeducare funcţională la Cabinetul Medical Individual ,,Ţopa Ionuţ" în intervalul mai 2008 – decembrie 2010, unde le-au fost aplicate ortezele şi programele de reeducare funcţională. Evaluările au fost efectuate atât în spital cât şi la cabinet. Au fost selecţionate cazurile pacienţilor ce s-au prezentat consecutiv, care au putut fi urmăriţi până la 12 săptămâni postoperator (4 săptămâni la domiciliu sub protecţia ortezei şi 4 săptămâni la cabinet sub supravegherea personală) şi care s-au prezentat pentru evaluarea funcţională de la 12 săptămâni postoperator. Dintre aceştia 57 au fost bărbaţi (76%) şi 18 femei (34%) cu vârste cuprinse între 21 şi 69 de ani, 33 (44%) de pacienţi provenind din mediul urban şi 42 (56%) din mediul rural. Lotul de pacienţi a fost împărţit după momentul prezentării în tratament (pe perioade de 8 luni) în 4 grupuri la care s-au aplicat 4 protocoale terapeutice diferite:

– mai 2008-decembrie 2008 - 17 pacienţi – protocol Kleinert modificat (grupul Kleinert);
– -ianuarie 2009-august 2009 - 20 pacienţi - protocolul - Silfverkiöld şi May (grupul Silfverkiöld şi May);
– septembrie 2009-aprilie 2010 - 18 pacienţi - protocolul Strickland (grupul Strickland);
– mai 2010-decembrie 2010 - 20 pacienţi - protocolul Gratton (grupul Gratton).

Programul de reeducare funcţională

- *Protocol Kleinert modificat* (1,2,3). Orteze tip Kleinert modificate cu pumnul în 30° de flexie, articulaţiile metacarpofalangiene (AMF) în flexie 70°, articulaţiile interfalangiene (AIF) în poziţie neutră. Sub pliul palmar distal de flexie a fost aplicat pe orteză un scripete pentru direcţionarea elasticelor ataşate pe degetele operate pe direcţia scafoidului (fig. 1,2). În fiecare oră pacientul efectuează 10 repetări de extensie activă contra rezistenţei elastice şi flexie pasivă a degetului operat.

Fig. 1. Flexie pasivă AIF

Fig. 2. Flexie activă AIF

- *Protocolul - Silfverkiöld* (fig. 3,4). Orteză cu pumnul în neutru, flexie AMF 50-70° şi cu rezistenţe elastice ataşate pe toate cele 4 degete (four finger program)(4,5). În fiecare oră 10 repetări extensie activă, flexie dinamică şi flexie cu ,,place-hold" 2-3 secunde (se duc cu mâna sănătoasă degetele în diferite poziţii de flexie şi se menţin 2-3 secunde).

- *Protocol Strickland* (fig. 5,6). Orteză articulată (6,7) pentru exerciţii şi una dorsală de protecţie cu pumnul în flexie 20° şi AMF în flexie 50°. Orteza articulată permite flexia maximă a pumnului dar limitează extensia la 30°. În fiecare oră va efectua 15 repetări de flexie pasivă a AIFD; AIFP;

AMF în orteza statică urmate de 25 de repetări de plasare-menţinere a flexiei degetului pentru 5 secunde în orteza de tenodeză.

Fig. 3. Flexie pasivă AIF

Fig. 4. Flexie activă AIF

Fig. 5. Flexie pumn-extensie degete

Fig. 6. Extensie pumn 30°-flexie cu menţinere 5 s

- *Protocolul Gratton*. Orteză dorsală ce menţine pumnul în flexie 20°, AMF în flexie 80-90° iar AIF în extensie (fig. 7,8). Orteza este mai lungă cu 2 cm pentru a împiedica folosirea mâinii. În fiecare 4 ore cu toate degetele 2 repetări de flexie pasivă, flexie activă, extensie activă. Scopul primei săptămâni este obţinerea flexiei pasive complete, extensiei active complete, flexiei active de 30° pentru AIFP şi 5-10° pentru AIFD, cu o creştere graduală a flexiei active în următoarele săptămâni ajungând la 80-90° flexie AIFP şi 50-60° AIFD la sfârşitul celei de-a patra săptămâni (8).

Fig. 7. Orteză Gratton cu protecţie 20° AIFP

Fig. 8. Flexie activă 2 săptămâni

Evaluarea pacienţilor s-a făcut după următoarele teste :

- *Testul TAM al lui Strickland – versiunea a-2-a* (9). Este considerat testul cel mai bine adaptat leziunilor tendoanelor flexoare în zona a-II-a (1985). Constă în suma flexiei active a articulaţiilor interfalangiene minus deficitul de extensie şi se compară în procentaje cu valoare standard de 175°(tab. I).

TABELUL I

Strickland a-2-a versiune

Rezultate	Valoare comparativă	Procentaj
Excelent	>132°	75 – 100%
Bun	88 - 131°	50 – 74%
Mediu	44° - 87°	25 – 49%
Slab	<44°	< 25%

-Testul pentru măsurarea forţei prizei digito-palmare cu ajutorul dinamometrului Jamar. Această evaluare trebuie făcută bilateral şi care acordă mâinii dominante un procent de 100-120% faţă de cea nedominantă (10). Poziţia pacientului trebuie cu umărul în abducţie 30°, cotul flectat la 90°, antebraţul în poziţie neutră, pumnul în extensie 30° şi înclinare cubitală de 15° (tab. II).

TABELUL II

Testul JAMAR

Rezultat	Mâna dominantă	Mâna nedominantă
Bun	≥80% faţă de cea neafectată	≥60% faţă de cea neafectată
Slab	<80% faţă de cea neafectată	<60% faţă de cea neafectată

REZULTATE

Distribuţia cazurilor în funcţie de sexul pacientului, mediul de provenienţă şi vârstă nu prezintă diferenţe semnificative între grupurile luate în studiu (tab. III), ceea ce demonstrează omogenitatea grupurilor investigate după protocolul aplicat.

TABELUL III

Semnificaţia statistică a diferenţelor pe sex, mediu de provenienţă şi vârstă

Subgrupuri comparate		Sex		Mediu de provenienţă		Vârstă	
		χ^2	p	χ^2	p	t-Student	p
Kleinert	Silfverkiöld	0,06	0,811	0,32	0,571	1,18	>0,05
	Strickland	0,45	0,500	0,04	0,836	1,68	>0,05
	Gratton	0,16	0,686	0,07	0,792	1,46	>0,05
Silfverkiöld	Strickland	0,32	0,573	0,12	0,732	0,37	>0,05
	Gratton	0,14	0,705	0,10	0,752	0,26	>0,05
Strickland	Gratton	0,04	0,836	0,09	0,770	0,12	>0,05

Rezultatele excelente şi bune ale scorului TAM au variat ca frecvenţă de la 80%, care clasează protocolul Gratton pe locul 1, până la 70,6% clasând protocolul Kleinert modificat pe locul 4 (tab. IV).

Rezultatele bune ale scorului JAMAR au variat ca frecvenţă de la 85%, care clasează tot protocolul Gratton pe locul 1, până la 76,5% clasând protocolul Kleinert modificat pe locul 4 (tab. V).

TABELUL IV

Rezultatele Total active motion

Clasament	Protocol	E + B	M + S
1	Gratton	80,0%	20,0%
2	Strickland	77,8%	22,2%
3	Silfverkiöld	75,0%	25,0%
4	Kleinert	70,6%	29,4%

TABELUL V

Rezultatele la JAMAR

Clasament	Protocol	Bun	Slab
1	Gratton	85,0%	15,0%
2	Strickland	83,3%	16,7%
3	Silfverkiöld	80,0%	20,0%
4	Kleinert	76,5%	23,5%

Pentru a studia eficienţa aplicării scorului JAMAR comparativ cu scorul TAM se analizează comparativ pe tipuri de protocoale sensibilitatea şi acurateţea metodei de evaluare (tab. VI).

Se evidenţiază cea mai bună acurateţe la pacienţii din grupul la care s-a aplicat protocolul Gratton, urmat de subgrupul Strickland, Silfverkiöld şi May şi pe ultimul loc Kleinert, ceea ce confirmă ierarhia anterior stabilită (tab. IV,V, VI, VII).

TABELUL VI

Analiza comparativă a acurateţei testelor TAM şi JAMAR

Lot A2	VPP (%)	VPN (%)	Sensibilitate (%)	Specificitate (%)	Acurateţe	p
Kleinert	91,7	40,0	78,6	66,7	72,7	0,022
Silfverkiöld	93,3	40,0	82,4	66,7	74,6	0,009
Strickland	92,9	50,0	86,7	66,7	76,7	0,043
Gratton	93,8	50,0	88,2	66,7	77,5	0,028

TABELUL VII

Ierarhizarea protocoalelor la 12 săptămâni postoperator

Ierarhie	TAM	JAMAR	TAM + JAMAR
1	Gratton	Gratton	Gratton
2	Strickland	Strickland	Strickland
3	SMay	SMay	SMay
4	Kleinert	Kleinert	Kleinert

DISCUŢII

Testarea după *Total Active Motion (TAM)* la 12 săptămâni postoperator a evidenţiat rezultate excelente şi bune cu o variaţie între 71 şi 80%, clasând protocoalele terapeutice astfel: Gratton (80%), Strickland (78%), Silfverkiöld şi May (75%) şi Kleinert modificat (71%). Valorile excelente/bune obţinute la testul TAM în acest studiu sunt comparabile cu cele din literatura de specialitate: 75% Chambon(11), 84% Peck (12), 71% Hung(13), 81% Silfverkiöld şi May (14), 75% Riaz (15), 72% Evcik (16), 81% Graf (17).

Testarea după *Grip strenght test (dinamometrul JAMAR)* a găsit o variaţie ca frecvenţă a rezultatelor bune de la 92% până la 75% şi a condus la următoarea clasificare a protocoalelor folosite : Gratton (85%), Strickland (83%), Silfverkiöld şi May (80%) şi Kleinert modificat (77%). Forţa de prehensiune reprezintă un factor important în funcţionalitatea mâinii dar

numărul de lucrări publicate la care ne putem raporta privind rezultatele obţinute la Jamar este mic : 71% Bal (18), 94% Riaz (15), 67% Evcik(16), 72% Chan (19), 81% Kitis (20).

Testarea acurateţii celor două teste ne-a indicat aceeaşi ordine de utilizare a protocoalelor terapeutice.

CONCLUZII

Coroborând rezultatele testelor aplicate pe loturile de pacienţi împreună cu interpretările statistice concluzionăm că, în cazul leziunilor tendoanelor flexoare cu leziuni asociate în zona II, indicaţia noastră de utilizare a protocoalelor este Gratton, Strickland, Silfverkiöld şi Kleinert.

NOUTĂȚI

LEZIUNEA ACUTĂ RENALĂ POATE FI MOTIV DE ÎNGRIJORARE PENTRU PROGRESIA CĂTRE BOALĂ RENALĂ CRONICĂ?

În timp, cât mai multe dovezi indică faptul ce atât incidenţa leziunii renale acute (AKI) cât şi a bolii renale cronice (CKD) la copii este în creştere, iar etiologia s- schimbat dramatic, sunt relativ puţine cunoştinţe cu privire la potenţialul tranziţiei de la AKI la CKD. Barierele majore în evaluarea potenţialului trecerii de la AKI la CKD sunt legate de lipsa de standarde pediatrice pentru definiţia AKI, atenţia fiind centrată numai pe copiii cu AKI ce primesc terapie de supleere renală, şi se recurge la nivelul seric al creatininei ca biomarker principal pentru a depista şi diagnostica AKI şi CKD. Date recente au validat un sistem multidimensional de clasificare al AKI la copii şi a sugerat sechele renale cronice în populaţia pediatrică cu AKI sau ca risc pentru AKI. În plus, un număr de noi biomarkeri au fost riguros validaţi ca indicatori precoci a CKD inicpientă. Autorii îşi stabilesc drept scopuri de a revedea modificările recente survenite în epidemiologia AKI şi CKD pediatrice, să exploreze potenţialul AKi de a progresa către CKD şi propunerea de noi paradigme clinice şi de cercetare pentru a elucida mai bine progresia AKI către CKD. (Goldstein SL, Devarajan P, Acute kidney injury in childhood: should we be worried about progression to CKD? *Pediatr Nephrol*, 2011; 4(26): 509-522).

MACROSCOPIC AND MICROSCOPIC LESIONS IN BRONCHIAL ASTHMA (Abstract): Bronchial asthma is a chronic inflammatory disease characterized by reversible airways obstruction, inflammation, and increased bronchial hyperresponsivennes. The aim of this study was to evaluate the macroscopic and microscopic airways lesions, using bronhoscopy followed by biopsy in 38 cases of Outpatient Department from Clinic of Pulmonary Diseases Iaşi, investigated between January 2005 - June 2008. Patients distribution according to the degree of severity was performed, using the international recommendations for asthma management of the Global Initiative for Asthma (GINA): intermittent (n=7 patients), mild persistent (n= 10 patients), moderate persistent (n= 16 patients), and severe persistent (n= 5 patients). 23,68% of patients had a chronic disease of more than 15 years. The endoscopic changes of the peripheral airways were represented by edema, congestion, bronchial stenosis and mucus hypersecretion. Microscopic routine exam showed epithelial lesions (epithelial desquamation, goblet cell hyperplasia, squamous metaplasia), basement membrane thickening, edema, increased vascularisation, glandular and muscular hypertrophy and bronchial inflammatory infiltrate. Although bronhoscopy exam offers important information regarding changes of the airway mucosa in bronchial asthma, it concomitantly provide bioptic control, as microscopic examination still represents the „gold standard" assessment of bronchial wall remodeling process. **Key words:** BRONCHIAL ASTHMA, BRONHOSCOPIC EXAM, MICROSCOPIC LESIONS

Astmul bronşic este o boală inflamatorie cronică a căilor respiratorii caracterizată prin obstrucţie bronşică difuză şi variabilă reversibilă în mod spontan sau sub tratament.

Evaluarea adecvată a modificărilor căilor aeriene în astmul bronşic se poate realiza prin fibrobronhoscopie, metodă invazivă care permite atât vizualizarea directă a căilor aeriene mari, cât şi practicarea lavajului bronhoalveolar şi/sau a biopsiei bronşice. Această metodă este frecvent greu efectuată şi acceptată de către unii pacienţi astmatici cu insuficienţă respiratorie. Fibrobronhoscopia permite caracterizarea macroscopică a leziunilor, oferind astfel o primă orientare asupra substratului morfologic asociat astmului bronşic (1,2). Suplimentar, lavajul bronhoalveolar aduce informaţii asupra leziunilor prezente la nivelul căilor aeriene mici şi a spaţiilor

alveolare (3,4). Biopsia bronşică constituie însă investigaţia relevantă pentru analiza mucoasei căilor aeriene, modificările instalate în evoluţia astmului bronşic fiind astfel certificate şi cuantificate prin examen microscopic (2,5).

Cu toate avantajele sale de necontestat, examenul fibrobronhoscopic – însoţit sau nu de biopsie bronşică nu este o metodă de rutină în evaluarea pacienţiilor cu astm bronşic (2). În contextul patologiei astmatice, investigarea fibrobronhoscopică este practicată în principal în scop de cercetare, fapt susţinut şi de numărul relativ mic de publicaţii din literatura de specialitate care au ca subiect examenul bronhoscopic la pacienţii astmatici (aproximativ 200 în 20 ani) (6,7). Cu toate acestea, paşii hotărâtori în descifrarea aspectelor fiziopatologice au fost realizaţi odată cu posibilitatea studierii, prin diferite metode, a fragmentelor bronşice recoltate pe cale fibrobronhoscopică, la pacienţii cu astm în stadii evolutive (8). Punctul de plecare este reprezentat de încadrarea pacienţilor după examinarea clinică şi în raport cu rezultatele testelor de explorare funcţională pulmonară, în raport de cele 4 trepte de severitate conform clasificării GINA 2006: astm intermitent, astm uşor persistent, astm moderat persistent şi astm sever persistent (9).

În contextul datelor raportate în literatură, studiul de faţă îşi propune să evalueze tipul şi amploarea leziunilor macroscopice ale peretelui bronşic la pacienţii astmatici, în corelaţie cu leziunile microscopice.

MATERIAL ŞI METODĂ

Lotul de studiu a fost reprezentat de 38 de pacienţi astmatici, sub tratament steroidian inhalator şi în stadii evolutive progresive, dispensarizaţi prin Ambulatoriul de Specialitate al Spitalului Clinic de Pneumologie Iaşi, în perioada ianuarie 2005 – iunie 2008.

Studiul s-a efectuat după consimţământul informat, conform ,,Ghidului informativ" care a realizat familiarizarea cu procedura şi obţinerea unei cooperări optime din partea pacienţilor. Metodologia de lucru a urmărit protocolul standard de pregătire (premedicaţie cu bronhodilatatoare cu acţiune scurtă pe cale inhalatorie (Salbutamol 2,5 mg în nebulizare sau 2 pufuri Ventolin) (10), benzodiazepine anxiolitice şi antitusive. Examinarea a fost efectuată sub administrare continuă de oxigen prin canulă nazală tip „ochelari", cu un debit de 1-2 l/min, dupa anestezia locală progresivă a zonelor reflexogene (faringe, laringe, trahee).

Toţi cei 38 de pacienţi cu astm bronşic au fost monitorizaţi atât pe parcursul procedurii, cât şi ulterior acesteia prin pulsoximetrie şi evaluarea semnelor vitale, timp de minimum 2 ore post-examinare.

Pentru efectuarea fibrobronhoscopiei s-au folosit videoendoscopul Olympus BFType 160, care a permis şi înregistrarea video a examenului, cu posibilitatea efectuării unor fotografii digitale, sau fibroscopul clasic Olympus BF1T60, cu canal peste 2,8 mm.

Pentru examenul microscopic, fragmentele de mucoasă bronşică recoltate bioptic au fost prelucrate conform protocolului standard şi colorate prin metoda Hematoxilină-Eozină.

Prelucrarea statistică a datelor a fost efectuată cu programul specializat SPSS, varianta 17 (11).

REZULTATE

Caracterizarea clinică în raport de severitate

În raport cu clasificarea GINA 2006 de încadrare pe trepte de severitate pacienţii au prezentat următoarea distribuţie: 7 cazuri cu astm bronşic intermitent, 10 cazuri cu astm bronşic uşor persistent, 16 cazuri cu astm bronşic moderat persistent şi 5 cazuri

cu astm bronşic sever persistent. Media VEMS (din valoarea sa prezisa) în cadrul lotului a fost de 78,3 +/- 22,6 % (tab. I).

În ceea ce priveşte vechimea bolii astmatice s-a constat un procent mai mare de pacienți (23,68%) care au prezentat o vechime a afecțiunii cuprinsă între 15 şi 20 ani (fig. 1).

TABELUL I

Mediile VEMS (% din prezis) în raport de severitatea astmului

VEMS (% din ideal)	**78.3±22.6**	**25.3**	**62.0**	**76.2**	**93.9**	**122.0**		
Astm intermitent (n=7)	106.3±14	88.0	92.8	111.0	119.0	122.0	0.010819	ss
Astm uşor (n=10)	94.5±6.3	82.0	92.0	93.7	100.0	103.0	0.000125	ss
Astm moderat (n=16)	66.7±6.2	59.2	62.0	64.5	70.3	79.8	0.000162	ss
Astm sever (n=5)	43.6±10.8	25.3	45.0	45.2	48.8	53.7	0.000126	ss

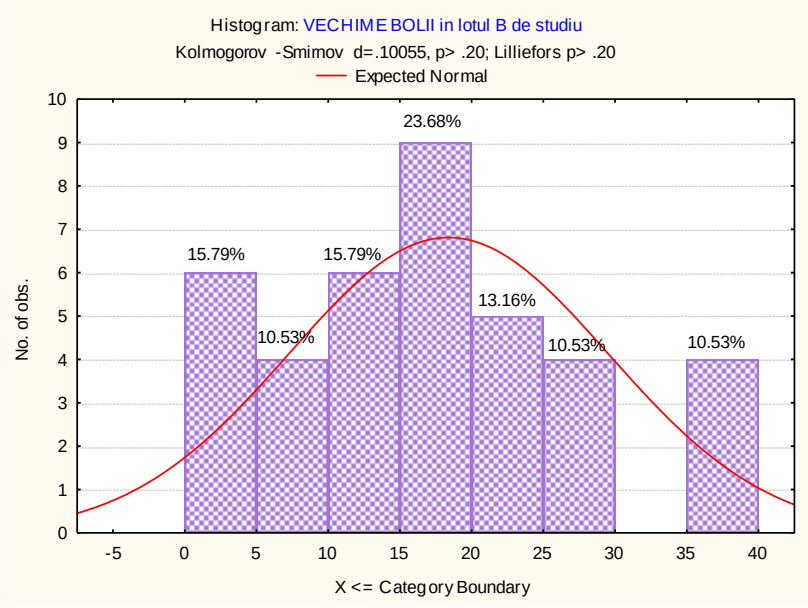

Fig. 1. Histograma valorilor vechimii afecțiunii în lotul de studiu

Profilul macroscopic al leziunilor

În timpul examenului endoscopic realizat la pacienții incluşi în studiu s-au putut observa următoarele leziuni macroscopice ale peretelui bronşiilor şi ale mucoasei acestora:

a) modificări ale calibrului bronşiilor:

- îngustarea orificiilor bronşiilor lobare (n= 1);
- diminuarea diametrului bronşiilor principale secundară îngroşării mucoasei bronşice (n= 9) (fig. 2);
- diminuarea până la ştergere a reliefului cartilaginos (n= 7);
- rotunjirea pintenilor bronşiilor lobare şi segmentare, cu aspect lucios (n=8);
- diminuarea diametrului bronşiilor principale secundară îngroşării mucoasei bronşice, cu aspect fascicular longitudinal la nivelul peretelui posterior (n=1) (fig. 3).

b) leziuni ale mucoasei bronşice:

- hiperemie, de aceeaşi intensitate pe toată suprafața examinată (n=18) (fig. 4);

Fig. 2. Îngroşări neregulate, difuze ale mucoasei bronşice – astm bronşic moderat persistent

Fig. 3. Îngroşarea mucoasei bronşice, cu aspect fascicular longitudinal, la nivelul peretelui posterior – astm bronşic moderat persistent

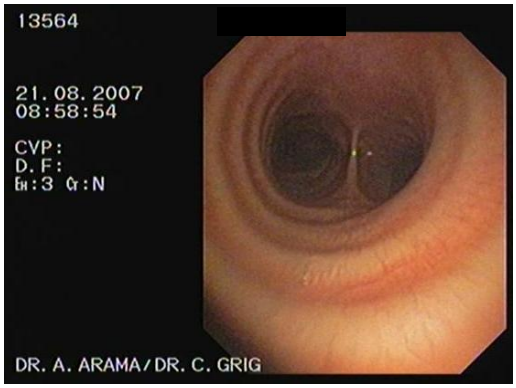

Fig. 4. Mucoasă bronşică cu hiperemie cu aceeaşi intensitate pe întreaga suprafaţă – astm bronşic uşor persistent

Fig. 5. Atrofie mucoasă bronşică – astm bronşic uşor persistent

- aspect lucios şi neted a mucoasei peretelui bronşic secundar edemului acesteia (n=13);
- atrofia mucoasei bronşice (n=3) (fig. 5);

c) alte modificări endoscopice:

- prezenţa în căile aeriene a unui mucus vâscos în cantitate variabilă (n=19) (fig. 6);
- diskinezie hipotonă (colabare în expir) a pereţilor bronşici (n=2).

La un număr de 7 pacienţi, mucoasa bronşică a prezentat un aspect macroscopic cvasinormal.

Fig. 6. *Mucus vâscos, edem şi congestia mucoasei – astm bronşic moderat persistent*

Profilul microscopic al leziunilor

Examenului microscopic al fragmentelor de mucoasă bronşică realizat la pacienţii incluşi în studiu a permis observarea următoarelor leziuni microscopice:

a) leziuni ale epiteliului mucoasei bronşice:

- denudare epitelială totală (n=21);
- denudare epitelială parţială (n=15) (fig. 7);
- hiperplazia celulelor caliciforme (n= 36) (fig. 8);
- leziuni de metaplazie scuamoasă (n= 16).

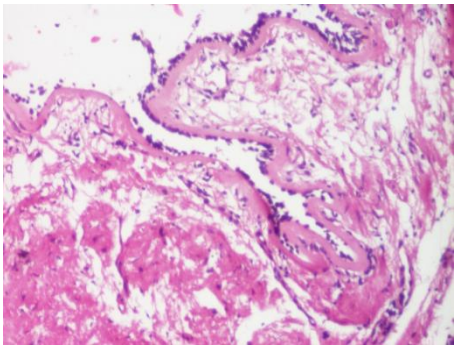

Fig. 7. *Denudare epitelială parţială – astm bronşic sever persistent, H.E. x100*

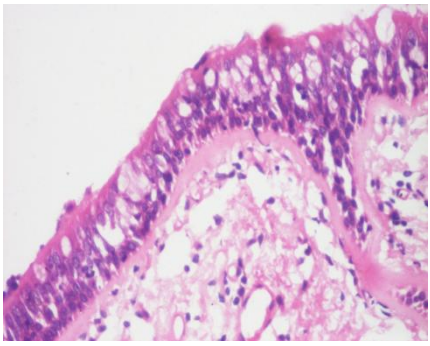

Fig. 8. *Hiperplazie a celulelor caliciforme – astm bronşic uşor persistent, H.E. x 200*

b) leziuni ale membranei bazale a epiteliului mucoasei bronşice

- îngroşarea membranei bazale a epiteliului respirator (fig. 9), mai importantă la pacienţii cu forme sever persistente de astm - comparativ cu pacienţii care au fost încadraţi în stadiile intermitente şi uşoare de boală.

c) leziuni ale laminei propria (corionului):

- edemul mucoasei bronşice (n=38);
- creşterea numărului de vase la nivelul laminei propria la toţi pacienţii incluşi în lot (n=38);
- hipertrofie musculară (n=20) (fig. 10);
- hipertrofie glandulară (n=20);
- prezenţa unui infiltrat inflamator polimorf în cantitate variabilă (n=38) în raport cu severitatea bolii astmatice.

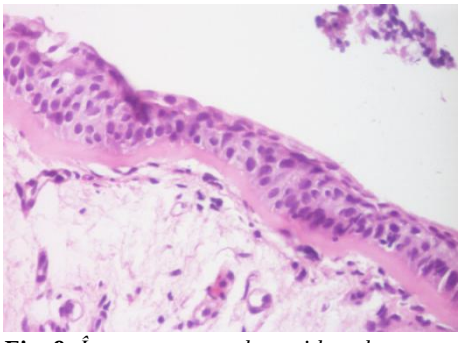

Fig. 9. *Îngroşarea membranei bazale – astm bronşic uşor persistent, H.E. x 200*

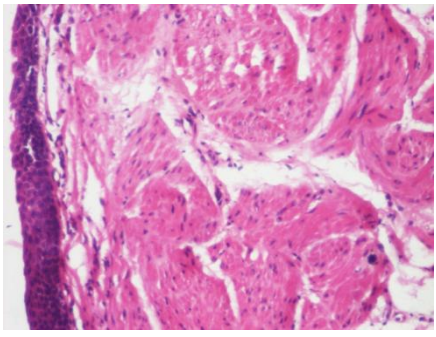

Fig. 10. *Hipertrofie musculară - astm bronşic sever persistent, H.E. x 100*

DISCUŢII

Prevalenţa bolii astmatice a crescut semnificativ din anii 70, în 2009 raportându-se, la nivel mondial, aproximativ 300 milioane de astmatici. Mai mult, deşi metodele de diagnostic şi de tratament s-au îmbunătăţit semnificativ în ultimii ani, în cursul anului 2009 astmul bronşic a determinat peste 250 000 de decese în întreaga lume (12,13).

Examenul fibrobronhoscopic nu constituie o metoda curentă de investigaţie in astmul bronhic. Utilitatea metodei este restrânsă la diagnosticul diferenţial al obstrucţiilor bronşice determinate de neoplazii sau de corpi străini endobronşici (2,8).

Prima etapă în cuantificarea leziunilor peretelui bronşic este examinarea directă a suprafeţei mucoasei bronşice, în cursul examenului fibrobronhoscopic, permiţând vizualizarea bronşiilor de calibru mare şi mediu (în general până la nivelul bronşiilor subsegmentare) (2). Teritoriile distale, aflate dincolo de limita abordului endoscopic direct, sunt explorate prin lavaj bronhoalveolar care permite analiza compoziţiei celulare totale şi/sau parţiale precum şi a mediatorilor inflamaţiei (14).

Examenul macroscopic realizat în cursul fibrobronhoscopiei aduce date importante în aprecierea gradului inflamaţiei bronşice, care se corelează macroscopic cu edemul şi congestia mucoasei (1). În lotul studiat, hiperemia şi edemul mucoasei au fost modificări frecvent observate şi anume la 18 pacienţi (47,36%) şi respectiv la 13 pacienţi (34,21%) din totalul celor examinaţi. La apariţia acestor modificări macroscopice participă congestia şi angiogeneza prezente la nivelul mucoasei bronşice (6,15). Edemul mucoasei bronşice determină şi ştergerea reliefurilor cartilaginoase, aspect remarcat şi la 7 pacienţi din lotul examinat (18,42%).

Îngroşarea mucoasei bronşice conduce la reducerea diametrului acesteia, leziune observată la 9 pacienţi din cazuistică (23,68%), fiind constantă, comparativ cu leziunile de atrofie a mucoasei bronşice, semnalate doar în 3 cazuri (7,89%). În determinismul atrofiei mucoasei intervine în mod adjuvant terapia cronică steroidiană (6).

Hipersecreţia de mucus observată endoscopic se corelează cu hiperplazia celulelor caliciforme din structura epiteliului respirator şi a glandelor din submucoasă, cu intensitate variabilă în funcţie de cu severitatea bolii astmatice (16, 17). Macroscopic, în cazuistica de faţă, s-a constatat prezenţa în căile aeriene a unui mucus vâscos, în cantitate variabilă la 19 pacienţii (50%). Reducerea diametrului bronşiilor se datorează în parte edemului care duce la îngroşarea mucoasei şi fenomenului de ,,remodelare a peretelui bronşic" care apare în evoluţia bolii astmatice (18). Acest proces ireversibil este caracterizat şi prin leziuni de hiperplazie/hipertrofie musculară şi hiperplazie glandulară (18).

Se consideră astăzi că apariţia leziunilor epiteliale stau la baza dezvoltării unui proces inflamator cronic al mucoasei, element care contribuie suplimentar la întreţinerea modificărilor epiteliale (19,20). Denudarea epitelială apare ca o reacţie epitelială la agresivitatea inflamaţie de la nivelul mucoasei, deşi există studii în literatura de specialitate care sugerează ideea că aspectele de denudare epitelială remarcate la examenul microscopic în astmul bronşic s-ar datora, în parte, şi tehnicilor de recoltare fibrobronho-scopică (21). În studiul de faţă au fost observate leziuni de denudare epitelială parţială (15 cazuri - 39,47%), precum şi leziuni de denudare epitelială totală, acestea din urmă fiind notate la 21 de cazuri (55,26%) din totalul celor examinate.

O altă modalitate de răspuns a epiteliului respirator faţă de procesul inflamator cronic este şi apariţia hiperplaziei de celule

caliciforme, precum şi a unor arii mai mult sau mai puțin extinse de metaplazie scuamoasă. Hiperplazia celulelor caliciforme are grade diferite de severitate, acesta stând la baza hipersecreție de mucus care caracterizează boala astmatică (22). În cadrul lotului studiat, hiperplazia caliciformă a fost o leziune epitelială frecvent notată (36 de cazuri – 94,73%), în timp ce metaplazia scuamoasă a fost mai rar observată (la 16 de pacienți - 42,10%%).

Îngroşarea membranei bazele a epiteliului respirator este leziunea microscopică ce caracterizează boala astmatică în cadrul bronhopatiilor obstructive. Studiile din literatura de specialitate descriu îngroşarea membranei bazale ca şi modificare constantă la toți pacienții astmatici (23,24). Mai mult, grosimea membranei bazale este în concordanță cu treapta de severitate a bolii (25). Această leziune a fost notată la toți pacienții (38 de cazuri – 100%) incluşi în lot, o îngroşare importantă a membranei bazale fiind observată la persoanele cu forme sever persistente de boală.

Leziunile epiteliale descrise mai sus sunt acompaniate de existența unui infiltrat inflamator polimorf în lamina propria. Intensitatea şi stabilirea compoziției celulare pentru infiltratul inflamator a constituit obiectul de studiu a numeroase cercetări de specialitate (26,27). Prezența acestuia la nivelul mucoasei bronşice determină apariția edemului şi a hipervascularizației, elemente care contribuie la îngroşarea mucoasei bronşice (28,29). În acest proces intervine şi hipertrofia musculară şi glandulară - leziuni remarcate mai ales în formele severe de boală (astm moderat şi sever persistent) (30,31).

Rezultatele examenului microscopic pe lotul evaluat concordă cu datele din literatură, leziuni precum edemul, hiper-vascularizația şi infiltrarea inflamatorie a mucoasei bronşice fiind observate la toți pacienții (38 de cazuri – 100%) din cazuistică. Hipertrofia musculară şi cea glandulară au fost remarcate la 20 dintre pacienți (52,63%), aceştia fiind încadrați în stadiile moderat persistent şi respectiv sever persistent de boală.

CONCLUZII

Fibrobronhoscopia reprezintă cea mai importantă metodă de explorare endoscopică a căilor aeriene. Deoarece aceasta metodă invazivă necesită doar anestezie locală, toleranța pacientului este bună şi riscurile minime, fibrobronhoscopia a devenit astăzi metoda de elecție pentru susținerea diagnosticului în patologia pulmonară. Examenul macroscopic fibrobronhoscopic aduce date importante în ceea ce priveşte modificările mucoasei căilor respiratorii din astmul bronşic, permițând de asemenea recoltarea de fragmente de mucoasă bronşică prin biopsie şi realizarea unui diagnostic diferențial corect. Totuşi, biopsia bronşică rămâne „gold standard''- ul în ceea ce priveşte evaluarea inflamației mucoasei şi a procesului de ,,remodelare" a peretelui bronşic din evoluția bolii astmatice.

PYRIDINE-DERIVED SCHIFF BASE-ANALYTICAL REAGENT FOR IRON (II) IONS (Abstract): **Aim**: Development of a new spectrophotometric method for quantitative determination of Fe (II) ions in pharmaceutical products based on the complexation reaction of the cations with an original Schiff base-2-salicylidene-aminopyridine, when a red complex, extractable in chloroform, with a maximum absorption at 525 nm has formed. **Material and methods:** A UV-VIS Hewlett-Packard 8453 Spectrophotometer has been used for all determinations. The optimum working conditions of the complexation reaction have been established by studying the influence of pH, ionic strength, and combining ratio on the complexation reaction. **Results:** The calibration curve had been plotted, and the detection limit was determined (L_D=1 μg). The proposed method has a good linearity in the 5-50 μg/mL range with a correlation coefficient r = 0.9946. The stability constant and the molar extinction coefficient were calculated ($\varepsilon = 4.16 \cdot 10^4$ $mol^{-1} \cdot L \cdot cm^{-1}$). The cation-ligand ratio was 1:2. The complexation reaction of Fe (II) ions with the Schiff base had no cation interferers, not even Fe (III) ions. **Conclusions:** The proposed method has been applied for the determination of Fe (II) in pharmaceutical products with very good results. **Keywords:** SCHIFF BASE, IRON (II) IONS, SPECTROPHOTOMETRY.

Iron is an essential element for living organisms, as it is involved in the transport of oxygen and in cellular oxidative processes. It is found in amounts of 5 mg/kg bodyweight for men and 30 mg/kg bodyweight for women. Approximately 2/3 of all iron ions are found in circulating red blood cells in the composition of hemoglobin, while smaller percentage may be found in myoglobin (4%), hemic enzymes (0.2%), transferrin (0.12%) and about 25% is deposited as ferritin and hemosiderin. Depending on the way iron they are bound, iron-protein complexes can be classified into three groups: hemoproteins, iron-sulfur proteins and iron-proteins. In hemoproteins, iron is incorporated into a system of four tetrapyrrole rings linked to proteins, such as myoglobin, hemoglobin, cytochrome c and enzymes such as cytochromoxidase, catalase and peroxidases. The binding of Fe to proteins occurs at certain sites of amino acids (1-4).

Schiff bases are a sub-class of imines. They are common enzymatic intermediates. During physiological processes involving pyridoxal-5'-phosphate, intermediate Schiff bases form between the α-NH_2 group of L-

valine, the ε-NH_2 group of lysine and the protein chains (5). In aqueous medium at pH = 4.5-8.5, fluorescent Schiff bases of 5'-dioxipyridoxal with n-hexylamines, are formed (6). In the synthesis of temperature-dependent tryptophan and the pH of the medium, an intermediate ligand is formed which is a Schiff base, pyridoxal-5'-phosphate-L-serine (7). There are also Schiff bases that exhibit electrical and magnetic properties (8).

The Schiff bases can be used as analytical reagents for the quantitative determination of important cations in the body (9). We have performed an analytical study on a Schiff base: 2-salicylidene-amino pyridine (fig. 1). It is an organic ligand obtained through the reaction of salicylaldehyde with 2-aminopyridine (10, 11).

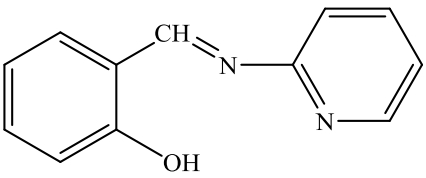

Fig. 1. 2-salicylidene-aminopyridine

The paper presents the development and validation of a new spectrophotometric method for the quantitative determination of Fe (II) ions and its application for the analysis of pharmaceutical products.

MATERIAL AND METHODS

A UV-VIS Hewlett-Packard 8453 spectrophotometer has been used for all determinations. All reagents and solvents were analytical grade.

A 0.1 mg/mL Fe (II) stock solution was prepared in distilled water, and then by suitable dilutions a 5-50 μg/mL Fe (II) standard solution was obtained. Reagent solution 0.1% (w/v) was prepared by dissolving 2-salicylidene-amino pyridine (SB) in methanol. A 0.2M sodium acetate and acetic acid buffer solution with pH = 5.6 has been used.

The Fe (II) ions react with 2-salicylidene-amino pyridine (SB) at pH = 6.0, and a complex combination is formed. It is extracted in chloroform and its absorbance measured at 525 nm is proportional to the concentration of the cations.

The optimum wavelength for detection was selected and the optimum working conditions were established by studying the influence of pH, formation time, and the stability of the complex (12, 13).

The cation/ligand combination ratio, the stability conditional constant (βn), and the limit of detection were calculated, and the potential interferers have been evaluated.

The complexation reaction was influenced by the ionic strength of the solution. Thus, the concentration and volume of the KCl solution that provided the ionic strength that maximized the absorption must be established. 1 mL of 30 μg/mL Fe(II) standard solution was treated at pH = 5.6 (0.2M sodium acetate and acetic acid buffer solution)with 0.5 mL solution with various concentration levels of KCl, 1 mL 1% (w/v) SB reagent solution. After extraction in 5 mL $CHCl_3$ and separation, anhydrous sodium sulfate was used to remove any traces of water, and the absorbance of the organic layer was measured at λ = 525 nm against a blank sample.

The complexation reaction was influenced also by the pH of the solution. So 1 mL of 30 μg/mL Fe(II) standard solution was mixed with 1 mL sodium acetate and acetic acid buffer solutions with a pH that varied in the range 3.5-7.0. 0.5 mL KCl solution $2.5 \cdot 10^{-2}$ M and 1 mL 1% (w/v) SB reagent solution. After the extraction of the

red complex in 5 mL $CHCl_3$ and separation, anhydrous sodium sulfate was used as desiccant, and the absorbance of the organic layer was measured at λ = 525 nm against a blank sample.

The influence of the number of extractions in chloroform of the complex combination on its absorbance was evaluated by comparing the results obtained when using 5 mL of organic solvent once versus using 2.5 mL of chloroform twice.

The metal-ligand combination ratio was determined using various volumes of Fe (II) standard solution and mixing then with SB reagent solution with various concentration levels ($7 \cdot 10^{-3}$ M; $5 \cdot 10^{-3}$ M; 10^{-2} M), thus achieving the following combination ratios: 0.2, 0.3, 0.5, 0.7, 1.0, 1.5, 2.0, and 3.0. The mixtures were processed as previously described.

The stability constant (K_s) - expressed as $L \cdot cm^{-1} \cdot mol^{-1}$ - of the complex combination was determined using Harvey-Manning dissociation method based on the instability constant (K_i), according to the following equations (14):

$$K_s = 1/K_i$$

$$K_i = \frac{\alpha^2 C}{1-\alpha} \quad \text{and} \quad \alpha = \frac{A_m - A}{A_m}$$

where: α = degree of dissociation, A_m = maximum absorbance, A = equilibrium absorbance, c = molar concentration of Fe (II).

A second method for calculating the stability constant (β_n) was based on the following equation (15):

$$\beta_n = \frac{A/A_m}{(1-A/A_m)n^2 C_L^n}$$

where: Am = maximum absorbance,
A = equilibrium absorbance,
n = the coordination number of the ligand, and C_L = molar concentration of the ligand.

The new spectrophotometric method was validated and applied for the quantitative determination of Fe (II) (16-21).

RESULTS AND DISCUSSION

The optimum pH value for the complexation was established to be 5.6 (fig. 2). It was achieved using a 0.2 M acetic acid-sodium acetate buffer solution.

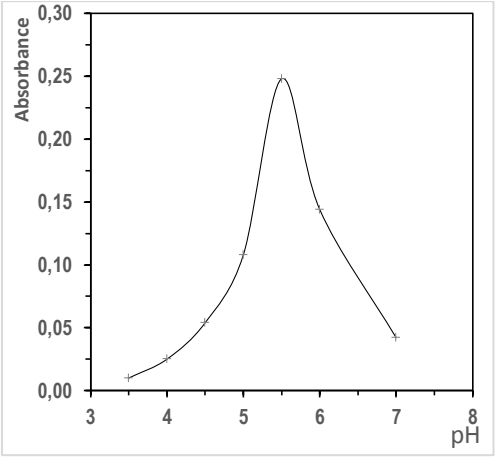

Fig. 2. Influence of pH on the absorbance of the SB-Fe (II) complex

The concentration and volume of the KCl solution providing the ionic strength for maximum absorbance of the complex was established based on the results shown in table I. It was established that a volume of 0.5 mL of KCl $2.5 \cdot 10^{-2}$ M solution provided a μ = 0.005526 ionic strength and maximum absorbance.

The results of the study on the variation of absorbance according to the number of extractions are shown in table II, and they prove that one extraction was found to be effective.

TABLE I

Influence of ionic strength on absorbance

Fe(II) (μg/mL)	KCl concentration	1% SB reagent solution (mL)	$CHCl_3$ (mL)	A 525 nm
30	$7.5 \cdot 10^{-1}$ M	1	5	0.140
30	$5 \cdot 10^{-1}$ M	1	5	0.147
30	$2.5 \cdot 10^{-1}$ M	1	5	0.155
30	10^{-1} M	1	5	0.167
30	$2.5 \cdot 10^{-2}$ M	1	5	0.248

TABLE II

Absorbance variation depending on the number of extractions

Fe(II) (μg/mL)	Buffer solution pH = 5.6 (mL)	$2.5 \cdot 10^{-2}$M KCl (mL)	1% SB reagent solution (mL)	$CHCl_3$ (mL)	A 525 nm
30	2.5	0.5	1	5.0	0.250
30	2.5	0.5	1	2.5 × 2	0.248

TABLE III

Absorbance variation depending on the number of extractions

Fe (II):SB Combination ratio	A 525 nm		
	$5 \cdot 10^{-3}$ M Fe (II)	$7.5 \cdot 10^{-3}$ M Fe (II)	$5 \cdot 10^{-2}$ M Fe (II)
1:5	0.169	0.294	0.578
1:3	0.200	0.323	0.702
1:2	0.212	0.391	0.869
1:1.4	0.177	0.315	0.777
1:1	0.092	0.285	0.653
1:0.66	0.069	0.219	0.546

Based on the data obtained (tab. III) the ion: ligand combination ratio was plotted, and its value was 1:2.

Determination of complex stability constant was done using the graph method in order to determine the values for the maximum absorbance (Am = 0.890) and the equilibrium absorbance (A = 0.292), and then to calculate the instability constant of the complex $K_i = 7.3 \cdot 10^{-5}$ and the stability constants $K_s = 1.4 \cdot 10^4$, considering that n = 2, and the concentration of the Fe (II) was 10^{-2} M. The calculated value of the extinction molar coefficient was $4.16 \cdot 10^4$ $mol^{-1} \cdot L \cdot cm^{-1}$. The second method of calculating the stability constant produced results ($\beta_n = 1.5 \cdot 10^4$ and $1.45 \cdot 10^4$) which were very close to those obtained using the Harvey-Manning dissociation method.

The optimized procedure was: 1 mL Fe(II) standard solutions (5-50 μg/mL) were mixed with 2.5 mL sodium acetate and acetic acid 0.2M pH = 5.6 buffer solution, 0.5 mL KCl solution $2.5 \cdot 10^{-2}$ M and 1

mL 1% (w/v) SB reagent solution. After one extraction of the red complex in 5 mL $CHCl_3$ and separation, anhydrous sodium sulfate was used as desiccant, and the absorbance of the organic layer was measured after 10 minutes at 525 nm against a blank sample in a 1 cm cuvette.

During the validation of the method, it was established that the absorbance was proportional to the concentration in Fe (II) and the Lambert-Beer Law was obeyed in the 5-50 μg/mL range, with a correlation coefficient of 0.9946. The calibration curve is presented in fig. 3 and the linear equation was: $A = 0.008877 \cdot c - 0.02547$ (correlation coefficient = 0.9946, intercept = 0.008877, slope = 0.02547).

Table IV includes the results of the statistical data processed during the validation of the VIS spectrophotometric method for the quantitative determination of Fe (II).

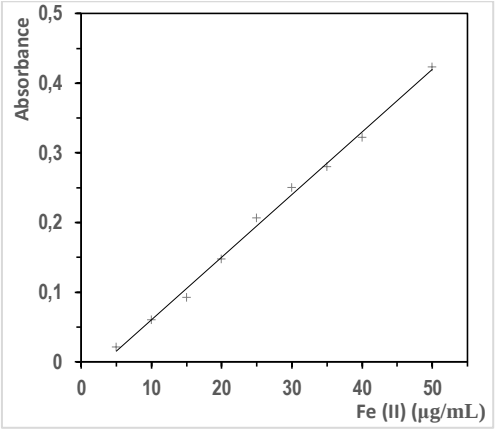

Fig. 3. Calibration curve

TABLE IV

Validation parameters

5	5.18	98.95	Linearity range: 5.18-50.74 μg/mL Fe(II) Intercept = 0.008877·and slope = 0.02547 r = 0.9972; SD = 0.91 Accuracy: 98.94±1.009 n = 18; t_α = 2.11; α = 0.95 Repeatability: CV_r = 0.92 (n = 9) Reproducibility: CV_R = 2.05 (n = 18)
10	9.62		
15	13.23		
20	19.42		
25	26.00		
30	31.19		
35	34.21		
40	39.14		
50	50.74		

There were studies conducted that proved that the complexation reaction of Fe (II) using the Schiff base was not interfered by any other cation. The interference of Fe (III) on the complexation reaction at pH = 5.6 in the presence of KCl ($2.5 \cdot 10^{-2}$ M) has also been ruled out. The method could still be used for the indirect quantitative determination of Fe (III) after the reduction reaction to Fe (II) using reduction agents such as hydroxylamine or ascorbic acid.

The spectrophotometric determination method for Fe (II) using the Schiff base as reagent has been applied with very good results for the analysis of an antianemic pharmaceutical product formulated as syrup (tab. V).

The following procedure had been used: 2.5 mL syrup sample (7.2 mg/mL Fe (II)) was diluted with distilled water into a 100 mL graduated flask. 1 mL diluted sample solution was diluted even further with dis-

tilled water using a 10 mL graduated flask. 1 mL of solution was mixed with 0.5 mL sodium acetate and acetic acid 0.2M pH = 5.6 buffer solution, 0.5 mL KCl solution $2.5 \cdot 10^{-2}$ M and 1 mL 1% (w/v) SB reagent solution. After one extraction of the red complex in 5 mL $CHCl_3$ and separation, anhydrous sodium sulfate was used as desiccant, and the absorbance of the organic layer was measured after 10 minutes at 525 nm against a blank sample in a 1 cm cuvette.

TABLE V

Applications of the spectrophotometric method for Fe (II)

Labelled Fe(II) (mg/5mL)	Analyzed Fe(II) (mg/5mL)	Recovery (%)	Statistical parameters	
			Repeatability	Reproducibility
36	36.3794	101.05	n = 5 M = 36.3342 S = 0.1883 S_x = 0.0842 A = 36.3342±0.2341 CV_r = 0.5184%	n = 15 t_α = 2.15 α = 0.95 M = 36.31 S = 0.34 A = 36.31±0.188 CV_R = 0.93
36	36.6046	101.67		
36	36.1541	100.42		
36	36.3794	101.05		
36	36.1541	100.42		
FRX Criteria: 34.92-37.12 mg/5mL				

The method proved to be as accurate if not more as other spectrophotometric methods, while using a simple procedure (22-23).

CONCLUSIONS

We proposed a new spectrophotometric method for the determination of Fe (II) in antianemia pharmaceutical products, based on our study on the complexation reaction of those cations with 2-salicylidene aminopyridine. The Schiff base that was used as reagent, formed with Fe (II) at pH = 5.6 a red complex extractible in chloroform with a maximum absorption at λ = 525 nm. The Lambert-Beer Law was obeyed in the concentration range 5-50 μg/mL Fe (II), and the linearity coefficient was r = 0.9946. The statistical parameters highlighted the good precision of the spectrophotometric method. The optimization of the method included: a study of pH and ionic strength influence on the complexation reaction, calculus of the combination ratio, stability constant and molar extinction coefficient, plotting the calibration curve, establishing the detection limit, and the evaluation of interferers. The statistical parameters highlighted the accuracy of the method, with relative errors well within the limit of criteria for VIS spectrophotometric methods. The method has been applied successfully for the analysis of iron (II) ions in antianemia pharmaceutical products, and it could be also used for the indirect analysis of iron (III) ions.

PUBLIC HEALTH IN ORHEI COUNTY – REALITIES AND OPPORTUNITIES (Abstract): Orhei District Hospital has 420 beds located in 17 wards. Providing beds in 2010 is 39.2 to 10 000 people compared with 47.7 in 2008, but it is still more than the regional average for the country- 32.6. Rotation bed, the lethality rate of hospitalization of people have not changed in the previous year. The average duration of treatment and average bed occupancy rose in 2010 compared with 2009, but the bed occupancy rate is still small - about 60%.Share divergence diagnostic is lower than the previous year - this is a good indicator of quality. Enough old equipment is still an issue for the District Hospital Orhei. Making an analysis of the distinctive features of health care evaluations, where resources are expressed by the cost and the results are expressed as effects on health, we conclude that it is necessary to change the conceptual aspects regarding health care financing. For redress the economic and financial situation, is proposed following strategy: 1. Reduced costs for hotel accommodation, by introducing "a day hospital". This system implies investigation and medical advice, and writing medication without the patient to remain hospitalized for a long time (for cases that do not require prolonged hospitalization) 2. Reducing costs the necessary material resources with, the introduction of electronic auction. 3. Introducing the concept of health management, need for hospital management, better management the four types of resources available (human resources, material resources, financial resources, time). 4. Increasing managerial capacity, through a competitive selection manager, will be combine short-term planning and the long-term strategy (more flexible) to raise the efficiency of medical care. In this respect spaces allocated section of Pulmonology, will be reassembled in geriatric beds, and the space available, will be outsourced of other persons (individuals or corporate person), under the law where they will earn additional income. It is noted that the actual development costs are increasing. **Key words**: PUBLIC HEALTH, HOSPITAL, QUALITY OF MEDICAL CARE.

Conform legii, una din activităţile importante ale administraţiei raionului Orhei este asigurarea sănătăţii în conformitate cu necesităţile populaţiei şi prestarea serviciilor pentru maladiile prioritare în limita resurselor disponibile (2,5). Primul pas în atigerea acestui scop este evaluarea situaţiei referitor la starea sănătăţii populaţiei şi serviciile medicale existente la nivel local (raion Orhei).

SCOPUL LUCRĂRII

Sistemul public de servicii de sănătate existent în Raionul Orhei, Republica Moldova este necesar de a fi îmbunătăţit şi de asemenea se impune implementarea de noi servicii

axate pe problemele prioritare de sănătate ale populaţiei deservite. Pacienţilor trebuie să li se ofere o posibilităţi de alegere mai mari astfel încât fiecare pacient să aibă acces de fiecare dată la cea mai bună îngrijire. Calitatea înaltă a serviciilor de sănătate este posibilă doar atunci când fiecare membru al instituţiei şi fiecare parte a sistemului de sănătate lucrează eficient şi în armonie cu restul. Deasemenea trebuie să ne asigurăm că acţiunile întreprinse să fie orientate spre pacient şi să vedem serviciile oferite din perspectiva pacientului.

Identificare problemelor şi neajunsurilor activităţii instituţiilor prestatoare de servicii de sănătate este primul pas în demersul de creştere a calităţii acestora.

MATERIAL ŞI METODĂ

Acest studiu s-a realizat pe baza rezultatelor analizei activităţii medicale şi economice a instituţiilor medicale publice din raionul Orhei în perioada 2009-2010. Aceste rezultate au fost coroborate cu datele statistice oficiale oferite de Centrul de Statistică a raionului Orhei, indicatorii demografici calculaţi de Biroul Stării Civile Orhei, datele activităţii financiare oferite de CNAM, indicatorii stării de sănătate a populaţiei prezentaţi de Centrul Medicilor de Familie (CMF) Orhei, planurile de afaceri ale instituţiilor medicale, rapoartele rulajului materialelor şi produselor farmaceutice, statistica şi politica de resurse umane.

Datele au fost sistematizate şi analizate după cum urmează : indicatorii demografici (1) şi socio-economici ; indicatorii stării de sănătate ; indicatorii sistemului de sănătate ; finanţarea serviciilor medicale la nivel regional.

REZULTATE

Raionul Orhei are o suprafaţă de circa 120 mii hectare. Populaţia raionului este de 127,824 mii locuitori (dintre care 30 536 copii şi 97 288 adulţi).

Ponderea populaţiei 0-14 ani este mai mică decât ponderea populaţiei în vârstă (50 ani şi peste), respectiv 17,6% şi 25,3%.

Situaţia din perioada anilor 1995–2009 a arătat o reducere a ratei natalităţii în regiune de la 19,9‰ în 1995 la 10,3‰ în 2009. Numărul total al femeilor de vârstă fertilă este 36 247, rata generală a fertilităţii fiind de 26,7 la 1000 femei de vârstă reproductivă.

Din numărul total de persoane decedate, 15,3‰ constitue populaţia aptă de muncă. Mortalitatea infantilă în raionul Orhei este mai mică decât cea la nivel naţional (respectiv 10,8‰ şi 12,4‰).

Morbiditatea generală a populaţiei este prezentată sintetic în fig. 1.

În structura prevalenţei pe primul loc se situează Maladiile aparatului circulator– 102,7 la 10 000 populaţie ; II loc– Maladiile aparatului digestiv– 882,8 şi locul III– Tulburările mentale şi de comportament– 579,2 la 10 000 populaţie (tab. 1).

Prevalenţa alcoolismului în raionul Orhei este mult mai mare decât cea de la nivel naţional (2046,8 şi respectiv 1292,0 la 100 000 populaţie).

În acelaşi timp narcomania a înregistrat o creştere în rata de prevalenţă (circa de 2 ori), dar incidenţa (cazurile noi) a scăzut.

Pe parcursul anului 2010 au fost încadraţi în grad de invaliditate 361 persoane, ceea ce este cu 3 persoane mai puţin decât în 2009, mai mult de jumătate dintre acestea– 51,5% au primit gradul II de invaliditate şi fiecare a treia persoană– gradul III.

Invaliditatea copiilor sub 16 ani a scăzut în 2010 comparativ cu anul 2009 (19,42 şi respectiv 23,03 la 1 000 copii) : gradul I– 33%, gradul II– 59,6% şi gradul III– 8,9%). Pe locul întâi sunt tulburările mentale şi de comportament– 29,9%, majoritatea fiind reprezentată de cazurile de retard mental şi epilepsie. Pe locul doi sunt malformaţiile congenitale– 23%, iar pe locul trei sunt maladiile sistemului nervos– 18,0%.

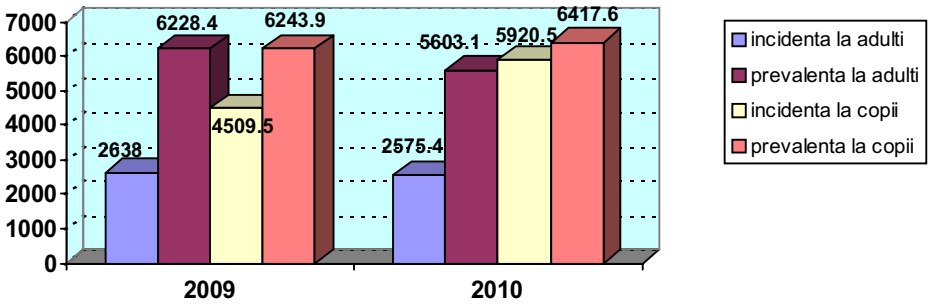

Fig. 1. Morbiditatea populaţiei (la 10 000 populaţie)

TABELUL 1

Incidenţa şi prevalenţa pentru primele cinci cauze de îmbolnăvire *(adulţi)*

	Prevalența					
Anul	**2009**			**2010**		
Locul în structură	Nosologia	la 10 000 populație	% din total	Nosologia	la 10 000 populație	% din total
I	Maladiile aparatului circulator	1041,46	16,7	Maladiile aparatului circulator	1102,7	19,6
II	Maladiile aparatului digestiv	874,18	14,0	Maladiile aparatului digestiv	888,8	15,8
III	Maladiile aparatului respirator	589,2	9,5	Tulburări mentale şi de comportament	579,2	10,3
IV	Maladiile aparatului genito-urinar	584,05	8,8	Maladiile aparatului respirator	569,2	10,2
V	Tulburări mentale şi de comportament	546,19	8,7	Maladiile aparatului genito-urinar	506,9	9,0
	Incidența					
	Nosologia	la 10 000 populație	% din total	Nosologia	la 10 000 populație	% din total
I	Maladiile aparatului respirator	440,12	16,7	Maladiile aparatului respirator	426,8	16,5
II	Maladiile aparatului genito-urinar	286,93	10,8	Maladiile aparatului circulator	255,2	9,9
III	Maladiile aparatului circulator	213,17	8,0	Maladiile aparatului genito-urinar	253,8	9,3
IV	Maladiile aparatului osteo-muscular şi ale ţesutului conjunctiv	210,39	7,9	Graviditate, naştere şi puerperium	227,5	8,8

În raionul Orhei, personalul care activează în sistemul public de sănătate constă în 1139 angajaţi : 185 medici, 581 asistente medicale, 237 infermiere, 136 angajaţi auxiliari.

Asigurarea cu medici de familie a populaţiei din raionul Orhei este mai mică decât la nivel naţional (4,8 comparativ cu 5,7 la 10 000 populaţie) (tab. 2).

Centrul Medicilor de Familie (CMF) Orhei, parte componentă a Spitalului Raional Orhei, deserveşte populaţia prin intermediul a 18 Centre de Sănătate, 30 Oficii ale Medicilor de Familie şi 17 filiale ale Oficiilor Me-

dicilor de Familie. Din totalul de 64 de centre medicale– 46 sunt amplasate în clădiri corespunzătoare (71,8%); 27 (42%) necesită reparaţii curente; 4 (6%) necesită reparaţii capitale.

Numărul total de consultaţii efectuate de medicii de familie a crescut de la 272 895 în 2009 la 333 625 în 2010, iar valoarea medie a numărului de consultaţii/locuitor de la 2,09 în 2009 la 2,57 în 2010. Cea mai mare pondere revine populaţiei de până la 18 ani de la 2,83 în anul 2009 la 3,91 consultaţii/locuitor în 2010.

În anul 2010 au fost luate la evidenţă 1 252 gravide. Ponderea gravidelor luate la evidenţă până la 12 săptămâni de sarcină are o tendinţă de creştere de la 71,1% în 2009 la 78,8% în 2010. În acelaşi timp, ponderea anemiei la gravide este încă mare– 56%, cu toate că conform Programului Unic sunt prescrise gratuit preparate de fier pentru gravide. Ponderea patologiilor extragenitale la gravide este încă mare (114,2 la 1 000 gravide în Orhei comparativ cu 65,5% la nivel naţional). 75% dintre gravide au fost examinate USG la 18-21 săptămâni, mai mult decât în 2009– 71,6% şi în 2008– 66,6%. 99% din gravide au fost consultate de ginecolog ceea ce se consideră un indicator bun. 96,5% naşteri au fost la termen şi 3,5%- prematur. Ponderea avorturilor a constituit 60,4/ 100 născuţi vii în 2009, ceea ce este mai mult decât în 2008– 55,0 şi mai mult decât la nivel naţional– 40,8. În anul 2010 au fost înregistrate 20 cazuri de naşteri la domiciliu. *Stillbirth rate* este mai mică decât la nivel naţional (respectiv 4,6‰ comparativ cu 5,8‰) şi a scăzut în 2010 comparativ cu anul precedent. Mortalitatea perinatală este mai mică decât la nivel naţional (8,1‰ şi respectiv 11,5‰), dar este puţin mai mare decât în anul 2008 (7,5‰).

Asistenţa Medicală Urgentă în raionul Orhei este asigurată de 7 echipe medicale: 4 cu profil general, 1 specializată pentru copii, 1 cardiologică şi o echipă de asistenţi medicali. Rata solicitărilor/ 1 000 populaţie rurală a crescut de la 232,3 în 2009 la 313,3 în 2010.

Asistenţa Medicală Specializată de Ambulator este asigurată de 29 medici şi 33 asistente medicale. Numărul total de vizite a crescut – 110 301 în 2008, 160 685 în 2009 şi 181 077 în 2010.

În 2010, din cheltuielile totale reale ale asistenţei medicale, 34,9% au fost pentru Sectorul primar (faţă de 31,7% în 2009), 6,9% pentru Asistenţa Medicală Specializată de Ambulator (2009–5,2%) şi 58,2% pentru Sectorul spitalicesc (2009–58,8%). S-a observat o tendinţă mică pentru redirecţionarea veniturilor şi cheltuielilor între sectoare, dar oricum Sectorul spitalicesc rămâne pe primul plan şi este încă privilegiat.

Analiza structurii cheltuielilor a relevat că în cadrul sectorului de Asistenţă Medicală Primară, 82,7% din cheltuieli au fost reprezentate de salarii şi alte sume pentru remunerarea muncii personalului medical şi plata contribuţiilor de stat (2009– 86,9%), iar pentru activităţi de investigaţii şi prestarea serviciilor de sănătate numai 5,0% (2009– 2,3%). În 2010 volumul cheltuielilor reale "per-capita"a fost 68,17 lei şi pentru populaţia asigurată– 90,47 lei, dar în acelaşi timp conform Contractului au fost stipulaţi 107,0 lei pentru persoane asigurate şi 6,0 lei pentru persoane neasigurate. Costul unei vizite este respectiv 25,79 lei şi 28,67 lei.

În Sectorul Specializat de Ambulator în 2010 remunerarea muncii şi plata contribuţiilor de stat au fost folosite la nivelul de 77,8% (2009– 75,6%) din totalul cheltuielilor. Pentru activitatea de menţinere (cheltuieli de menţinere şi gestiune)– 4,2% (2009–19,7%). Pentru consultaţiile pacienţilor şi investigaţii numai 5,0% (2009 –4,7%). Costul real al unei consultaţii pentru persoane asigurate– 12,5 lei.

Cheltuielile fixe pentru 2010 sunt în descreştere şi cheltuielile variabile sunt în creştere cu aceeaşi valoare de 8,9% com-

TABELUL 2
Numărul medicilor din Raionul Orhei

Medici	2009	2010	Asigurarea cu resurse umane
CMF/ medici de familie, a/med	69/61	72/62	72,4/70,1
Staţionar	92	84	87,1
Secţia Consultativă	26	29	87,1
TOTAL	187	185	80,6

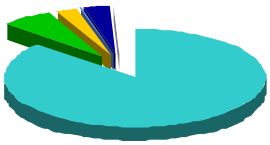

Fig. 2. Structura bugetului consolidat al IMSP spitalul Orhei

parativ cu anul 2009.

Ca şi celelalte două sectoare, Sectorul spitalicesc în 2010 a folosit majoritatea cheltuielilor pentru retribuirea muncii şi contribuţiile de stat 60,3% din cheltuielile totale (2009–56,6%), cheltuieli de menţinere şi gestiune– 15,1% (2009–18,3%), pentru hrana pacienţilor– 6,7% (2009–7,8%) şi pentru tratament- 15,8% (2009– 17,4%). Structura bugetului consolidat al IM SP spitalul Orhei este redată în fig. 2.

Costul real zi/pat este 130,33 lei (2009 – 125,80 lei) şi costul real al unui caz tratat– 1058,3 lei (2009–917,50 lei). Conform Contractului în 2010 pentru caz tratat iniţial au fost stipulaţi 990,72 lei.

Cheltuielile fixe pentru 2010 au crescut şi cheltuielile variabile au scăzut cu aceeaşi valoare de 5,0% comparativ cu anul 2009.

DISCUŢII

Raionul Orhei este cel mai mare raion din Republica Moldova. Densitatea populaţiei este de 96 persoane/m^2 ; 22% din populaţia raionului locuieşte în oraş, iar 78% în zona rurală. Oraşul Orhei este centrul administrativ şi cultural al raionului. Este situat la circa 40 km de capitală–municipiul Chişinău, şi are 29 700 locuitori. Raionul cuprinde 75 localităţi rurale, organizate în 38 primării. Ca şi majoritatea regiunilor ţării, raionul Orhei este o regiune multi-etnică. În 3 localităţi rurale majoritatea locuitorilor sunt ucraineni (3).

Structura populaţiei este mai mult de tip regresiv, deoarece ponderea populaţiei tinere (0-14 ani) este mai mică decât ponderea populaţiei în vârstă (50 ani şi peste), respectiv 17,6% şi 25,3%.

Schimbările demografice din anii precedenţi în raion, ca şi în toată ţara, sunt caracterizate prin următoarele tendinţe : scăderea natalităţii ; creşterea mortalităţii ; sporul natural negativ al populaţiei.

Principale cauzele ale mortalităţii infantile (0-1 an) sunt : unele afecţiuni din perioada perinatală–35,7% ; malformaţii congenitale, anormalii cromosomice– 21,4% şi bolile aparatului respirator– 21,4% din cazurile de deces.

Incidenţa şi prevalenţa la adulţi au scăzut comparativ cu anul 2009. În acelaşi timp, datele nu arată situaţia reală a morbidităţii generale a populaţiei, pentru că se bazează numai pe datele despre adresare.

Structura morbidităţii pe principalele cauze de îmbolnăvire a cuprins : maladiile cardiace (21,3%) ; maladiile respiratorii (20,9%) ; maladiile aparatului digestiv (11,8%) precum şi maladiile neurologice şi endocrine (11,7%). În cazul maladiilor sistemului

cardio-vascular, accidentul cerebral ocupă primul loc ca şi cauză a decesului, în aparatul digestiv– ciroza, în maldiile aparatului respirator– pneumonia.

Structura mortalităţii generale în raionul Orhei diferă de cea la nivel naţional (la nivel naţional maladiile oncologice sunt pe locul II, iar maladiile aparatului digestiv sunt pe locul III).

Analiza structurii invalidităţii a arătat că pe primul loc în structură se situează aceleaşi nosologii ca şi în structura mortalităţii şi morbidităţii. Fiecare al patrulea caz de invaliditate este cauzat de maladiile aparatului circulator, majoritatea acestor cazuri constituie maladiile hipertensive. Pe primele locuri în structura invalidităţii sunt şi maladiile aparatului digestiv, maladiile sistemului nervos, tumorile.

Consiliul Raional Orhei este fondatorul IMSP „Spitalul Raional Orhei" care prestează servicii medicale înalt calificate şi specializate pentru populaţia raionului şi raioanele adiacente: Rezina, Teleneşti şi Şoldăneşti (în special pentru asistenţa medicală specializată şi spitalicească).

Autorităţile publice locale sunt informate despre activitatea spitalului; aceasta a fost analizată trimestrial la Consiliul de Administrare. Autorităţile locale au susţinut financiar spitalul în vederea efectuării reparaţiilor şi procurării echipamentului costisitor (4).

Dacă în anul 2009 Agenţia Teritorială şi administraţia spitalului şi-au focalizat atenţia pe creştrea numărului cazurilor tratate, în 2010 atenţie deosebită s-a acordat calităţii prestaţiilor medicale, respectării standardelor, asigurării continuităţii între Asistenţa Medicală Urgentă, Asistenţa Medicală Primară, Secţia Consultativă şi Staţionar.

În anul 2010 CNAM a introdus diferenţierea în salarizarea cazurilor chirurgicale tratate operator şi medicamentos. Administraţia spitalului a propus în scris să fie luate în consideraţie cazurile tratate operator în traumatologie, obstetrică şi ginecologie cu diferenţiere de cost, însă s-a refuzat. Au fost făcute propuneri şi pentru serviciile specializate, inclusiv Centrul Perinatal, pentru raioanele alăturate ca fiind succesorul Spitalului Judeţean, dar încă nu s-a acceptat. CNAM propune reluarea acestor negocieri în primul semestru al anului 2011.

Conform *business plan*-urilor pe anii precedenţi, au crescut veniturile de la CNAM, dar conform opiniei administraţiei spitalului încă nu este suficient. De exemplu, costul medicamentelor şi costul investigaţiilor pentru o zi de spitalizare este de 22 lei. O problemă mare rămân reparaţiile curente şi procurarea echipamentului, deoarece echipamentul este foarte vechi (aproape 80% fiind uzate fizic şi moral) şi pentru creşterea calităţii serviciilor de sănătate este necesar un echipament performant şi tehnologii noi.

Analizând cheltuielile reale în 2010, observăm că ponderea cea mai mare în structura cheltuielilor în Sectorul primar şi în Sectoru specializat de ambulator revine remunerării muncii şi contribuţiilor obligatorii de stat, precum şi pentru plata serviciilor de mentenanţă, şi limitarea excesivă a cheltuielilor pentru procesul curativ şi procurarea de echipamente medicale.

CONCLUZII

1. Schimbările demografice în ultimii ani în raionul Orhei, ca şi în toată ţara, se caracterizează prin scăderea natalităţii, creşterea mortalităţii şi un spor natural negativ al populaţiei.

2. Principale cauzele ale mortalităţii generale a populaţiei în raionul Orhei sunt maladiile sistemului cardiovascular, maladiile digestive, tumorile, traumele, otrăvirile şi anumite consecinţe externe. Această structură diferă de cea la nivel naţional.

3. În 2010 s-a înregistrat o scădere a ponderii deceselor populaţiei în vârstă aptă de muncă, dar ponderea cazurilor de deces la domiciliu la această categorie de populaţie

este încă mare (65,7%).

4. Cu toate că în 2010 în raionul Orhei, mortalitatea infantilă este mai redusă decât cea la nivel naţional (10,8‰ şi respectiv 12,4‰) este totuşi mai mare decât cea din 2009. Mortalitatea infantilă are aceeaşi structură (după cauza de deces) ca şi la nivel naţional. Este necesar de menţionat că 20% dintre copiii mai mici de un an au decedat la domiciliu, iar 28,5% au decedat în primele 24 ore după spitalizare. Aceste valori relevă faptul că se impun mai multe eforturi pentru prevenirea mortalităţii infantile.

5. Incidenţa şi prevalenţa la adulţi au scăzut în 2010 comparativ cu 2009. Menţionăm că aceste date nu arată situaţia reală despre morbiditatea generală a populaţiei din raionul Orhei deoarece se bazează numai pe datele de adresare. Cauzele principale ale morbidităţii populaţiei sunt: maladiile aparatului circulator, maladiile digestive. Este important de menţionat că pe parcursul ultimilor cinci ani incidenţa şi prevalenţa prin alcoolism şi narcomanie au crescut în raionul Orhei. Incidenţa tuberculozei în ultimii ani a crescut de la 92,5 la 100.000 populaţie la 121,3 în 2010.

6. Incidenţa la copii a crescut, ceea ce poate fi datorită faptului că atenţia acordată copiilor a crescut. Maladiile aparatului respirator şi maladiile infecţioase încă sunt principalele cauze de îmbolnăvire la copii, dar traumele, otrăvirile şi anumite alte consecinţe externe rămân pe primul loc în incidenţa (cazuri noi de îmbolnăvire) la copii, cu toate că acestea sunt cauze care pot fi prevenite în morbiditatea şi mortalitate la copii. Rezultatele examinării profilactice a copiilor au arătat că în raionul Orhei ponderea copiilor cu probleme de sănătate (probleme auditive, de vedere, scolioză, retard în dezvoltarea fizică) este mai mare decât la nivel naţional.

7. Pe primele locuri în structura invalidităţii primare se situează nosologiile care sunt primele în structura pe cauze de îmbolnăvire şi deces. Fiecare al patrulea caz este datorat maladiilor sistemului circulator, prima cauză fiind reprezentată de maladia hipertensivă. Pe primele locuri în structura invalidităţii sunt şi maladiile digestive, maladiile sistemului nervos şi tumorile.

8. În baza rezultatelor prezentate putem concluziona că există relaţii importante de management epidemiologic şi clinic între principalele cauze ale morbidităţii şi mortalităţii. Pentru multe din maladiile cronice (ca hipertensiunea în maladia cardiologică şi cerebro-vasculară, maladiile respiratorii, digestive) complicaţiile sunt legate de morbiditatea principală. Sublinem că majoritatea acestor maladii pot fi depistate şi aproape în totalitate administrate de un practician generalist. Cu atât mai mult că, incidenţa poate fi mult redusă prin educaţie pentru sănătate şi profilaxie primară adecvate.

9. În Asistenţa Medicală Primară cea mai importantă problemă este lipsa medicilor de familie. La acest moment în raionul Orhei sunt vacante 27 de posturi de medic de familie. Condiţiile instituţiilor de sănătate, în special în zona rurală, şi echipamentul insuficient rămân prioritare. Numărul de vizite la domiciliu efectuate de medicii de familie a crescut de la 272 895 în 2009 la 333 625 în 2010, iar valoarea medie per capita a crescut de la 2,09 în 2009 la 2,57 în 2010. Cel mai mare număr revine copiilor sub 18 ani (2,83 în 2009 respectiv 3,91 în 2010).

10. Sectorul de Asistenţă Medicală Primară a îndeplinit indicatorii de calitate în baza criteriilor CNAM: imunizare (97,6%), monitorizarea TA (97,2%), evidenţa gravidelor (78,8%) şi examenul citologic (68,7%). În acelaşi timp, ponderea anemiei la gravide este încă mare–56%, deşi Programul Unic stipulează că gravidele luate în evidenţă beneficiază gratuit de preparate de fier şi6ţ. Ponderea avorturilor este mai mare decât la nivel naţional, iar educaţia pentru sănătate, inclusiv cu gravidele, şi planificarea familiei

trebuie să fie îndeplinite pentru a reduce problemele menţionate.

11. Analiza Asistenţei Medicale Specializate de Ambulator a arătat o creştere a numărului de vizite la specialişti. În acelaşi timp, numărul vizitelor specialiştilor în teritoriu (în mediul rural) a scăzut în comparaţie cu anul 2009: 89 în 2009 respectiv 64 în 2010. Numărul pacienţilor consultaţi în timpul acestor vizite a scăzut: 9 816 în 2009 şi respectiv 2 252 în 2010. Organizarea vizitelor a fost deficitară din cauza cooperării insuficiente cu Asistenţa Medicală Primară. Cooperarea cu Asistenţa Medicală Urgentă, Asistenţa Medicală Primară, Secţiile Spitaliceşti şi Secţia Consultativă trebuie să fie îmbunătăţite.

12. În baza analizei financiare, putem concluziona că sectorul spitalicesc necesită cea mai mare rată de mijloace financiare pentru mentenanţa mijloacelor fixe, procurarea echipamentului şi a mijloacelor de transport sanitar, ceea ce reprezintă 73,3% din total. Sectorul primar necesită 20,8% şi Sectorul Specializat de Ambulator–5,85%. Costul unei vizite în Sectorul primar pentru persoanele asigurate este stabilit în sumă de 32,20 lei. În structura costului unei vizite, reparaţia mijloacelor fixe constituie 1,60 lei sau 5,1% din volumul estimat de mijloace financiare, şi pentru procurarea echipamentului (mijloace fixe) respectiv–2,80 lei (8,7%). În Sectorul Specializat de Ambulator ponderea acestor cheltuieli în structura costului este de 0,90 lei (11,7%) şi respectiv 0,60 lei (8,4%0. Costul unei zile/pat în sectorul spitalicesc este estimat la 197,90 lei. Creşterea costului unei zile/pat este de 51,9%. În structura costului unei zile/pat, procurarea de mijloace fixe este de 9,0 lei (4,5%) din mijloacele financiare estimate şi pentru reparaţia mijloacelor fixe 24,6 lei (12,4%).

SMOCHING, ALCOHOL CONSUMPTION AND PREGNANCY IN A POPULATION OF SOUTH-WESTERN ROMANAI (Abstract): The purpose of the study was to evaluate the amplitude of tobacco and alcohol consumption among two populations living in urban, respectively rural areas in the South-Western part of the country. The presence of the two risky behaviours during the pregnancy was also analysed. **Material and method**: A number of 1,200 people, men and women, aged 18-75 years, with different educational levels, living in urban and rural communities were asked to answer a questionnaire with 111 items regarding their knowledge and attitudes about the sexual-reproductive health; 11 items referred to tobacco smoking and alcohol drinking. **Results**: About half of the subjects have never smoked. The mean age of starting smoking was 16.97 years. A number of 295 subjects (24.6%) were daily active smokers, men more frequently than women ($p < 0.001$). A percentage of 77.3% of the subjects used to drink alcohol, 16.4% of them daily. The daily alcohol consumption was more frequent among men, low educated people and rural inhabitants comparing to women, respectively high educated or urban inhabitants ($p < 0.001$); 11.2% of the respondents got frequently drunk. During the last pregnancy in the couple, women and high educated people stopped smoking and drinking more frequently then men, respectively low educated people. **Conclusions**: The above findings indicate the need to start in school effective health promotion campaigns to reduce tobacco and alcohol consumption and the need for support of population-based educational interventions aimed at smoking cessation in both parents. **Key words**: SMOKING, ALCOHOL DRINKING, PREGNANCY

Este unanim acceptată ideea că sănătatea este o condiţie indispensabilă pentru desfăşurarea la parametri optimi a întregii activităţi umane, pentru atingerea unor nivele superioare de competenţă şi performanţă în plan personal, familial, socio-economic şi profesional. Obţinerea şi menţinerea unei stări optime de sănătate sunt incontestabil dictate de atitudinea pe care fiecare persoană o are faţă de factorii de risc şi de protecţie prezenţi în mediu (1).

Principalii factori ce influenţează starea de sănătate sunt acele comportamente ce intră în alcătuirea stilului de viaţă: consumul de

alcool şi de tutun, alimentaţia, activitatea fizică, regimul de odihnă. Organizaţia Mondială a Sănătăţii (OMS) apreciază că jumătate din decesele înregistrate în lume se datorează unui stil de viaţă nesănătos în care fumatul, consumul excesiv de alcool, alimentaţia neraţională şi sedentarismul joacă un rol esenţial (2). Astfel, se consideră că aproximativ 50% dintre fumătorii adulţi (estimaţi la circa 1,3 miliarde în anul 2003) vor deceda ca urmare a unor afecţiuni cauzate de fumat - accidente vasculare coronariene şi cerebrale, boli pulmonare (inclusiv cancer bronho-pulmonar) şi alte afecţiuni maligne ; peste jumătate dintre aceste decese vor surveni la vârste medii (între 45 şi 54 de ani) (3). Problemele sanitare şi sociale generate de consumul abuziv de alcool sunt tot mai acute în numeroase ţări, ca urmare fie a creşterii cantităţilor de alcool consumate, fie a modificării grupelor populaţionale de consumatori (cu referire directă la femei şi tineri) (4). Alimentaţia nesănătoasă şi inactivitatea fizică sunt printre cauzele majore ale unor afecţiuni cronice precum bolile cardio-vasculare, diabetul zaharat de tip 2 şi unele forme de cancer, contribuind esenţial la creşterea numărului global de cazuri de îmbolnăviri şi decese (5). Prin urmare, promovarea stilului sănătos de viaţă apare ca cea mai eficientă metodă de prevenire a îmbolnăvirilor şi de menţinere a stării optimale de sănătate (1, 2).

În acest context, prezenta cercetare şi-a propus evaluarea extinderii a două componente ale stilului de viaţă (consumul de tutun şi de alcool) în rândul a două populaţii provenite din medii de rezidenţă diferite. Am investigat atât un grup populaţional din mediul urban, cât şi un altul din mediul rural – segment populaţional de cele mai multe ori „uitat" de către investigatori. Am urmărit cele două comportamente atât în evoluţia lor cotidiană, cât şi în perioada ultimei sarcini survenite în cuplurile în care cel puţin un partener a fost respondent în studiul nostru.

MATERIAL ŞI METODĂ

Studiul de faţă face parte dintr-o cercetare mai amplă vizând sănătatea sexual-reproductivă a populaţiei din zona de sud-vest a României (judeţul Dolj). În cercetare au fost incluşi 1.200 de subiecţi, bărbaţi şi femei, 600 (50%) domiciliaţi în municipiul Craiova şi 600 (50%) – în comune din judeţul Dolj. Selecţia participanţilor a fost aleatorie, urmărindu-se însă crearea unei structuri cât mai echilibrate a lotului din punct de vedere al nivelului de instruire (elementar, liceal şi superior) şi al grupelor de vârstă (18-25, 26-35, 36-45, 46-55, 56-65, 66-75 ani).

Subiecţii au fost rugaţi să răspundă unui chestionar conţinând 111 itemi (pentru ambele sexe), plus alţi opt itemi specifici pentru persoanele de sex feminin ; chestionarul a cuprins preponderent itemi precodificaţi, dar şi itemi cu răspuns liber. Subiecţii au fost informaţi asupra obiectivelor şi modalităţii de aplicare a chestionarelor. Participarea lor la cercetare s-a făcut în urma consimţământului lor liber exprimat, cu respectarea permanentă a principiilor anonimatului şi confidenţialităţii. În prezentul studiu sunt analizate răspunsurile oferite de subiecţi la 11 întrebări referitoare la consumul de tutun (vârsta şi motivele de debut al fumatului, frecvenţa şi numărul de ţigări fumate) şi alcool (frecvenţa consumului – incluzând episoadele de stare de ebrietate -, tipul şi cantitatea de băuturi alcoolice consumate, situaţia consumului de alcool în familie) ; subiecţii au fost, de asemenea, întrebaţi dacă au consumat tutun şi/sau alcool în timpul ultimei sarcini (subiecţii de sex feminin), respectiv în timpul ultimei sarcini a partenerei (subiecţii de sex masculin).

Rezultatele studiului au fost prelucrate statistic folosind programul SPSS. Evaluarea semnificaţiei statistice a diferenţelor dintre subloturi s-a realizat prin intermediul testului Pearson (testul χ^2) (6,7,8).

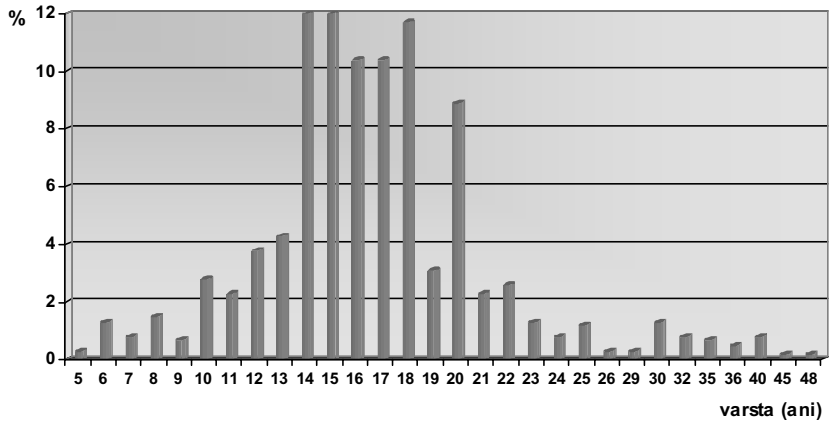

Fig. 1. Distribuţia statistică a fumătorilor (%) în funcţie de vârsta de debut a fumatului

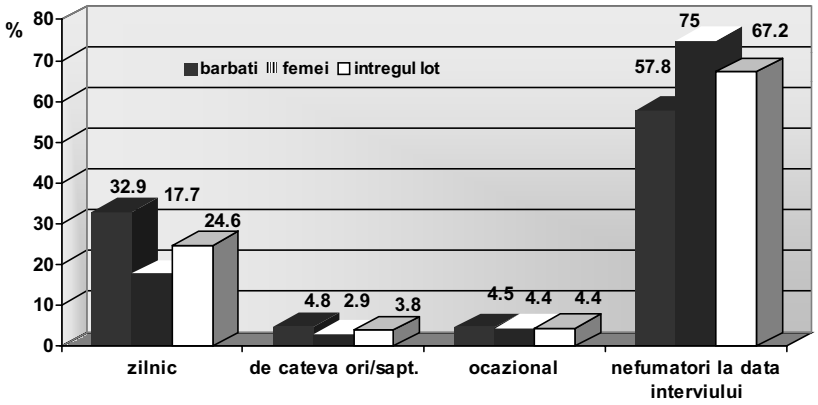

Fig. 2. Distribuţia statistică a subiecţilor (%) în funcţie de frecvenţa fumatului la data interviului

REZULTATE

FUMATUL. Prelucrarea statică a răspunsurilor oferite la întrebările din chestionar a indicat faptul că 594 de subiecţi (49,5%) nu au fumat niciodată. În cadrul lotului de 606 subiecţi (50,5%) care fumaseră cândva de-a lungul vieţii şi fumau sau nu la momentul interviului, vârsta medie de debut a fumatului a fost de 16,97 $\pm$ 5,68 ani; mai mult de jumătate dintre ei (52,3 %, N=317) erau deja fumători la împlinirea vârstei de 17 ani (fig. 1).

Cei mai mulţi dintre foştii şi actualii fumători au indicat influenţa anturajului (44,4%, N=269), curiozitatea (42%, N=255) şi necazurile (2,1%, N=13) ca fiind principalele motivele care i-au determinat să înceapă să fumeze,

La data interviului, mai mult de două treimi din subiecţi (67,2%, N=806) erau nefumători, iar ceilalţi 394 (32,8%) - fumători (fig. 2); 24,6% subiecţi din întregul eşantion (N=295, reprezentând 74,9% din numărul fumătorilor) fumau zilnic. Prevalenţa fumatului a fost mai mare în rândul bărbaţilor decât în rândul femeilor ($p<0.001$).

Cei mai mulţi dintre fumători (61%, N=240) fumau între 10 şi 20 de ţigări pe zi; un procent de 9,1% din numărul fumătorilor (N=36) consumau mai mult de 20 de ţigări pe zi, în câteva cazuri fiind menţionat chiar consumul a 40-50 de ţigări pe zi. Ceilalţi 19 subiecţi care fumau zilnic (4,8% din numărul fumătorilor) utilizau mai puţin

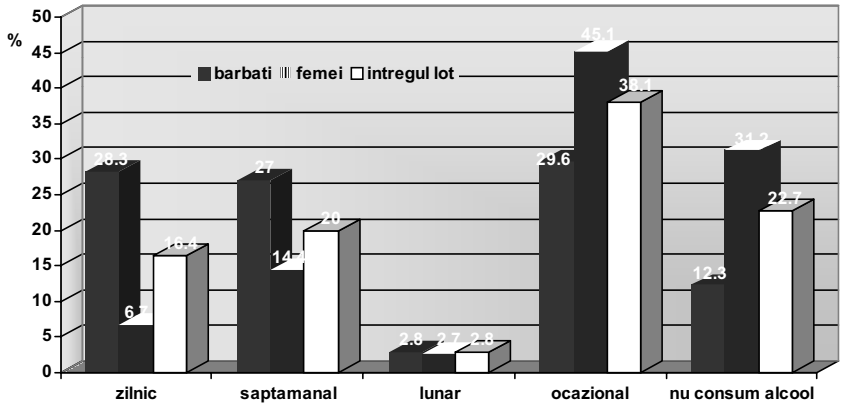

Fig. 3. Distribuţia statistică a subiecţilor (%) în funcţie de gen şi de frecvenţa consumului de alcool

de 10 ţigări pe zi.

În lotul nostru, nivelul de instruire al subiecţilor nu a determinat diferenţe statistic semnificative în ceea ce priveşte prevalenţa fumatului.

CONSUMUL DE ALCOOL. La nivel individual, rezultatele cercetării indică faptul că 197 de subiecţi (16,4%) consumau zilnic alcool la data interviului (fig. 3). Cei mai mulţi dintre subiecţi (N=457, 38,1%) s-au declarat doar consumatori ocazionali, în timp ce alţi 272 (22,7%) nu consumau deloc băuturi alcoolice. Consumul de alcool este mult mai frecvent în rândul bărbaţilor decât în rândul femeilor ($p<0.001$), aceeaşi situaţie constatându-se şi în ceea ce priveşte frecvenţa episoadelor de beţie acută (bărbaţii au fost „frecvent" în stare de ebrietate în proporţie de 23,2%, în timp ce femeile - numai în proporţie de 1,4%).

În această cercetare, atât nivelul de instruire, cât şi mediul de rezidenţă au apărut ca factori de discriminare între subloturi în privinţa consumului de alcool (tab. I), diferenţele fiind statistic semnificative pentru ambele variabile ($p<0,001$).

Astfel, s-a constatat faptul că procentul consumatorilor zilnici de alcool reprezenta 23,8% din subiecţii cu studii elementare şi doar 5,6% din respondenţii cu studii universitare, cei din urmă declarându-se, în proporţie de 49,8%, doar consumatori ocazionali de alcool.

În mediul rural, 23,1% din respondenţi au indicat consumul zilnic de alcool, în timp ce populaţia din mediul urban s-a declarat consumatoare de băuturi alcoolice ocazional (47,8%) sau la sfârşit de săptămână (16,7%).

La nivel familial, prevalenţa consumu-

TABELUL I

Distribuţia statistică a subiecţilor (%) în funcţie de nivelul de instruire şi mediul de rezidenţă, respectiv frecvenţa consumului de alcool

	FRECVENŢA CONSUMULUI DE ALCOOL				
	zilnic (% din lot)	**săptămânal (% din lot)**	**lunar (% din lot)**	**ocazional (% din lot)**	**nu consum alcool (% din lot)**
NIVEL DE INSTRUIRE					
elementar	23,8	20,6	1,7	30,2	23,7
liceal	13,2	17,9	2,9	41,4	24,6
superior	5,6	22,9	4,8	49,8	16,9
MEDIU DE REZIDENŢĂ					
urban	9,7	16,7	3,3	47,8	22,5
rural	23,1	23,4	2,2	28,4	22,9

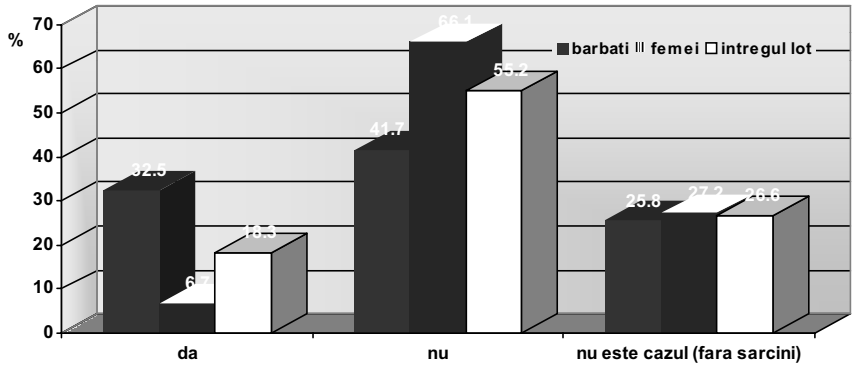

Fig. 4. Distribuţia statistică a subiecţilor (%) în funcţie de gen şi de consumul de tutun în timpul sarcinii/în timpul sarcinii partenerei

lui de alcool a indicat valori mai mari decât cele constatate în cazul consumului individual. Astfel, băuturile alcoolice se consumau zilnic în familiile a 288 de subiecţi intervievaţi (24%); numai 184 de subiecţi (15,3%) proveneau din familii în care nu se consuma alcool. Am constatat diferenţe statistic semnificative ($p < 0,001$) în funcţie de nivelul de instruire al respondenţilor, consumul zilnic de alcool fiind întâlnit în 33,6% din familiile ai căror membri prezentau un nivel elementar de instruire şi în 9,1% din cele alcătuite din persoane cu pregătire universitară.

CONSUMUL DE TUTUN ŞI ALCOOL ASOCIAT SARCINII. Rezultatele prezentate în figura 4 indică procentul redus de subiecţi (18,3%) care au continuat să fumeze atunci când în cuplu a apărut o sarcină. Remarcăm, totodată, proporţia semnificativ mai mică ($p < 0,001$) de femei care au continuat să fumeze în perioada ultimei sarcini (6,7%), comparativ cu proporţia bărbaţilor ce nu au renunţat la acest comportament (32,5%) pe parcursul sarcinii partenerei.

Prelucrarea statistica a datelor a indicat faptul că numai 7,3% din numărul total de femei au consumat băuturi alcoolice în timpul ultimei sarcini.

În tabelul II este redată distribuţia statistică a subiecţilor în funcţie de nivelul de instruire şi de consumul de tutun şi alcool în timpul sarcinii/în timpul sarcinii partenerei. Am constatat faptul că procentele persoanelor cu studii superioare care au menţinut cele două comportamente de risc în timpul sarcinii (17,3% pentru fumat, 23,8% pentru alcool) au fost mai reduse compa-

TABELUL II

Distribuţia statistică a subiecţilor (%) în funcţie de nivelul de instruire şi de consumul de tutun şi alcool în timpul sarcinii/în timpul sarcinii partenerei

NIVEL DE INSTRUIRE			
	elementar	**elementar**	**elementar**

rativ cu persoanele cu instruire elementară (20,1%, respectiv 26,6%), diferenţele fiind semnificative statistic (p=0,02, respectiv p=0,002).

DISCUŢII

În lotul analizat, procentul persoanelor fumătoare la momentul interviului a fost similar celui întâlnit în studiul naţional referitor la consumul de tutun, derulat de Centrul pentru Politici şi Servicii de Sănătate în anul 2007 (32,8% vs. 30%). Am constatat însă că subiecţii din cercetarea de faţă au început să fumeze la o vârstă mai mică (16,97 ani vs. 19,55 ani), astfel încât, în acest lot, mediana a fost 16 ani, iar în studiul naţional - 19 ani. Această constatare ar putea sugera unele deficienţe în educaţia sanitară a copiilor şi tinerilor privind efectele nocive ale (debutului precoce al) fumatului asupra sănătăţii în judeţul nostru. În ambele studii, cea mai mare parte a fumătorilor (procente situate în jurul valorii de 61%) consumau 10-20 ţigări pe zi şi aproximativ fiecare al zecelea fumător consuma mai mult de 20 de ţigări pe zi (9).

Procentul consumatorilor de alcool în lotul studiat (77,3%) a înregistrat valori crescute, în condiţiile în care cercetările arată că 64% dintre persoanele cu vârsta de peste 12 ani consumă alcool (1) Prevalenţa crescută a consumului de alcool în rândul populaţiei se datorează faptului că, pentru majoritatea oamenilor, acest comportament reprezintă o modalitate de petrecere a timpului liber, de creare a unei stări de bine, de sărbătorire a unor evenimente. Pe lângă această explicaţie, procentul mare de consumatori zilnici de alcool întâlnit (în prezentul studiu) în mediul rural a avut la bază consumul de băuturi alcoolice obţinute în gospodăria proprie; în cazul bărbaţilor, acest consum a fost estimat la 2-3 l de vin şi 300-400 ml băuturi spirtoase (ţuică) pe zi. În schimb, locuitorii din mediul urban au declarat cu precădere consumul de vin sau bere, fie ocazional, fie săptămânal, în zilele libere, cu prilejul servirii mesei alături de ceilalţi membri ai familiei – situaţie mai puţin probabilă în zilele lucrătoare.

Efectele nocive ale consumului de alcool şi tutun în timpul sarcinii sunt numeroase şi bine argumentate în literatură. Astfel, expunerea intrauterină a fătului la fum de ţigară poate genera numeroase efecte adverse asupra evoluţiei sarcinii, naşterii şi lehuziei, supune fătul la acţiunea unui puternic stres oxidativ, favorizează apariţia bolilor alergice (mai ales respiratorii) şi poate influenţa negativ creşterea în greutate a fătului, dezvoltarea sistemului său nervos şi a aparatului cardio-vascular (3,10,11,12,13). Aceste efecte pot apare atât atunci când mama este fumătoare activă, cât şi pasivă. În lotul analizat, rezultatele sugerează expunerea cu precădere pasivă a femeilor însărcinate la fumul de ţigară: procentul femeilor fumătoare active a scăzut de la 17,7% la 6,7% după apariţia sarcinii, în timp ce partenerii lor au continuat să fumeze (32,5% vs. 32,9%). Studiile arată ca majoritatea fumătorilor obişnuiesc să fumeze acasă, situaţie în care domiciliul fumătorului (alături de locul de muncă) reprezintă locul unde expunerea la fumul de ţigară a altor persoane se face în proporţiile cele mai mari. Cei mai mulţi fumători fumează în spaţiile închise de la domiciliu şi chiar în prezenţa membrilor nefumători ai familiei (9).

Expunerea prenatală la alcool poate afecta dezvoltarea fătului, generând *spectrul tulburărilor alcoolice fetale*. Cea mai severă formă de manifestare a acestuia este *sindromul alcoolic fetal,* caracterizat prin malformaţii faciale, tulburări de creştere şi afectarea sistemului nervos central (13,14,15, 16,17). În lotul analizat, numai 44 de femei (7,3%) au declarat că au consumat alcool în timpul sarcinii, procentul fiind inferior celor întâlnite în studii similare: într-un studiu coreean, 16,4% dintre femei au declarat că au consumat alcool în timpul sarcinii

(17), în timp ce 19,8% dintre femeile australiene participante la o cercetare similară au fost de acord cu consumul de alcool asociat sarcinii (18).

CONCLUZII

Prevalenţa crescută a consumului de tutun şi alcool printre participanţii la prezenta cercetare, adoptarea acestor comportamente de risc încă din copilărie sau adolescenţă şi situarea frecventă a subiecţilor în postura de „fumători activi" atrag atenţia asupra necesităţii declanşării intervenţiilor educaţionale încă din primii ani de şcoală şi intensificării lor la adolescenţi şî adulţi tineri, înainte de apariţia sarcinii în cuplu. Intervenţiile bazate pe un model teoretic al comportamentului sanogen şi care iau in considerare experienţele anterioare, influenţele sociale, percepţia riscului şi identificarea cunoştinţelor şi a concepţiilor eronate pot avea mai mult succes în rândul tinerilor decât o abordare educaţională tradiţională.

MULŢUMIRI

Acest studiu a fost efectuat în cadrul proiectului „Coordonate antropologice şi psiho-medicale ale sănătăţii sexual-reproductive la populaţii din mediul urban şi rural" – Program IDEI, cod 72/2008, finanţat de CNCSIS-UEFISCSU.

GHRELIN AND ANG 1-7 HAVE VASODILATATORY CUMULATIVE EFFECTS ON PULMONARY VESSELS (Abstract): Ghrelin is an orexigenic hormone that has been shown to have vasodilator effects. Angiotensin 1-7 (Ang 1-7) is a bioactive component of the renin-angiotensin system and may play an important role in the regulation of cardiovascular homeostasis. **Aim**: The aim of this study was to investigate the interaction between ghrelin and a better known vasodilatator, Ang 1-7. **Material and method**: The dose – dependent relaxing effects of ghrelin were assesed on pulmonary artery rings of male Wistar rats with intact endothelium in the absence or the presence of Ang 1-7. Ang 1-7 was added in the organ bath with 5 minutes before N^G-nitro L-arginine methyl ester (L-NAME, 1 μM) and indomethacin administration in the presence of cumulative doses of ghrelin. **Results**: Our results showed that Ang 1-7 could improve and restore vasorelaxant effects of ghrelin on rat pulmonary rings with intact endothelium. **Conclusion**: Vasodilatatory actions of ghrelin are potentiated by Ang 1-7 and mediated by local synthesis of prostaglandins and nitric oxide. **Key words**: GHRELIN, ANGIOTENSIN 1-7, PULMONARY RAT ARTERY, NITRIC OXIDE

Ghrelin was identified in 1999 (1) as the endogenous ligand of growth hormone secretagogue receptor 1a (GHSR-1a) described by Howard et al. in 1996 (2). Ghrelin has been viewed by many researchers as a central modulator of energy homeostasis and a regulator of growth hormone secretion (3). Some studies revealed cardiovascular effects of ghrelin, including lowering of peripheral resistance, possible improvement of contractility and cardioprotective effects both *in vivo* and *in vitro* (4).

The aim of this study was to investigate the interaction between ghrelin and a better known vasodilatator, angiotensin 1-7 (Ang 1-7) (5). In addition both the cyclo-oxygenase inhibitor indomethacin and the nitric oxide synthetase inhibitor N(G)-nitro L-arginine methyl ester (L-NAME) were investigated.

MATERIAL AND METHOD

The experiments were conducted in age-matched Wistar male rats (Bucharest Cantacuzino Institute) with body weights of 150-200 g housed under standard laboratory conditions, with free access to standard rodent chow and tap water. This study was approved by the Ethics Committee of the University of Medicine and Pharmacy "Grigore T. Popa" Iasi and it was performed according to the Helsinki convention for the use and care of animals, and to the European Communities Council Directive 609 of 24 November 1986. Rats were decapitated and exsanguinated. The rat pulmonary artery was rapidly removed,

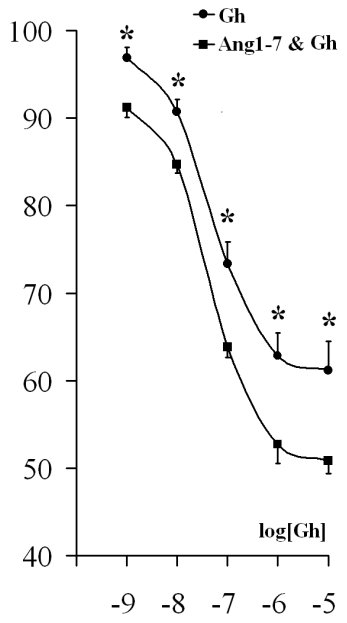

Fig. 1. Effects of ghrelin (Gh, 10 nM – 10 μM) on rat pulmonary artery ring preparations with intact endothelium precontracted with 1 μM phenilephrine in the absence and the presence of 10 μM Angiotensin (Ang1-7) (n=6). Data are presented as percentage of pre-contraction induced by 1 μM phenilephrine. *: $p<0.05$ as compared with ghrelin alone

cleaned and cut into rings, 2 mm wide. Individual rings were then mounted between wires in a MYO-01 MYOGRAPH SYSTEM (Experimetria LTD., Budapest, Hungary) and changes in vessel tension were recorded and analyzed by ISOSYS data acquisition system (Experimetria LTD., Budapest, Hungary). Changes in isometric tension were monitored using force transducers connected to a PC via the PC–LPM–16 multifunctional I/O board (National Instruments Corp., Austin TX), driven by the respective standard software (NiDaqWin). The tissue organ bath contained the Krebs–Henseleit solution containing (mM): NaCl 118, KCl 4.8, CaCl2 2.5, MgSO4 1.6, KH2PO4 1.2, NaHCO3 25, glucose 5.5. The Krebs-Henseleit buffer was maintained at 37°C, and bubbled continuously with a mixture of 95% O2 and 5% CO2 (pH=7.2–7.4). A resting tension of 0.5 g for rat pulmonary artery was applied to each ring and then allowed to equilibrate for 90 minutes before the start of the experiment. The bathing medium was renewed from 15 to 15 minutes.

Nitric oxide (NO) releasing was measured using an APOLLO 4000 system (World Precision Instruments - WPI). The method was previous described (6). Calibration of 30 microns diameter L-shaped electrodes (ISO--NOP30-L) using S-Nitroso-N-acetyl-D, L-penicillamine (SNAP) was made accordingly to WPI technical indication.

After the equilibration period, vessel rings were initially stimulated with 40 mM KCl as a standard stimulus. After re-equilibration in Krebs solution for 45 min, the 10 μM phenylephrine (Phe) was used to generate a sustained contraction; the relaxant responses to cumulative concentration of ghrelin (10 nM – 10 μM) were subsequently studied. Angiotensin 1-7 (10 μM) was added in the organ bath with 5 minutes before L-NAME (10 μM) and indomethacin (1 μM) administration in the presence of cumulative doses of ghrelin (10 nM – 10 μM).

Expression of results and statistical analysis : The results are expressed as the percentage of the control contraction (KCl, 40 mM; mean ± S.E.M.). Statistical significance was tested using one-way analysis of variance (ANOVA), completed with Bonferroni method (SigmaStat software, Jandel Corporation). $p<0.05$ was considered statistically significant.

Phenilephrine, angiotensin 1-7, L-NAME, indomethacin, recombinant rat ghrelin were all obtained from Sigma (Sigma-Aldrich Inc., St. Louis MO). All the other compounds used were of analytical grade.

RESULTS

The relaxing effects of ghrelin cumulative doses are presented in fig. 1. Admi-

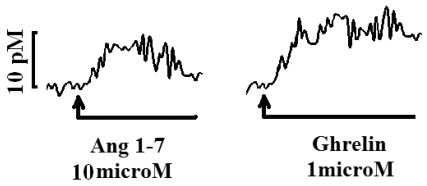

Fig. 2. Nitric oxide releasing on rat pulmonary rings by 10 μM Ang 1-7 and 1 μM ghrelin.

nistration of 10 μM Ang 1-7 had significant amplificatory effect on ghrelin – induced vasorelaxation: the Emax became 50.86$\pm$1.42 in the presence as 61.21$\pm$3.30 in the absence of of Ang 1-7 ($p<0.05$). The EC50 was not significantly different (48.61 nM without Ang 1-7 *vs*. 47.14 nM with Ang1-7).

The NO – releasing effects of 10μM Ang 1-7 and 1 μM ghrelin (Gh) on rat pulmonary arteries with intact endothelium are presented in fig. 2. The ghrelin – induced NO releasing effects were with at least 25% higher than Ang1-7.

The L-NAME pre-treatment (fig. 3) dramatically decreased the ghrelin -induced relaxation (E_{max} = 88.08$\pm$1.76). The Ang1--7 significantly increased the ghrelin effects just for 0.1 μM (83.71$\pm$2.03 *vs*. 91.22$\pm$1.73), 1 μM (80.42$\pm$2.55 *vs*. 88.08$\pm$1.38) and 10 μM (77.38$\pm$2.76 *vs*. 90.20$\pm$2.52).

Inhibition of prostaglandin synthesis (fig. 4) with 10 μM indomethacin (Indo) did not decrease the ghrelin effects with exception of low doses (100.94$\pm$0.95 *vs*. 96.88$\pm$1.22 for 10 nM ghrelin; 81.01$\pm$1.30 *vs*. 73.35$\pm$2.52 for 0.1 μM ghrelin). In this conditions the amplificatory Ang1-7 effects were still maintained, even if were lower as compared with results obtained without Indo (63.92$\pm$1.25 *vs*. 71.94$\pm$2.13 for 0.1 μM ghrelin; 52.76$\pm$2.17 *vs*. 59.82$\pm$1.17 for 1 μM ghrelin; 50.86$\pm$1.42 *vs*. 55.56$\pm$0.93 for 10 μM ghrelin).

Incubation of vascular rings (fig. 5) with both L-NAME and Indo blocked the relaxation and revealed moderate vasoconstrictory ghrelin effects (E_{max} = 117.99$\pm$3.97). Pre-treatment with Ang1-7 did not modify the ghrelin effects.

DISCUSSIONS

Ghrelin (10 nM – 10 μM) had dose dependent relaxant effects on the pulmonary rat ring preparations with intact endothelium pre-contracted with 1 μM phenilephrine (fig. 1). Ang 1-7 potentiated vasodilatatory effects of ghrelin (fig. 1). Taking into account that Ang (1-7) actions are dependent by both NO and vasodilatatory PGs we attempt to investigate the roles of these two mediators in the ghrelin effects.

Both, Ang 1-7 and ghrelin could stimulate nitric oxide (NO) releasing on rat pulmonary rings with intact endothelium (fig. 2).

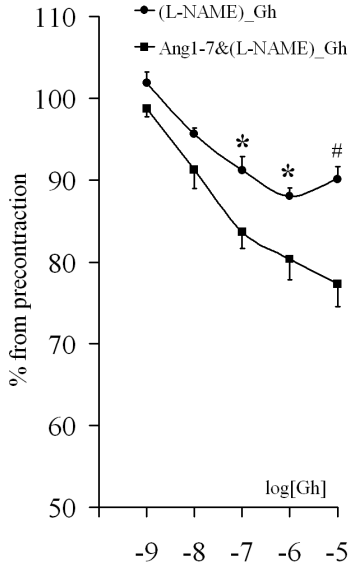

Fig. 3. Influences of 10 μM Angiotensin (Ang1-7) on ghrelin (Gh, 10 nM – 10 μM) effects on rat pulmonary artery ring preparations precontracted with 1 μM phenilephrine and incubated with 10 μM N(G)-nitro L-arginine methyl ester (L-NAME) (n=6). Data are presented as percentage of pre-contraction induced by 1 μM phenilephrine. * $p<0.05$ in absence as compared with presence of Ang1-7; # $p<0.01$ in absence as compared with presence of Ang1-7

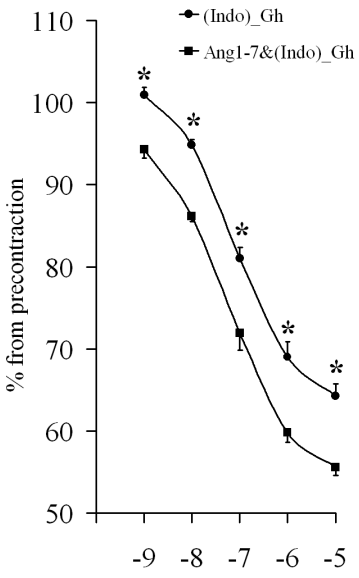

Fig. 4. Influences of 10 μM Angiotensin (Ang1-7) on ghrelin (Gh, 10 nM – 10 μM) effects on rat pulmonary artery ring preparations precontracted with 1 μM phenilephrine and incubated with 1 μM indomethacin (Indo) (n=6). Data are presented as percentage of pre-contraction induced by 1 μM phenilephrine. *: $p<0.005$ in absence as compared with presence of Ang1-7

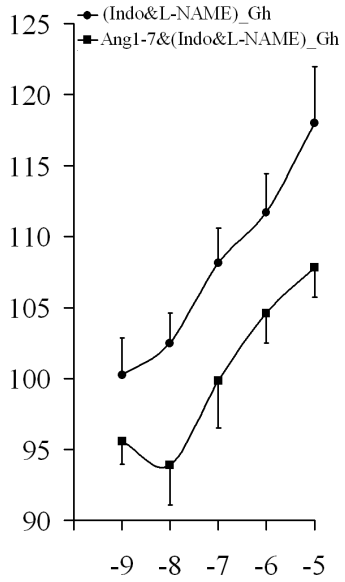

Fig. 5. Influences of 10 μM Angiotensin (Ang1-7) on ghrelin (Gh, 10 nM – 10 μM) effects on rat pulmonary artery ring preparations precontracted with 1 μM phenilephrine and incubated with 1 μM indomethacin (Indo) and 10 μM N(G)-nitro L-arginine methyl ester (L-NAME) (n=6). Data are presented as percentage of pre-contraction induced by 1 μM phenilephrine

It is generally accepted that NO is a potent vasodilator that derives from the oxidation of L-arginine by NO synthetases (NOSs): neuronal NOS (nNOS, brain NOS or type I NOS), inducible NOS (iNOS or type II NOS) and endothelial NOS (eNOS or type III). eNOS and nNOS are calcium – dependent constitutive enzymes that generate small amounts of NO involved in vasodilation / maintenance of vascular tone, antiplatelet aggregation and neurotransmission. iNOS is a calcium - independent inducible enzyme that produces great amounts of NO. Our results agree well with those from the studies on human vessels *in vivo* who showed that ghrelin could have vasodilatatory effects partially mediated by NO (7,8). The next step was to investigate the functional significance of this NO releasing effect of ghrelin. So, we assessed the vasodilatatory effects of ghrelin on pre-contracted pulmonary artery rings but in presence of L-NAME. The relaxant effects of ghrelin were markedly reduced, but not totally blocked on the presence of 1 μM L-NAME (fig. 3). Even more, the Ang1-7 presence effects was lower (two third from Ang1-7 effects in absence of L-NAME) amplificatory effect on ghrelin – induced vasorelaxation (fig. 4). So, both the ghrelin actions and the Ang1-7 effects on ghrelin--induce vasorelaxation were partially dependent by NO.

In order to verify if vasodilatatory effects of ghrelin are due to prostaglandin synthesis we repeated the experiments in the presence of 1 μM indomethacin. The relaxant effects of ghrelin were slightly reduced by indomethacin (fig. 4) and the Ang1-7

amplificatory effects were maintained. Nevertheless, the incubation of rat pulmonary rings with indomethacin reduced the vasodilatatory effects of 1 - 100μM ghrelin in the presence of Ang1-7.

Blocking of local synthesis of both nitric oxide and prostaglandins uncover the barely vasoconstrictor effects of ghrelin (fig. 5). In this case, the Ang1-7 did not modify the Gh effects. So, similar to other vascular territories (9), the vasodilatatory effects of Ang1-7 on pulmonary arteries were mediated by NO and prostaglandins.

CONCLUSIONS

Ghrelin induced dose-dependent and nitric oxide mediated vasodilatatory effects on phenylephrine pre-contracted rat pulmonary artery rings. Even more vasodilatatory actions of ghrelin are potentiated by Ang 1-7. The Ang1-7 actions are mediated by local synthesis of nitric oxide and prostaglandins with vasodilatatory effects.

RESEARCHES ON IMMUNE SYSTEM RESPONSE, SKIN AND HEPATIC REACTIVITY IN LABORATORY ANIMALS AFTER RETRO-AURICULAR TOPICAL ADMINISTRATION OF TWO REACTIVE TEXTILE DYES (Abstract): **Aim**: To evaluate immune system response, skin and hepatic reactivity in Swiss mice after retro auricular local administration of two textile dyes. **Material and methods**: On 3 groups of white Swiss mice: group I (Cibacron Yellow F-4G), group II (Cibacron Orange P-2R) and control group (DMSO - dimethylsulfoxide), substances were applied on left retro auricular ear, in dose of 25 μL solution 10% in DMSO (the dyes were not soluble in water), once a day, for 7 days. After euthanasia, blood samples were taken to assay differential cell count, peripheral neutrophils activity (NBT test), serum opsonic capacity, peritoneal macrophages activity (phagocytic and bactericidal capacity), and activity of spleenic T-lymphocytes with rossetting capacity, and spleen cells forming Jerne plaques. There were taken skin from local application of dyes, retro auricular and later cervical nodes from left side and hepatic samples. **Results**: Retro auricular and later cervical nodes mass increases after administration of textile dyes, compared to control group. Basophiles percentages were increased after administration of two dyes (stronger after yellow dye). Peripheral neutrophils activity was increased after administration of two dyes, especially after orange dye. Administration of the two dyes decreased serum opsonic capacity and peritoneal macrophages activity, but did not influenced the activity of spleenic T-lymphocytes with rossetting capacity and spleen cells forming Jerne plaques. There were significant skin and hepatic changes in microscopy. **Conclusion**: The studied dyes influenced the activity of immune system, increased skin and hepatic reactivity. **Key words**: TEXTILE DYES, IMMUNE SYSTEM RESPONSE, SKIN AND HEPATIC REACTIVITY

DEVELOPMENT AND VALIDATION OF A METHOD FOR QUANTITATIVE DETERMINATION OF AMIODARONE HYDROCHLORIDE IN BLOOD SERUM BY HPLC-MS-MS

DEVELOPMENT AND VALIDATION OF A QUANTITATIVE METHOD FOR THE EVALUATION OF AMIODARONE HYDROCHLORIDE BY HPLC-MS-MS IN BLOOD SERUM (Abstract) **Aim**: The paper presents the development and validation stages of a new method using high performance liquid chromatography coupled with mass spectrometry for the determination of amiodarone hydrochloride in blood serum. **Material and methods**: The method used a TSQ Quantum^{TM} Access MAX Triple Quadrupole Mass Spectrometer coupled with a HPLC Transcend TLX1 system and octadecylsilyl silica gel C_{18} Cyclone MAX polymeric chromatographic columns (50 mm x 2.1 mm; 1.9 μm). Mass spectrometry detection was based on transition of ions from 645.9 to 200.23 m/z, while the other parameters were: 2400 V ionization potential, 10 psi pressure of gas ionization, 60 psi auxiliary gas pressure, 2.8 mTorr energy collision, 200°C ionization temperature and 330°C capillary temperature. A thorough validation study was conducted that included identifying the characteristic peaks of amiodarone hydrochloride, evaluating system compatibility, studying linearity and accuracy, establishing chromatographic retention times, limits of detection and quantification. **Results:** The retention time for amiodarone hydrochloride was 2.42 minutes, the method was linear over the concentration range 0.05-1.25 mg/mL, the limit of detection was 5.38 mg/mL, the limit of quantification was 17.68 mg/mL, and the regression coefficient was $r^2 = 0.9986$. **Conclusions:** The HPLC-MS-MS method developed and validated for the quantitative determination of amiodarone hydrochloride in serum is fast, specific and simple, and it can be used with good results during the *in vivo* studies required for the development of new therapeutic systems of amiodarone. **Keywords:** AMIODARONE, HPLC-MS-MS, BLOOD SERUM.

Amiodarone (AMD) is one of the most frequently prescribed therapeutic agents for the treatment of cardiac tachycardia worldwide due to its unanimously recognized efficiency. The mechanism of action includes the prolongation of action potential and effective refractory period of the myocardial fibers especially in the atria and His-Purkinje system, but also in the ventricular myocardium, and a the decrease in sinus node automatism. AMD determines atrioventricular conduction delay, de-

creased heart rate and significant lengthening of the Q-T interval on standard electrocardiogram (1, 2, 3).

The physicochemical properties of AMD were at the basis of this analytical study in order to develop new quantitative methods consistent with drug control regulations for bulk substance and solid oral dosage forms with modified and immediate release (4, 5).

For the quantitative analysis of AMD conditioned into modified release solid oral pharmaceutical formulations F1 and F10 or as amiodarone/hydroxyl-propyl-β-cyclodextrine inclusion complex (HP-β-CD/AMD), we have previously developed and validated a new HPLC method for the assay of AMD for *in vitro* studies. An exhaustive study on the quantitative determination methods of AMD from raw materials, formulations and biological fluids was at the basis of the method presented in this article. Most of the reported methods either do not include stress degradation studies, are validated incompletely, or are time consuming, cumbersome and expensive. For that reason a novel method using HPLC coupled with MS was developed and validated, method that is fast, specific and easy to use for the quantitative determination of AMD in blood serum (6-8).

MATERIAL AND METHODS

The reagents used were: methanol HPLC grade (Merck, Germany), formic acid, ammonium formate (Merck, Germany), acetonitrile, isopropanol, acetone HPLC grade (Merck, Germany), HP-β-CD - 99.70% purity (Roquette France), amiodarone hydrochloride (AMD·HCl) - 99.85% purity (Zhejlang Pharmaceutical Co. Ltd., China), HP-β-CD/AMD complex - 99.80% purity (”Petru Poni” Institute of Macromolecular Chemistry Iasi, Romania), Millipore-filtered water - 0.01 μS/cm conductivity.

The solution used were: sample solution (1 mL serum sample plus 2 mL of acetonitrile were sonicated for 5 minutes and then centrifuged for 10 minutes at 4000 rpm and decanted off), 0.01 mg/mL AMD standard solution (100 mg AMD·HCl were dissolved in water and diluted to 100 mL, and then 0.1 mL were diluted with mobile phase up to 10 mL).

The chromatographic parameters used were: chromatographic column 1 - C_{18} octadecylsilyl silica gel (0.05 m x 2.1 mm, 1.9 μm, 25°C), chromatographic column 2 - polymeric Cyclone MAX (0.05 m x 2.1 mm, 1.5 μm, 50°C), mobile phase A (for C1) 0.1 mM ammonium formiate and 0.001% formic acid, mobile phase B – water, mobile phase C - methanol, mobile phase D - acetonitrile: isopropanol: acetone (40:40:20) (v/v/v) (last 3 for C2). The volume of sample injected was 5 μL.

The quantitative determination of AMD was based on the external standard method. The method was based on separation of the analyte from the biological matrix through chromatographic techniques with mass spectrometry detection.

The chromatographic method of analysis included two phases. First, the distribution of the analyte was carried out through column 1 which provided a turbulent flow, and then the analyte was transferred to column 2 for separation and identification by MS. The column was prepped with the mobile phase at a flow rate of 0.5 mL/min for 30 minutes.

Validation procedure

The chromatographic peaks were identified by injecting a solution containing the active substance AMD in the biological matrix – blood serum.

Chromatographic system compatibility study was done by injecting 10 times con-

secutively 200 ng/mL of AMD solution. Injection repeatability, reflected in the invariability of both peak area and retention times, defined the accuracy of the system. Also peak asymmetry and number of theoretical plates in the column were two other factors that characterized system compatibility.

The linearity study of the signal corresponding to AMD·HCl was done by plotting the calibration curve over the linearity range 0.05-1.25 µg/mL. Three independent series of these solutions for each concentration level have been used (9,10).

In order to study the accuracy of the analysis method, spiked samples were prepared containing various amounts of AMD·HCl dissolved in a mixture of 500 mL plasma and 500 mL water, as follows: SP1 - 1250 ng AMD, SP2 - 1000 ng AMD, SP3 - 500 ng AMD, SP4 - 200 ng AMD, SP5 - 75 ng AMD, SP6 - 50 ng AMD. The recovered concentration ($C_{recovered}$), percentage recovery (R%), and percent deviation (Xd%) were calculated, while the obliquity of the experiment was evaluated.

For the calculation of the limit of detection (LOD) and limit of quantification (LOQ), the standard deviation and the slope of the regression curve were used according to the following equations: LOD = 3.3 × SD/slope and LOQ = 10×SD/slope (11-12).

RESULTS AND DISCUSSION

The results obtained for the identification of the corresponding peaks of AMD·HCl (fig. 1-4) are reported in table I.

The experimental results obtained in the linearity study are presented in table II.

Estimation of peak areas had been done using linear regression equation: Area = 4.142 x Concentration.

The fitting of peak areas based on the variation of residual values according to the concentration of AMD·HCl is shown in table III.

The experimental results of the accuracy study are presented in table IV.

The experimental results of the linearity study are presented in table V.

TABLE IV

Study on method accuracy

Sample	Theoretical concentration (ng/mL)	$C_{recovered}$ (ng/mL)	R%
SP1	50	48	96
SP2	75	72	96
SP3	200	196	98
SP4	500	490	98
SP5	1000	970	97
SP6	1250	1191	95

TABLE V
Linearity of the method

$C_{AMD \cdot HCl}$	50	75	200	500	1000	1250
Area(S1)	62.00	185.00	793.73	1984.33	4249.00	5258.67
Area(S2)	68.54	186.00	794.73	1984.22	4334.00	5345.00
Area(S3)	53.75	184.00	792.55	1953.40	4149.00	5144.00
Average	60.30	185.00	793.50	1973.98	4244.00	5249.22

The limits of detection and quantification were calculated based on the response to the lowest concentration for which the relative standard deviation has been determined, and it was then compared to the slope. The values of the limit of detection and limit of quantification were found to be 5.83µg/mL and 17.68 µg/mL, respectively.

The method was validated in accordance with international regulations (13,14). The representative chromatograms of AMD free and spiked plasma samples showed no secondary peaks of interfering substances such as endogenous plasma components, with similar retention time. The retention time of the analyte was 2.42 minutes.

All accuracy and precision values were within the recommended range. The degree of recovery ranged from 95% to 98% (15,16).

Injection repeatability, peak area and retention times defined system accuracy. Also peak symmetry and number of theoretical plates of the column were two other factors that characterized the compatibility of the system. Injection repeatability was proven by RSD $\leq$ 2.

Under the experimental conditions, it was observed that the confidence interval for the average area (793.67) was X = -362.87 ÷ 1950.20 and $RSD\%_{AMD}$ (area) was 1.59. Stretch factor was T $\leq$ 1.8, and T_{AMD} = 1.1.

The number of theoretical plates for AMD·HCl was N_{AMD} = 3757. Calibration curve showed a linear variation of the peak area with sample concentration. During accuracy study, the experimental data highlighted an 80.48% average recovery (17,18).

CONCLUSIONS

We validated the new method in a 0.05-1.25 µg/mL concentration range, covering the therapeutic plasma concentration of amiodarone hydrochloride.

The developed method developed is simple, fast, and accurate and it did not involve great cost. Compared to other published HPLC methods for the assay of amiodarone hydrochloride in animal plasma, the new method performed better in terms of speed and cost, important characteristics for the methods used routinely.

We have successfully used the newly validated method in a pharmacokinetic study, but it may also have widespread applications in monitoring AMD therapeutic concentration in blood serum during studies investigating drug interactions and in toxicological research.

AUTOMATIC ANALYSIS OF CARDIOTOCOGRAPHIC RECORDINGS FOR FETAL ACIDOSIS STUDY (Abstract) **Aim**: Fetal acidosis is a consequence of anaerobic metabolism due to lack of or a limited amount of oxygen delivered through the umbilical cord to the fetus. Direct determination of fetal blood pH remains the current method used in practice and needs fetal blood extraction. This is an elaborate procedure and cannot be performed or repeated anytime during labor. An alternative, non-invasive solution is to monitor continuously the fetus through cardiotocography (CTG). **Material and methods:** This paper presents an automatic analysis software tool designed and implemented in Matlab, which computes a fetal heart rate (FHR) baseline, identifies accelerations, decelerations of FHR signal and characterizes maternal uterine contractions. **Results and discussion**: The software was tested using a public cardiotocography database available from Physionet.org. We looked for results consistency in term of events per hour and if the software may differentiate between normal and metabolic acidosis (pH<7.2) group. We found in acidosis group, a significant increase in number of traces with prolonged decelerations. Also, there is a significant difference in the mean number of accelerations and late deceleration per hour of CTG trace. The mean number of uterine contractions, expressed per hour of CTG trace was, not significantly different. **Conclusions:** We developed and implemented a Matlab software used for CTG analysis, respectively identification of accelerations, decelerations and uterine contractions. The software was tested using a public database of intrapartum CTG recordings. CTG parameters analyzed by an in house developed software could reliable identify the characteristics related to fetal metabolic acidosis. **Keywords:** CARDIOTOCOGRAPHIC RECORDINGS, FETAL ACIDOSIS.

Fetal metabolic acidosis represents one of the factors that cause fetal distress. Unrecognized and untreated can lead to issues after birth such as neurological damage, intracranial hemorrhage, cerebral palsy and in worst case scenarios still birth (1). Metabolic acidosis is caused by anaerobic metabolism due to low concentrations of oxygen in the blood of the fetus. This is caused by different factors limiting the amount of oxygenated blood that is supplied to the fetus (2). If this type of metabolism is present for a longer period, the fetal buffers will be exhausted and the blood will

change its pH value from the normal level higher than 7.2 to an acidic level. This phenomenon occurs due to the production of organic acids such as lactic acid as a byproduct of anaerobic metabolism. In time, the concentration of organic acids will be higher due to the low natural rate of absorption (3).

The fetus has a series of defense mechanisms that activate when metabolic acidosis sets in, the most predominant being an increase of heart rate or accelerations. If these mechanisms do not lead to the normalization of pH values, in time the heart rate will change into late and prolonged decelerations that are considered pathological (4).

The purpose of this paper is to present the implementation of a software tool that can be used to analyze cardiotocographic (CTG) recordings to highlight the main effects of fetal metabolic acidosis. We analyzed fetal heart rate (FHR) and maternal uterine contractions (UC) to determine accelerations per hour, decelerations per hour and contractions per hour.

MATERIAL AND METHODS

1. Software tool

Available intrapartum CTG recordings contained the signals of fetal and maternal heart rate, uterine contractions / pressure and maternal blood pressure (5). We focused on the analysis of FHR and UC signals from these CTG recordings, as they are interrelated and offer the most information about the fetus wellbeing.

The software was developed in Matlab and the CTG traces were analyzed by two sub functions for FHR and UC, respectively. At the beginning of analysis, we used some preprocessing procedures, to improve signal quality.

The first preprocessing procedure used a smoothing filter of a moving window of 30 samples, centered on the current analyzed sample. This removes abrupt spike values in the signal, caused by maternal movement artifacts (6).

$$X_s(i) = \frac{1}{2N+1} \sum_{j=-N}^{N} x(i+j) \quad (1)$$

where $X_s(i)$ is, the value obtained after applying the smoothing filter, i is the index of the sample that is analyzed and N is the length of the filtering window, in this case 30 samples (7).

Second preprocessing procedure consisted in a curve fitting spline interpolation algorithm for the FHR signal to remove signal segments where the sample value is equal to zero. These segments correspond to artifacts caused by a loss of electrode contact to the fetus' scalp (8). Figure 1 presents an example of CTG signals after we applied the preprocessing procedures.

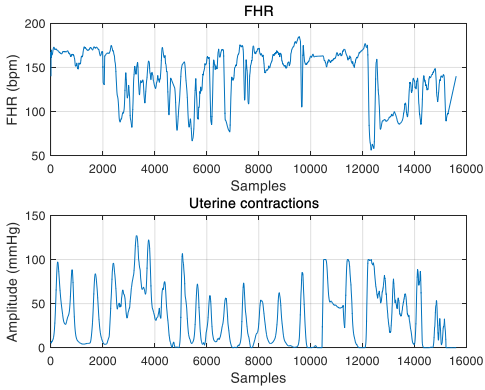

Fig. 1. Pre-processed FHR and UC signals. FHR, fetal heart rate; bpm, beats per minute.

Determination of FHR baseline allows characterization of accelerations and decelerations. We determined the baseline value (in beats per minute, bpm) by identifying segments of the signal where the sample

values, compared to an average baseline value, differ by less than 10 bpm (9). For this, we computed the first derivative of FHR signal (dFHR), which allows identification of the very high and very low amplitude samples that are not part of the baseline, as presented in figure 2. These values, identified as very high or low amplitude using the first derivative, were not used to compute the average baseline value. Samples used for baseline assessment must be part of segments with a length greater than 15 seconds (60 samples), with an amplitude between ±10 bpm, compared to the average baseline (10). We determined the segments that corresponded to FHR baseline and we computed the average value baseline from these segments, as presented in formula (2):

$$FHR_{Avg_baseline} = \frac{\sum_{n=i}^{i+N} FHR_{Bs}(n)}{N} \quad (2)$$

where $FHR_{Avg_baseline}$ is the average baseline value determined for all the identified baseline segments, i is the index of the starting sample of the segment in the FHR signal, N is the number of samples of that segment and $FHR_{Bs}(n)$ is the amplitude of the sample n that is part of a baseline segment.

After the average baseline value and the baseline segments determination, we combined segments into a baseline continuous signal using linear interpolation. In order to combine two consecutive segments, we used the last sample of the current baseline segment and the first sample of the next baseline segment (11). For the first segment identified we used the FHR signal origin, and for the last identified segment we used the FHR signal end sample. Thus, we defined the two samples $FHR_{seg(k)}(i+N)$ and $FHR_{seg(k+1)}(i)$, where k represents the total number of segments identified, to compute a linear interpolation between them, as presented in formula (3).

$$FHR_{Linear_interp}(j) = FHR_{seg(k)}(i+N) + (j-(i+N)) \times \frac{FHR_{seg(k+1)}(i) - FHR_{seg(k)}(i+N)}{i-(i+N)} \quad (3)$$

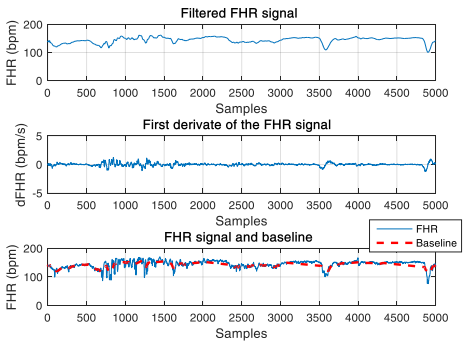

Fig. 2. Determined FHR baseline compared to the FHR signal.
FHR, fetal heart rate; bpm, beats per minute; dFHR, fetal heart rate first derivate.

Accelerations are considered normal events during pregnancy. For their detection, we defined a set of quantitative parameters that describe this type of event: the length of the acceleration has to be over 60 samples (15 seconds) and the amplitude has to be 15 bpm higher than the baseline in that signal segment (fig. 3) (12).

Other episodic events related to FHR and uterine activities are decelerations. They are divided into three types.

First type is represented by early decelerations. They are considered normal events that occur at the same time as a uterine contraction and don't differ by

more than 40 bpm compared to the baseline (13). The early deceleration returns normally to baseline value by the end of contraction.

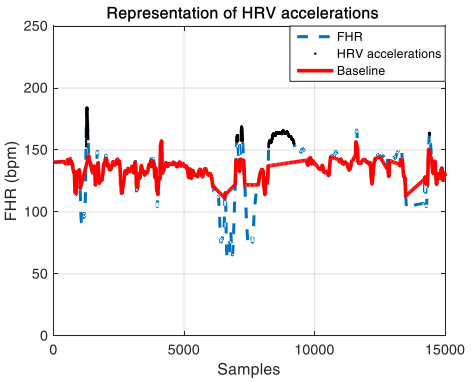

Fig. 3. Representation of heart rate accelerations. FHR, fetal heart rate.

The second type is the late decelerations which are considered pathological events (fig. 4). These appear after the initiation of contraction, and their minimum value occur at least 15 seconds after the contraction peak. To identify this type of decelerations, significantly associated with fetal acidosis, we imposed a set of quantitative parameters: the amplitude of the signal should be more than 40 bpm lower than the baseline value for that signal segment and the deceleration should last over 120 samples (30 seconds) (14).

The third type is represented by prolonged decelerations, long segments with a length between 2 and 10 minutes, with an amplitude 40 bpm lower than the baseline value in that signal segment. A prolonged deceleration over 10 minutes represents a changing in baseline. These decelerations decrease the oxygen transferred to the fetus and represents a high risk for fetal acidosis (fig. 5) (15).

To characterize and compare CTG tracings, we calculated the number of accelerations or decelerations per hour. The formulas used to determine these values are:

$$Acc/h = \frac{N_{Acc}}{L/F_s/3600} \quad (4)$$

where *Acc/h* is the accelerations per hour, N_{Acc} is the total number of identified HRV accelerations, L is the total signal length and F_s is the sampling frequency.

$$Ldcc/h = \frac{N_{Ldcc}}{L/F_s/3600} \quad (5)$$

where *Ldcc/h* is the value of late decelerations per hour, N_{Ldcc} is the total number of identified late decelerations, L and F_s have the same signification as formula (4).

We designed and implemented an algorithm that analyses uterine contractions, in terms of contractions/hour. To identify uterine contraction (UC) we implemented a peak finder algorithm, which computes the first derivative of the UC signal and thus identifies high amplitude samples. We identified the sample with the maximum amplitude. This is used to determine the threshold value to which all samples are compared.

The threshold value is set at 40% of the maximum value sample (16). We then compare the samples to the threshold value to obtain only high amplitude samples. This step allows us to identify signal segments of high amplitude. The maximum value sample of each of these segments is considered the peak of the contraction.

In case the contraction has two or more peaks we use a selection threshold of 20% difference in amplitude between two consecutive peak samples to identify false peak detections and keep only the value that corresponds to the real contraction peak (17).

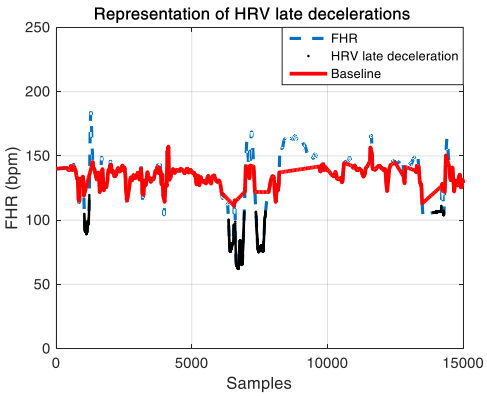

Fig. 4. Representation of late decelerations. FHR, fetal heart rate.

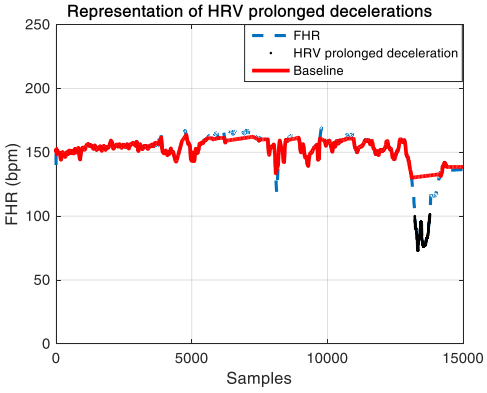

Fig. 5. Representation of prolonged decelerations. FHR, fetal heart rate.

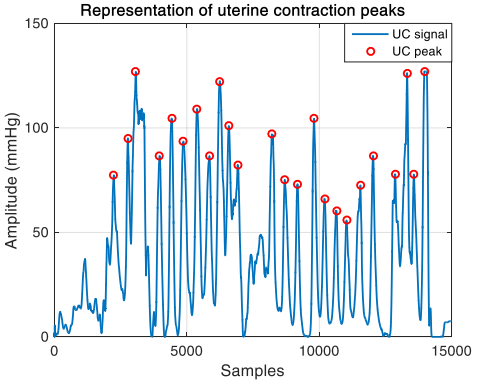

Fig. 6. Representation of the identified contraction peaks

We computed the contractions per hour parameter as a risk factor for fetal stress.

$$NC/h = \frac{NC}{L/F_s/3600} \quad (7)$$

where *NC/h* represents the uterine contractions per hour, *NC* is the total number of identified contractions, *L* is the signal length and F_s is the sampling frequency.

2. Database

We tested the software tool using CTU-UHB Intrapartum Cardiotoco-graphy Database, a public CTG recordings database available from Physionet.org. The database was collected between 2010 and 2012 by the combined efforts of the Czech Technical University of Prague and the University Hospital in Brno (Czech Republic) (18). The database contains 552 cardiotocographic recordings, each approximately 90 minutes in length, sampled at a frequency of 4 Hz. FHR and UC signals were acquired during labor, using intrauterine sensors. Each recording also has an annotation file that contains clinical and fetal outcome data such as delivery type, fetal gender and weight at birth, artery blood sample parameters (pH value, base excess or BDecf) and Apgar score.

We eliminated 24 recordings from the database because of a high signal loss ratio (the ratio between the number of samples equal to 0 and the total signal length) (19). The threshold value was set at 50%, meaning that recordings that had a signal loss ratio higher than the threshold value were eliminated from testing.

The recordings were divided into two groups, based on the pH value. Thus, re-

cordings that have a pH value below 7.2 represent the pathological group or the acidosis group and recordings with a pH value over or equal to 7.2 represent the normal group. The acidosis group contains 166 CTG recordings and the normal group contains 362 recordings.

EXPERIMENTAL RESULTS

The purpose of these tests is to establish if we can obtain consistent results, using previously described analysis software, for the identified parameters: Acc/h, Ldcc/h and NC/h that can allow us to identify similarities within the same recordings group (normal or acidosis) and differences between groups (normal and acidosis).

The first step was to determine the values for analyzed parameters for both groups. The results are presented in figure 7 for Acc/h, figure 8 for Ldcc/h, and figure 9 for NC/h.

For prolonged decelerations, given the significance of this pathological event and the rarity of its occurrence, we determined the number of recordings which presented prolonged decelerations. We found only 7 cases with prolonged decelerations in 362 normal recordings (1.7%), while in the acidosis group, from 166 pathological recordings we found 17 recordings that present prolonged decelerations (10.2%) (Fisher's exact test, $p<0.001$).

The second step is to determine the data dispersion within each group and to determine the value for each parameter.

Based on the values obtained for the parameters for both groups we compute an unpaired Student's t-test with a probability value $p<0.05$ to identify if the groups are statistically different (20) (fig.10-13).

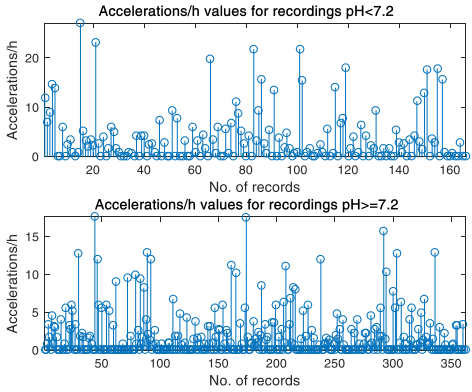

Fig. 7. Accelerations/h values for both recordings groups.

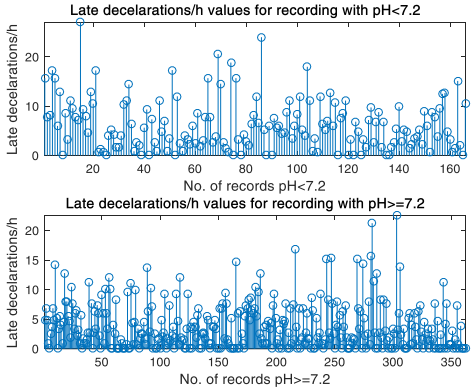

Fig. 8. Late decelerations/h for both groups (normal and acidosis)

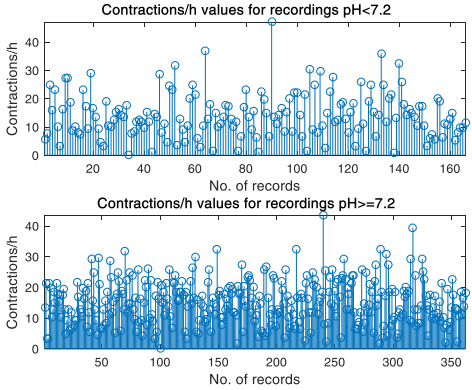

Fig. 9. Number of contractions/h for both groups

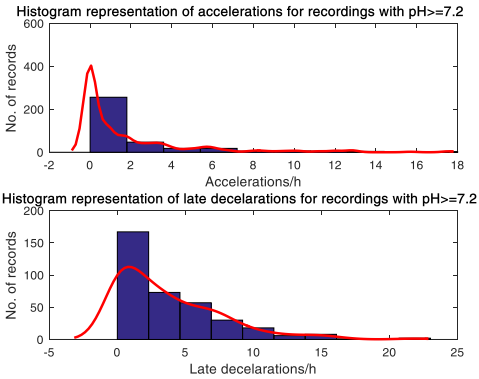

Fig. 10. Histogram representation of the recordings in the normal group for the parameters Acc/h and Ldcc/h

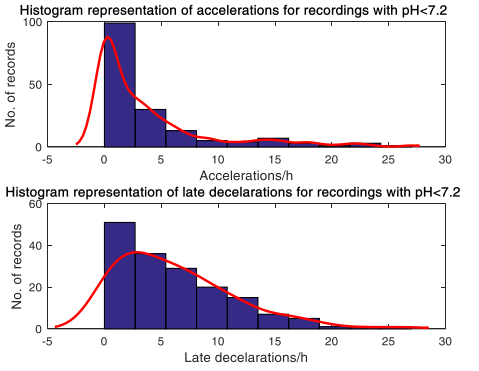

Fig. 11. Histogram representation of the recordings in the acidosis group for the parameters ACC/h and Ldcc/h

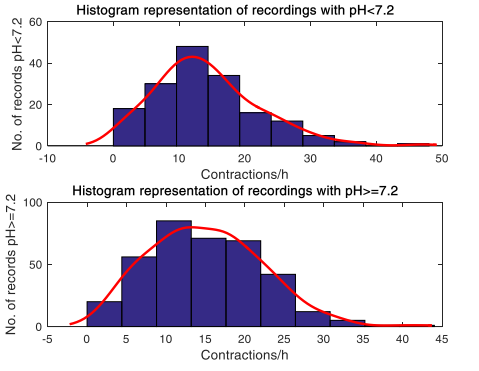

Fig. 12. Histogram representation of both groups for the parameter NC/h

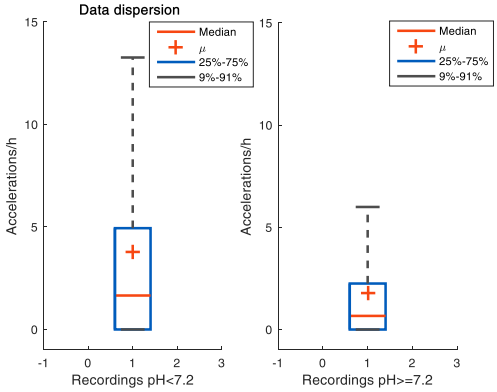

Fig. 13. Data dispersion for both groups when analyzing the Acc/h parameter

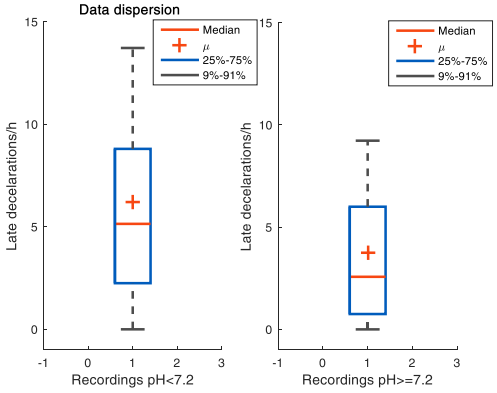

Fig. 14. Data dispersion for both groups when analyzing the Ldcc/h parameter

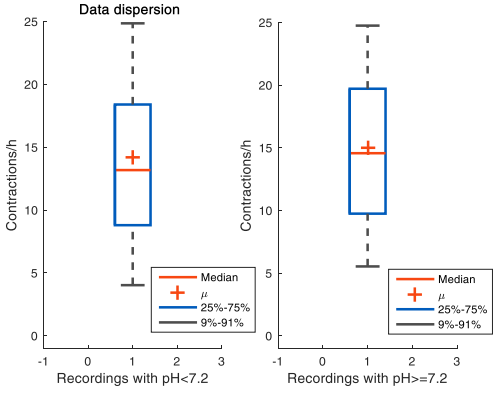

Fig. 15. Data dispersion for both groups when analyzing the NC/h parameter

The results presented in Table I are expressed as mean value ± standard deviation for each group. Table I, figures 14 and 15 show that the data groups are statistically different for the parameters Acc/h and Ldcc/h. The number of contractions per hour was not significant different between two groups. This is an indication that the NC/h parameter does not interfere in metabolic acidosis development.

TABLE I

Unpaired **Student's t-test** results expressed as mean ± standard deviation

Parameter	p	Metabolic acidosis group	Normal group	SD
Acc/h	0.016	3.77 ±5.42	1.8 ±3.05	3.95
Ldcc/h	0.022	6.22 ±5.2	3.73 ±3.91	4.36
NC/h	0.21	14.17 ±7.95	15.02 ±7.08	7.36

CONCLUSIONS

We developed and implemented a Matlab software used for CTG analysis, respectively identification of accelerations, decelerations and uterine contractions.

These parameters are used as indicators for the onset of acidosis.

The software was tested using a public database of intrapartum CTG recordings. We found a statistical difference for ACC/h, Ldcc/h and incidence of prolonged decelerations. However, the number of uterine contractions per hour of CTG trace were a constant parameter for the entire database and did not influence directly the onset of acidosis.

COFFEE INTAKE DECREASE THE MULTIPLE SCLEROSIS RISK

Health benefits and health risks of coffee drinking were evaluated by numerous studies that used human or animal models. Some studies have linked coffee consumption with neuroprotective effects by decreasing inflammation and demyelination.The influence of coffee consumption on the risk of multiple sclerosis (MS) has been investigated in two retrospective case–control studies conducted in Sweden and the US. Both trials included people aged over 15 years who were diagnosed with MS and have investigated consumption habits of caffeinated coffee in different periods of age. The two studies have involved a total of 2779 cases and 3960 controls. The risk of MS among participants which consumes coffee was compared with the risk of MS among participants who never drank coffee, by calculating ORs with 95% CIs.The results showed a reduced risk of MS among those who reported a consumption of coffee exceeding 6 cups daily (OR 0.70 in the Swedish study, and OR 0.69 in the US study) in comparison with participants who never drank coffee.Additional studies are needed to determine which of biologically active constituents of coffee determines these results, in order to use them in multiple sclerosis therapy (A K Hedström; E M Mowry; M A Gianfrancesco; X Shao; C A Schaefer; L Shen; T Olsson; L F Barcellos; L Alfredsson. High consumption of coffee is associated with decreased multiple sclerosis risk; results from two independent studies. *Neurol Neurosurg Psychiatry* 2016;87:454-460).

PATTERNS OF ROAD TRAFFIC ACCIDENT IN NORTH-EAST ROMANIA (Abstract): Romania is ranked first among mortality road traffic accidents in Europe. The **aim** of our study was to evaluate some statistical patterns of population group who unfortunately was admitted at an emergency hospital of Iasi, a large city in the North East of the country. **Material and Methods**: The study was performed on 1623 patients admitted in the Emergency Room ("Sf. Spiridon" Emergency Hospital of Iasi, Romania) suffering from road traffic accidents, during 2009 and 2013. **Results**: The prevalence of 19-45 age group cases represented more than 50% of all patients, with a high significance ($p<0.05$), and men were involved more frequently (69.69%) than women (30.31%); most of the patients were injured while driving an automobile; 6 PM was the "rush" hour (6.4%), Monday was the "black" week day (16.02% of total cases), September the "harvest" time (12.7%), and Summer the "hottest" season (48.49%). **Conclusions**: The "B plan" is imperative to be implemented in Romania, including **b**etter roads, **b**etter vehicles, **b**etter legislation, and **b**etter teens' education, in order to avoid road traffic accidents. **Keywords**: ROAD TRAFFIC ACCIDENT, INJURY, PEDESTRIAN, DRIVER.

Road traffic accidents are an important public health problem in all regions of the world, but especially in less and medium developed countries, which can be showed by a large and increasing number of deaths in these territories. In Romania, the road traffic accidents, resulting in injuries, are also a major health problem, representing: the first cause of premature death - PYLL (Potential Years of Life Lost) in males; the second cause of temporary disability (13.2% of a total); the fourth cause of death after cardiovascular diseases, tumours, and respiratory diseases; the fourth rank in adjusted life years' potential inability - DALY (Disability Adjusted Life Years); 6-7% of all hospitalized patients (1).

The risk of death from road traffic accidents in Romania is almost 14 times higher than the European countries average, Romania is ranked first among mortality road traffic accidents in the EU. The degree of civilization in a society is given also by the manner of the road traffic. Although human, material and social losses are huge, there are some interesting differences between countries in how they manage this problem. In some regions in Australia, Europe and North America, the number of deaths decreased from (25-30)/100,000 inhabitants in 1970 to (3-8)/100,000 inhabitants nowadays, although the number of cars has increased 5

times. These countries are not the richest, but they have created a safer traffic environment through traffic education, access to safe vehicles, and severe laws (2).

MATERIAL AND METHODS

The study was performed on 1623 patients admitted in the Emergency Room ("Sf. Spiridon" Emergency Hospital of Iasi, Romania) suffering from road traffic accidents, during 2009 and 2013. 902 patients (55.58%) were from rural areas, 721 (44.42%) from urban areas.

Scale types of variables presented in our research were nominal and ordinal, so they were analysed with *t* student-test. Statistical significant difference was at $p<0.05$, and confidence interval (CI) higher than 95%. The database was performed using MS EXCEL 2010 software and SPSS for Windows (version 16.0, SPSS Inc., Chicago, Illinois, USA) for statistical analysis of the collected data.

RESULTS

Annual incidence rates of road traffic accident showed ***increasing values in North-East Romania*** (fig. 1).

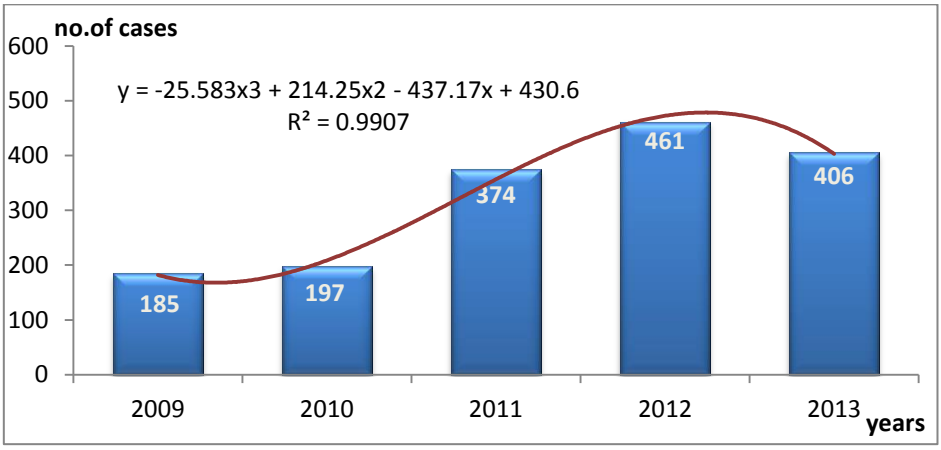

Fig. 1. Annual incidence rates of road traffic accidents

Comparing the five age groups recommended by the WHO, the annual prevalence values showed no significant differences, except for the age group under 18, because of their admission to "Sf. Mary" Emergency Hospital for Children, in Iasi. When assessing cumulative demographic range ***19-45 years old***, the prevalence of cases assisted in the ER represented more than 50% of all patients, the difference with other age groups was highly significant ($p<0.05$) (tab. I). The values series had a normal Gaussian distribution and Kolmogorov-Smirnov test was $p<0.01$ for each of the five years included in the study.

Statistical analysis showed a significantly higher percentage of ***male patients*** 1131 (69.69%) in relation to female patients 492 (30.31%) (t Stat = 2.33; $p<0.001$), from a total of 1623 persons.

The distribution by week day of road traffic accidents in Iasi showed that ***Monday*** was the "black" one (tab. II). Most of the patients were injured while driving an ***automobile*** (t Stat = 3.36; p=0.0199) (tab. III).

TABLE I

	No.	**%**	**No.**	**%**	**No.**	**%**	**No.**	**%**	**No.**	**%**
≤ 18	30	16.2	30	15.2	33	8.8	36	7.8	25	6.2
19-30	36	19.5	58	29.5	116	31.0	133	28.9	96	23.6
31-45	49	26.5	42	21.3	83	22.2	121	26.2	103	25.4
46-60	42	22.7	37	18.8	71	19.0	78	16.9	88	21.7
≥ 61	28	15.1	30	15.2	71	19.0	93	20.2	94	23.1
Total	**185**	**100**	**197**	**100**	**374**	**100**	**461**	**100**	**406**	**100**

TABLE II

Number of injured patients in motor vehicle accidents - by day of injury

Days of the week	Number of injured patients	
	No.	**%**
Monday	260	16.02
Tuesday	252	15.52
Wednesday	244	15.03
Thursday	187	11.52
Friday	222	13.67
Saturday	231	14.23
Sunday	227	13.98
Total	1623	100.0

t Stat = 23.86; $p<0.001$

TABLE III

Types of vehicles' occupants

Victims	No.	%
Pedestrian	301	22.68274
Motorcyclist	91	6.857573
Bicyclist	118	8.892238
Occupant of a car	473	35.64431
Driver	234	17.63376
Carter	110	8.289375
Total	1327	100.0

t Stat = 3.369146093; P(T<=t) two-tailed = 0.019908236

It is noted that a third of all victims recorded during the five years' analysis occurred in the ***summer*** season (48.49%) (fig. 2).

An evident assignation of months with the lowest frequency in road traffic accidents was not really possible. The incidence of occurrence of these accidents could not be linked to a specific cause so that the possibility of an appropriate interpretation is reduced. The "black" months in terms of an increased admission of injured persons were: ***September*** with 12.7% of cases, then August and July, with 11.6% and 10.7%, respectively (t Stat = 9.361431241; p<0.0001). This situation could be justified by the peak period of holiday and the beginning of school and university studies (tab. IV).

The daytime most involved in the occurrence of road traffic accidents was 18 hours (6.00 PM) (fig. 3).

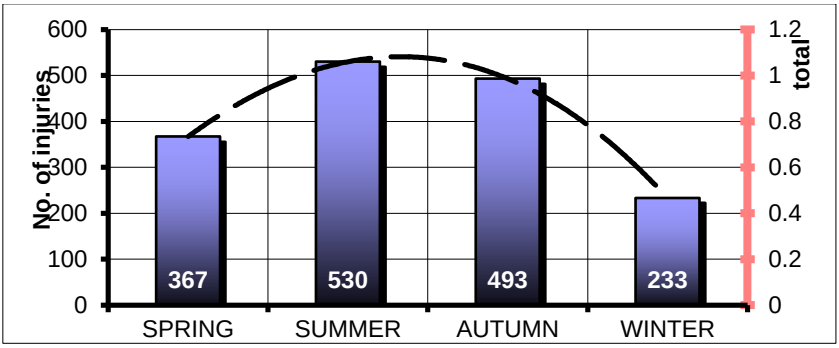

Fig. 2. Cases distribution in relation with seasons

DISCUSSION

Regarding the data of those who were involved in road crashes, our analysis showed significant differences between females and males in injuries rates. Authors of some studies such as Holland et al. (3), Bíl et al. (4), Pino et al. (5), and Valent et al. (6) explained a higher mortality rate in males than in females.

In countries with distinct seasons, there are differences between the incidences of road traffic accidents at different times of the year. Dynamic for the distribution of road accident victims is characterized by almost constant and continuous increase in the number of this category of victims, between spring - summer – autumn. The general trend of the prevalence and mortality caused by road traffic accidents can be divided in two cycles: first, an ascendant uniform cycle, characteristic for spring-autumn period; second, a descendant abrupt cycle characterized for winter-spring period. Specific factors of variations in the incidence of accidents in relation to the seasons have certainly taken into account in any epidemiological study of traffic accidents.

Many factors come to explain increased values of the prevalence of road traffic victims among the 19-45-year age group, with a significant increase in males. Among the most frequently listed are: the number of male drivers is larger and therefore the risk is higher; women drive more cautiously, avoiding speeding and paying more attention to signs and restrictions on movement; young people are frequently involved in traffic, both as pedestrians and as drivers (7, 8, 9). Showmanship, drinking, ignoring the legislation, recklessness, excessive speeds, a.s.o., make the road pathology a disease of multifactorial etiology and a major problem of public health in many countries (10, 11).

CONCLUSIONS

To know the real impact of road traffic accidents would facilitate the adaptation of emergency rooms to the annual increasing rate of incidence and allow the medical staff to be more determined to wait for, to diagnose and to treat medical and surgical emergencies. More effective national programs for primary prevention of road crashes could be implemented starting from the performed data.

The “B plan” is imperative to be implemented in Romania and elsewhere, including **b**etter roads, **b**etter vehicles, **b**etter legislation, and **b**etter teens’ education, in order to avoid road traffic accidents.

NEWS

HEPATECTOMY FOR GASTRIC CANCER METASTASES OFFERS SUPERIOR SURVIVAL

The liver is one of the most common sites of gastric cancer dissemination. There isn't any consensus regarding the benefits of the hepatectomy of gastric metastases. The authors review in a retrospective study 107 patients with hepatic metastases (34 synchronous, 73 metachronous) out of 5437 patients diagnosed and treated for gastric cancer in the Toranomon Hospital, Tokyo, Japan, between 1985-2014. Hepatectomies were performed in 9 synchronous and 4 metachronous metastases, that had ≤ 3 tumors and diameters < 3cm. The overall survival rates after hepatectomy were significantly improved in both synchronous and metachronous, compared with patients who did not undergo hepatectomy and had similar metastatic status. The multivariate analysis reveal that the hepatectomy is the most significant prognostic factor regarding the treatment of metastases, provided they are equal or less than 3 and smaller than 3 cm (Ohkura Y, Shinohara H, Haruta S et al.Hepatectomy Offers Superior Survival Compared with Non-surgical Treatment for ≤3 Metastatic Tumors with Diameters <3 cm from Gastric Cancer: A Retrospective Study., *World J Surg*. 2016;39(11):2757-63. doi: 10.1007/s00268-015-3151-0).

CONSIDERATIONS ON ANATOMY AND PHYSIOLOGY OF LYMPH VESSELS OF UPPER AERODIGESTIVE ORGANS AND CERVICAL SATELLITE LYMPH NODE GROUP (Abstract): The almost constant local regional development of the cancers of upper aero digestive organs requires the same special attention to cervical lymph node metastases, as well as to the primary neoplastic burning point. The surgical therapy - alone or associated -has a mutilating, damaging character, resulting in loss of an organ and function, most of the times with social implications, involving physical distortions with aesthetic consequences, which make the reintegration of the individual into society questionable. The problem of cervical lymph node metastases is vast and complex, reason why we approached several anatomical and physiological aspects of lymph vessels of the aero digestive organs. Among the available elements during treatment, the headquarters of the tumour, its histologic degree, and its infiltrative nature, each of them significantly influences the possibility of developing metastases. **Keywords**: TOPOGRAPHIC ANATOMY, EMBRYOGENESIS, LYMPH NODES, HEADQUARTER OF TUMOR, HYSTOLOGIC DEGREE, INFILTRATIVE NATURE.

Taking into account the fact that the lymph from the entire body drains into the large vessels on the base of the neck, the research area of specialties extends in other medical fields too, in the event that the primary lesion is not detected in the head and neck.

Our knowledge on lymphatics of the neck is based on the works of Barteis, Iosipow, Kessel, and Octaviani, and especially on Rouviere's descriptions which are nowadays the starting point of study for every specialist (1).

On the basis of 600 various jugular carotid dissections, it results a description of position of pathologic lymph nodes, that is useful for completions on neck dissection (2).

General embryogenesis concepts

The lymphatic system is born phylogenetically and ontogenetically later than the blood system. Starting with the third embryonic month, the lymphatic meshwork communicates with right and left upper cardinal vessels through an orifice equipped with a valve. In the place where the lymph nodes will be formed, bundles of vessels appear, in whose loops mesenchymatous elements gather, lymph cells

arise, and the fibrous capsule is already shaped in the fifth month (3).

From marginal sinuses lymph vessels grow, which penetrate the parenchyma towards the hilum. At birth, the lymph nodes are formed organically, except for the ones that are born secondarily, postnatal. The weight of the lymph node system is 1% of the body weight.

This tissue is best developed around the age of 14-15 years old, coinciding with the complete growth of the adrenal gland (4).

From here on, it starts a slow atrophy process, stronger and stronger as years pass. There won't be a total regress, since they can react inflammatory or neoplastic any time, outreaching their initial volume (5).

General structural features of vessels and cervical lymph nodes

The cervical lymph system is formed of lymph vessels and capillaries, lymph nodes, and terminal collectors on the base of bilateral neck. As Rouviere (1) described, each lateral cervical area contains 23 - 48 lymph nodes (1).

Zechner believes that 1/3 of the total of approximately 400 lymph nodes in human body is located in the neck (6). Royster, dissecting the operatory parts of 39 radical neck dissections identifies, through histologic studies, lymph nodes of various sizes, ranging from 1 cm to 1.5 mm in diameter. Under these conditions, in a cervical dissection, approximately 146 ganglionic formations are collected. It is remarkable that the lymph nodes that were detected microscopically were found metastasized, therefore several authors concluded that the ganglionic dissemination is not directly proportional to their size (7).

In normal physiological conditions, lymph nodes are usually bean-shaped, smooth, soft and elastic. Structurally, they are surrounded by a fibrous capsule, and inside there are parenchyma areas: the outer cortical area and the inner medulla (3). The lymphoid tissue is organized in follicles in cortical area and follicular cords in medulla, being formed of a reticule in which there are lymph cells (lymphoblasts), which will generate lymphocytes. The capsule sends interfollicular septa through the cortical area, which are continued in medulla through intercordonal septa up to the hilum (6, 7).

The circulation pathways of the lymph into the lymph nodes are perifollicular sinuses in cortical area and cavernous pathways in medulla. Lymph capillaries are made of a single endothelium and form a network of various density in connective tissue. The lymphatic vessels have a thicker own wall and double valves, bond, open in the direction of the stream and separated by a distance of approximately 1-2. The lymph trunks have, like blood vessels, an intimate layer, the endothelium of the vessel, a medullar layer, formed of smooth muscle fibres, and a connective-elastic layer, called adventitia, more reduced. (7).

Lymphatic circulation and functions of lymphatic-ganglionic system.

There are several causes of the progress of the lymph into the lymph vessels, depending on their place.

According to Rouviere, in the area of head and neck, there are two important elements (1): the arterial element, which, during systole sends the arterial beat to the cerebrospinal fluid which sends it further to the lymphatic vessels of the meninges. The absorption power of the lymph vessel during diastole should not be neglected; the

respiratory element is also valuable for circulation within veins, where the thoracic suction is the main factor of blood progression, therefore of lymph progression (3).

Unlike the large descending cervical and thoracic veins, lymphatic vessels have valves that prevent the retrograde circulation, due to higher downstream pressure than the upstream one, the opposite of venous circulation. The pressure in the thoracic duct increases while expiring and decreases while inspiring. Research conducted by Rouviere and Valette on dogs reveal values of 6 cm^3 water, therefore a higher value than the venous pressure of large vessels on the base of the neck, to ease the passage of the lymph into blood (1).

Lymphatic collecting vessels reach the closest lymph nodes, according to Bartels' law, and, crossing the capsule, open in the marginal sinus. Other times they travel in remote ganglionic relays or the afferent and efferent vessel, or are closely and directly bond through a medullar sinus (3).

All these data may explain why a metastasis does not always undergo all dissemination stages of lymph nodes.

Lymphatic vessels exiting through hilum are afferent lymphatics, but the direction of the stream can change backwards towards lymph nodes, in certain pathological conditions, and then the metastasis might initially arise on hilum. The lymph does not bathe all the parts of the marginal sinus, therefore subcapsular parcelar metastases are possible. Direct links between lymph vessels and veins are rare; only exceptionally a lymphatic vessel can open in thoracic duct. A very important practical aspect, according to Pressman (quote 6), is the direct communication between lymph nodes and blood vessels. Inserting successively air and saline in the lymph nodes of a dog, Pressman observed a direct communication between the lymph nodes and are neighbouring blood vessels, due to the existence of a reach capillary plexus within the lymph node (1,3).

Many remarks revealed that the pressure needed for such substance to enter the blood is lower than the one needed to enter the efferent canals of the respective lymph node. In some cases, the presence of neoplastic cells in blood flow, especially in the area of the lesion, can be thus explained. Lymph is in a diffusion balance with interstitial fluids, respectively with blood plasma, in which the electrolytes, organic and inorganic substances differ little from the ones in blood plasma, except for the concentration of albumin. The walls of lymphatic capillaries are highly permeable and allow diffusion of large molecules and corpuscular tissues, so that lymph is able to transport plasma proteins from interstitial fluids into the blood, regulating the register of plasma albumin. In 24 hours, almost the entire quantity of plasma travels through blood capillaries into interstice, where they are sent back to the lymph. There is a so called lymphocrinia, when some of the secretions of endocrine glands, whose structure contains albumin, reach the general circuit through lymph vessels. Via the thoracic duct, in 24 hours, approximately 2-3 litres of plasma albumin travel, leading to an important loss of lymph during lesions of thoracic duct, with dehydrating effect, with a dangerous deficit of serum albumin; this is also possible during neck dissection on the base of the neck (3).

Lymph nodes have a several functions; the most important ones are:

- *Lymphopoiesis.* Through their structure, lymph nodes are the most important

and the most spread wearers of the lymphoreticular tissue. This tissue has a great capacity of cell genesis and formation of lymphocytes which float into the lymph in various mononuclear aspects and from here partially in blood, where they regulate the formula of blood. Formation and number of lymphocytes are regulated by the hormones of the adrenal gland. Hypofunction of this gland causes lymphopenia, while an increase in number of adrenocorticotropic hormones or the action of various stress factors causes lymphocytosis (3).

- *Formation of antibodies.* In 1898, Pfeiffer and Mark (quote 7) showed that inside lymph nodes there are antibodies against the choleric vibrio and that in general the titre of the antibodies is higher than the titre of afferent lymph vessels. Recent research has proved that only certain immunologic substances are formed in lymph nodes, together with some of the gamma globulins of plasma proteins, namely, in plasma cells (8).

- *Ant infectious and antitumor filter*. In 1860, Wirchow described the barrier function of the lymph nodes, afterwards extending this function for toxins, various particles, bacteria, and tumour cells (9).

This complex function materialises in three aspects: spasms of lymph vessels: Fuldi et al. showed that in the centre of the inflammation, the lymph vessels are clogged by a fibrin clot and distal from it there is a functional closure, a spasm (10). No doubt that the closure of the lymph pathways as a result of inflammatory oedema prevents the entrance of the toxins and bacteria in inflammatory burning point into the blood; the lymph that reached the marginal sinus and then in other intraganglionic directions decreases the circulation speed and changes the dynamics of circulation. The reticulum of sinus endothelium and the other free reticula enhance this stopping mechanism for foreign bodies, bacteria, and tumour cells. The reticular cells, fixed or free, start an active phagocytosis which becomes the main element of defence (3).

These defence mechanisms of lymph nodes can be overcome through the increase of the harmful action of foreign agents and, moreover, they themselves can become infectious or tumoral burning points of spreading.

It seems that not all researchers agree to the role of ganglionic filter. Thus, Pressman (11), conducting research on animals, stated that in reality, lymph nodes have the structure and function of a sponge, and that a mere pressure is enough to express the content, not only in efferent vessels, but also in the blood flow. As a result, during a clinic examination or a neck dissection, one should avoid the compression of suspect lymph nodes, which might contain malignant cells.

The problem of ganglionic filter was raised in order to decide whether to avoid or not the cervical neck dissection. An increase of frequency of metastases was noticed, and researchers concluded that the cervical lymph nodes are a barrier against dissemination of metastases; the lymph nodes can delay individually or as a group the cranial-caudal lymphogenic metastatic process.

Multiple research and clinical observations prove the existence of a defence function, but evidence of destroying the neoplastic cells in the lymph node, as well as a cancericidal function are missing. (11).

The lymph meshwork is extremely developed in the area of inferior and middle nasal fossae, olfactory area and around the

choana. The olfactory area communicates with the subarachnoid spaces through the lymph vessels which accompany the fillets of the olfactory nerve.

The lymph collecting vessels are directed towards the tubular area, receiving also the lymphatic vessels from the upper side of the veil, after which two pedicles are formed: an external pedicle, which criss-crosses the styloid process and discharges into the main digastric lymph node (Kuttner); a posterior pedicle, more important, which crossing the superior constrictor muscle, drains in Gillete's retropharyngeal lymph nodes, and after their involution – in the lateral retropharyngeal lymph node in posterior subparotid space. The lymphatics of the sinuses and ethmoidal cells are associated with the ones of the nasal fossae and follow the same destination.

The lingual lymph network is particularly rich and it is grouped in median and lateral collecting vessels. The median lymphatics travel down towards the median glossoepiglottic fold, where, changing direction towards the lower pole of the palatine tonsil on the same or opposite side, meet the lateral lymphatics (12). From here, together, they cross the lateral wall of the pharynx at various heights and in the end they become: some of collecting vessels in Kuttner's or Most's subdigastric lymph node; some in the middle jugular lymph node; some in the median lymph node of the spinal chain. Remarkable is the wide array of lateral and heterolateral spreading of lymph nodes of the lymphatics of the base of the tongue, as well as the connections with the lymphatics of the palatine tonsil on its lower pole (10).

Inside the pharynx, the mucous membrane is spread along the entire pharynx, very rich within the piriform sinuses and around Waldeyer's ring; establishes connections with the lymphatics of the nasal fossae, oral cavity and larynx in the anterior side, downwards connections with the lymphatics of the esophagus and outwards, with Eustachian tube network (13,14).

The collecting vessels are grouped depending on the three distinct regions (nasopharynx, oropharynx and laryngopharynx), with different directions and ganglionic destination.

The lymph on the walls of the nasopharynx is collected in two categories of collecting vessels, median and lateral. The median vessels originating on the floor, Luscka's tonsil and the posterior wall are the most numerous ones. They cross the two large anterior muscles of the head, tilt outwards and reach the lateral retropharyngeal lymph nodes. Some vessels avoid this stage and end in superior external jugular nodes or lower, in a spinal or subdigastric lymph node; the counter-lateral and bilateral drainage is possible. The lateral lymph vessels cross the superior constrict of the pharynx and discharge in the lateral retropharyngeal lymph node.

The collecting vessels of the oropharynx are grouped in the lymphatics of the palatine velum, palatine tonsils and the pillars of the palatine velum; very rich on the anterior side of the velum, especially on uvula. The collecting vessels have three directions: an anterior lymphatic path, which joins the lymphatics of the cheek and goes downwards to pre- and retrovascular submandibular lymph nodes; a median pathway, which criss-crosses the deep side of digastric muscle and ends in subdigastric lymph node and superior homolateral and counterlateral jugular lymph nodes; a posterior pathway, where they join

the lymphatics of the posterior pedicle of the nasal fossae and end in lateral retropharyngeal lymph node and sometimes in the counterlateral lymph node. There still are connexions between lymphatics of the velum and lymphatics of the palatine tonsil (15).

The lymphatics of laryngopharynx are numerous and large, and, especially on the piriform sinuses, they are grouped as: anterior collecting vessels, which, together with the lymphatics of the supraglottic area of the larynx follow the superior laryngeal pedicle and distribute to subdigastric lymph node or lower, to jugular lymph nodes, located between the thyrolinguofacial and omohyoid trunk; posterior collecting vessels cross the lateral pharyngeal wall and end in lateral retropharyngeal lymph node or superior exterior jugular lymph node (15).

Reference to cervical esophagus alone is arbitrary, due to the fact that the lymph network of the esophageal mucosa is continuous, so that it can drain both into a neighbouring lymph node, and into a lymph node located at a distance from the emission site of the lymph (16, 17).

The deep lymphatic network of the larynx is separate from the counterlateral one by a fibrous commissure that joins the two halves of the thyroid cartilage, distinct in embryonic terms.

The laryngeal lymphatic pathways are linked to the one of the barrier of the tongue and pharynx. As a general remark, the direction of the lymph stream goes upwards from the inferior margin of the cricoid.

Lymphatics of the trachea, although making connections with the subglottic lymphatics, drain especially towards the mediastinal lymph nodes; a subglottal cancer, extended to trachea, will need the therapy of the structures of the neck simultaneously with the therapy of the mediastinum.

Subglottic lymph vessels which receive a small portion of the lymphatics of the vocal cords are connected with the supraglottic lymph vessels through the posterior wall mucosa of the larynx and very few ventral connections (16).

Rejecting the idea according to which the lymph nodes are randomly spread in soft parts of the neck, they form a fixed, well-structured anatomical whole, enough and often complete for stopping any kind of aggression of the lesions of upper aerodigestive organs.

The anatomic study of these groups of lymph nodes is indispensable for understanding the pathogenic concept of cervical lymphadenopathy and for defining the physiologically normal direction of the lymphatic stream (4).

It is necessary to know them, each time a cervical lymph node dissection is performed, be it radical or traditionally functional (2,3).

For practical purposes, without ignoring the continuity of lymphatic system, the surgical anatomy describes several chains of lymph nodes, identified through certain limits, bones or muscles. Neck dissection contains certain chains which, in general, may fit certain geometrical shapes, so that the piece contains a coherent assembly whose sides are dissected (4).

Even if there still are some concerns related to cancerogenic factors, the lymphatic system looks like a unitary whole of performant pathways, which offers the tumour a way to evade, and the tumour will definitely follow it.

Histological research of the tumoral peripheral areas reveals a stroma, a pericarcinomatous reaction which does not limit or

cease the process. Thus, there are inflammatory (granuloma), constructive (connective tissue hyperplasia), and vascular phenomena (vascular neoformations), insufficient as barriers, which allow the effraction of tumoral cells from the local cohesion, which will borrow whatever dissemination pathway they find (17, 18). The lymphatic discontinuity causes embolism, usually in the lymph nodes of the first relay, the closest to tumour. They have a clinical and diagnostic importance because through their topography they are able to detect the headquarters of the primary lesion.

This rule is not absolute, since there are also abnormal pathways, or by blocking the existing pathways of previous inflammatory processes, the drainage takes place through collateral pathways. One needs to take into account the cross drainage, which can cause counter lateral metastases, solitary in 10% of the cases (19).

Hematogenous discontinuity pathway can usually provide the metastases of sarcomatous tumours and malpighian carcinoma in 45% of the cases.

Continuity pathway presented as neoplastic lymphangitis is observed along the preformed lymph vessels through the lymph sheathes of the nerves (10,15).

Morphological changes of the lymph nodes which are macroscopically visible for the clinician are reactive changes of the lymph nodes, tokens of defence of the reticular endothelial system, characterized by nonspecific reactions which are prone to produce a spontaneous closure of the lymphatic pathways during acclimation of the tumoral cells which reached the marginal sinus, and tumoral changes of the lymph nodes.

Related to reactive changes of the lymph nodes and the way the metastases approaches the lymph node, the most frequent way of dissemination is the orthograde way, and the tumoral graft is located in the marginal sinus of the convexities of the lymph nodes (16, 19).

If a lymph node is blocked by a tumour or inflammation and it is excluded from lymphatic circulation, the afferent vessels enlarge, the stream becomes reverse and it drains randomly, involving tumour cells as well, which explains the appearance of the lymphatic invasion.

CONCLUSIONS

In our evaluations, we can conclude that when the high percentage of responsibility of the lymph nodes was confirmed by statistics, compromising the results through local relapse or remote general metastases, therapists' main point of interest lays in solving this problem; a cancer whose first treatment failed is definitely lost.

The treatment approach on cervical lymph nodes with metastases evolved in the same pace with the development of general oncology principles and especially cervical-facial cancerology.

A RENAISSANCE PROMOTER OF MODERN SURGERY (Abstract): The present paper aims, exploring the history of Renaissance medicine, to evoke the figure and work of the priest, surgeon and anatomist, Guido Guidi (Vidus Vidius) (1509-1569). The XVIth century is considered a period marked by artistic and scientific effervescence in the western part of Europe and Guido Guidi was a first order personality, grandson of Domenico Ghirlandaio and friend of Benvenuto Cellini. He was appointed by the King Francis I the first professor of anatomy and surgery at the newly founded Collège de France. On demand of the King, he wrote *Chirurgia è Graeco in Latinum conversa Vido Vidio Florentino interprete, cum nonnullis eiusdem Vidii comentariis* (1544), a beautifully illustrated original surgery book that became for the following two centuries the main source in teaching surgery. Our study realized a detailed assessment of the book and especially of its illustrations belonging to Francesco Salviati. Exploring the life of Guido Guidi, we were also able to point out other significant contributions in the field of anatomy and clinical medicine as *De anatome* the first book where are presented disarticulated, the bones of the skull base and also the discovery of the chickenpox. Some surgical personalities attributed to him both the elaboration of the term *appendix vermiformis* and the first description of an aneurysm, he treated with the help of Fallopio. Although forgotten today, Guido Guidi was a leading figure of the Renaissance medicine both in France and Italy. **Keywords:** GUIDI, SURGERY BOOKS, RENAISSANCE MEDICINE, SALVIATI, COLLEGE DE FRANCE.

At the beginning of the XVIth century Florence was the theater of major social and political convulsions occurring against the background of the economic prosperity and artistic effervescence at the peak of the Renaissance. The richness and patronage of the Medici family decisively contributed to the development of an unequaled Florentine artistic universe and to the apparition of brilliant masters and apprentices who scientifically studied the human body through dissection in order to achieve a realistic representation in works of art. This was the moment when the canons of anatomical drawing were established and the artistic anatomy began to be taught by cadaver dissection at the Arcispedale Santa Maria Nuova. Here Leonardo da Vinci (1452-1519) and Marcantonio della Torre (1481-1511) started to write a book with drawings

after dissection preparations but the plague of Florence (1511) interrupted this collaboration, due to the death of della Torre.

In 1540 was established, under the patronage of Grand Duke Cosimo I de Medici, the "Accademia degli Umidi", which later became "Accademia Fiorentina" (in 1541) (1). Here, anatomy was thought initialy by Cosimo Roselli (1439-1507) and later by his pupils, Piero di Cosimo (1462-1521), Andrea del Sarto (1486-1531), Domenico Ghirlandaio (1449-1494). This effervescent atmosphere marked by the enthusiastic desire for knowledge, developed the brilliant triumvirate Leonardo da Vinci, Michelangelo (1475-1564) and Benvenuto Cellini (1500-1571).

LIFE AND ACTIVITY

In this artistic Renaissance Florence was born, on February 10, 1509 (2, 3, 4). Guido Guidi, the son of the well-known Florentine physician Giuliano Guidi and Costanza Bigordi, daughter from a second marriage of the great painter Domenico Ghirlandaio.

The data of Guido Guidi's childhood and how he obtained his university degrees are missing (5), but it is believed that the young man, with artistic blood in his veins and raised by his father in the medical tradition required by the Hippocratic oath, received a humanist education of the highest quality. In the first phase of his life, until 1535, he studied in Florence, becoming a connoisseur of Greek and Latin. Given his high education and early erudition he was noticed by the Cardinal Ridolfi, who took him under his protection. In the Cardinal's entourage, the young Guidi had access to the famous Laurentian library that housed manuscripts of great value in all areas of science and art. Among them there was a codex of the Byzantine physician Nicetus from the X-th century, which contained, collected by Apollonius of Kitium, the Hippocratic works: *De ulceribus*, *De fistulis*, *De vulneribus capitis*, *De fracturis*, *De articulis* and *De officina medicinae*, the last three commented by Galen, in Galen's treatise *De fasciis* and Oribasus, *The laqueis and De machinamentes.*

Between 1535 and 1538, Guido Guidi went to Rome where he worked with famous surgeons of the time, Antonio Ponzanello and Giacomo Rastelli, the latter being the personal surgeon of Popes Clement VII and Paul III. Under the guidance of Roman masters he became familiar with the use of contention and continuous extension devices in the treatment of strains and fractures. It seems that in Rome Guido Guidi met for the first time Benvenuto Cellini and warm friendship developed between the two Great Men.

After returning to Florence, Cardinal Ridolfi encouraged Guido Guidi to translate *De ulceribus* and *De fistulis,* adding not only his own comments but also that of Aristotle (*causam nos docuit Aristoteles, quum tradit calorem in unu coactum augeri..)* and of Eudemus (370-300 BC), Cornelius Celsus (25 BC-50 AD), Paulus in Aegineta (625-690), and Soranus of Ephesus (ca. AD 98-138) (*Soranus, cuius scripta de vulneribus capitis adhuc extat...)* as is specified in *Chirurgia* pp. 67-72.

King Francis I of France informed by Primaticcio (1504 - 1570), by the diplomat Alamanni and by Cardinal Ridolfi himself about the audacious attempt of the young erudite, invited him to Paris in 1542. From that moment the life of Guido Guidi had sensationally changed. He presented to the King the original codex and his translation of it, making an incredible impression. He was appointed the first professor of medicine and surgery at the newly established

Collège de France, the personal physician of the King, and was requested to complete the translations in order to publish a book of surgery, according him important ecclesiastical benefits.

At Paris, where Guidi taught and practiced medicine between 1542-1547, for unknown reasons he changed his name, becoming Vidus Vidius as he will be cited in the classical anatomical literature, including *Nomina Anatomica*. We believe that the truth is more subtle; tempted by the advantages of belonging to the clerical elite, Guido Guidi, skillful user of Latin, Greek and Arabic, had chosen for himself this cognomen derived from "widower" or "alone", thus declaring his intention of becoming a priest. This idea is supported by at least two arguments: Tuscan contemporaries, including Cellini, continued to call him Messer Guido Guidi; in a pirate edition of *Chirurgia è Graeco in Latinum conversa* from 1553, the author was named Guy *i.e.* Guido the Widower (6).

In his private life, fate favored him again. The young Florentine became very good friend with Benvenuto Cellini who hosted him in his castle, Petit Nesle and, in his autobiography, made him an extremely flattering characterization. Here he met Pierre Galtier, the future editor of *Chirurgia è Graeco in Latinum conversa*, who worked in typography in the Paris castle of Benvenuto Cellini.

PAVLVS PP. III.

Nuerſis & ſingulis, quibus hæ noſtræ literæ præſentabuntur, Salutem & apoſtolicam benedictionem. Quùm ſicut dilectus filius Vidus Vidius Philoſophus Florentinus, Regis Chriſtianiſſimi Phyſicus nobis nuper exponi fecit ipſe ad communem omnium vtilitatẽ Hippocratis de vlceribus, de fiſtulis, ac de vulneribus capitis, necnon de fracturis, de articulis, & de officinâ medici, ac Galeni de Faſcijs, & Oribaſij de laqueis, aliúmque de machinamentis libros cum eiuſdem Galeni commentarijs in tres vltimos ex ſupradictis Hippocratis libris ab eo è Græco in Latinum conuerſos, cum cõmentarijs etiam, quos ipſe Vidus in tres priores Hippocratis libros deſuper expreſſos edidit, imprimi facere & emittere intendat. Nos ne alij lucrum ex alieno labore quærentes, ſumpto inde exemplo, dictos libros & commentarios in eiuſdem Vidi damnũ & prejudicium imprimant, prouidere, eiuſdémque Vidi indemnitati conſulere cupientes, eius ſuper hoc nobis porrectis precibus inclinati, omnibus & ſingulis Bibliopolis & librorũ impreſſoribus in vniuerſa chriſtianitate conſtitutis ſub excommunicationis latæ ſententiæ pœnâ, in noſtro verò & ſanctæ Romanæ eccleſiæ ſtatu mediatè vel immediatè ſubiecto commorantibus, etiam ſub amiſſionis librorum & centum ducatorum auri de Camerâ, pro vnâ Camerę noſtrę apoſtolicę, & pro aliâ medietatibus eidem Vido applicandorum pœnâ inhibemus, ne dictos libros & commentarios intra Decennium proximè futurum ſine dicti Vidi licentiâ imprimere, ſeu impreſſos vendere, aut venales habere audeant vel præſumãt. Mandantes omnibus & ſingulis locorum ordinarijs, & eiuſdem ſtatus noſtri gubernatoribus & officialibus, vt ad omnem dicti Vidi requiſitionem præſentes publicent, & eas iuxta ipſarum tenorem obſeruari faciant & curent, Iuris & facti remediis opportunis. Cõſtitutionibus & ordinationibus apoſtolicis, cæteriſq; contrariis non obſtãtibus quibuſcunq;. Datũ Romæ apud ſanctum Petrum ſub annulo piſcatoris Die ſexta Decembris M. D. XLIII. Pontificatus noſtri Anno Decimo.

Blo. El. Fulginen.

B

Fig. 1. A. Main opening page of *Chirurgia è Graeco in Latinum conversa*, decorated with the royal crown with the lilies of France. B. The papal prohibition against copying, reproducing or republishing the book (copyright) (7).

Guido Guidi became the first professor of medicine at the Collège de France, his clear and attractive public lectures on medicine and surgery, as well as his elegant style (also reflected in his writings) brought new students and a large audience and at their request he began to carry out public demonstrations of anatomy. He worked

intensively untill 1543 completing (fig.1) the book entitled *Chirurgia e Graeco in Latinum conversa, Vido Vidio Florentino, cum nonnulus eiusdem Vidii comentariis* (7).

It seems that the book was printed under the guidance of Benvenuto Cellini himself, as demonstrated by the analysis of the capital letters at the beginning of the chapters, in which can be seen the floral ornaments used by Cellini for the armor of Cosimo I de' Medici (8) (fig. 2).

Fig. 2. Capital letter from *Chirurgia è Graeco in Latinum conversa*, decorated with floral motifs that are found in Benvenuto Cellini, on the bronze bust of Cosimo de' Medici, *Museo Nazionale del Bargello* in Florence (7, 20).

Guidi presented the book to the King Francis I, requiring a protection against plagiarism and republication by others. The King wrote him an eulogistic foreword, calling him *"notre cher & bien ayme maistre Vidus Vidius de Florence, docteur en medecine, notre medecin ordinaire & lecteur en Paris"* and then he added " *nous a faict dire & remostrer, quil estoit apres avoir laisser a imprimer a ses grandz fiz, mises & depenz, & au gand proffit & promotion des estudians en medecine & principalement en la chirurgie ung liure intitule....pour le teps & terme de six ans prochainement venant a commencer du jour & date de ces presentes, autres imprimeurs ne puissent imprimer ne vendre ledict liure ensemble, ou par ses parties, que ceulx a qui ledict permectra"* establishing penalties and significant punishments for infringement of that prohibition. The royal document dated January 2, 1543 (7, p. 22 iij) is the first known written copyright. But the author was not satisfied with that. He presented the manuscript to Pope Paul III and received, after 10 months of thorough review of the book in the papal chancery, a brief preface that proclaimed the originality and usefulness of the book and prohibited the partial or total reproduction under the penalty of excommunication (7, p. 22 ij).

Chirurgia è Graeco in Latinum conversa that became a reference book for the study of surgery in the XVI to XVIII centuries, begins as a result of author's erudition, with a bilingual alphabetical index in Greek and Latin, where, across 14 pages, the correspondence of the surgery terminology is specified in both languages. Moreover, Guidi presents an index of authors and works, outlining that the first six chapters, *De ulceribus, De fistulis, De vulneris capitis, De fracturis, De articulis, De officina doctors,* belong to Hippocrates and are commented by Vidius (the first three chapters) and the following three chapters to Galen.

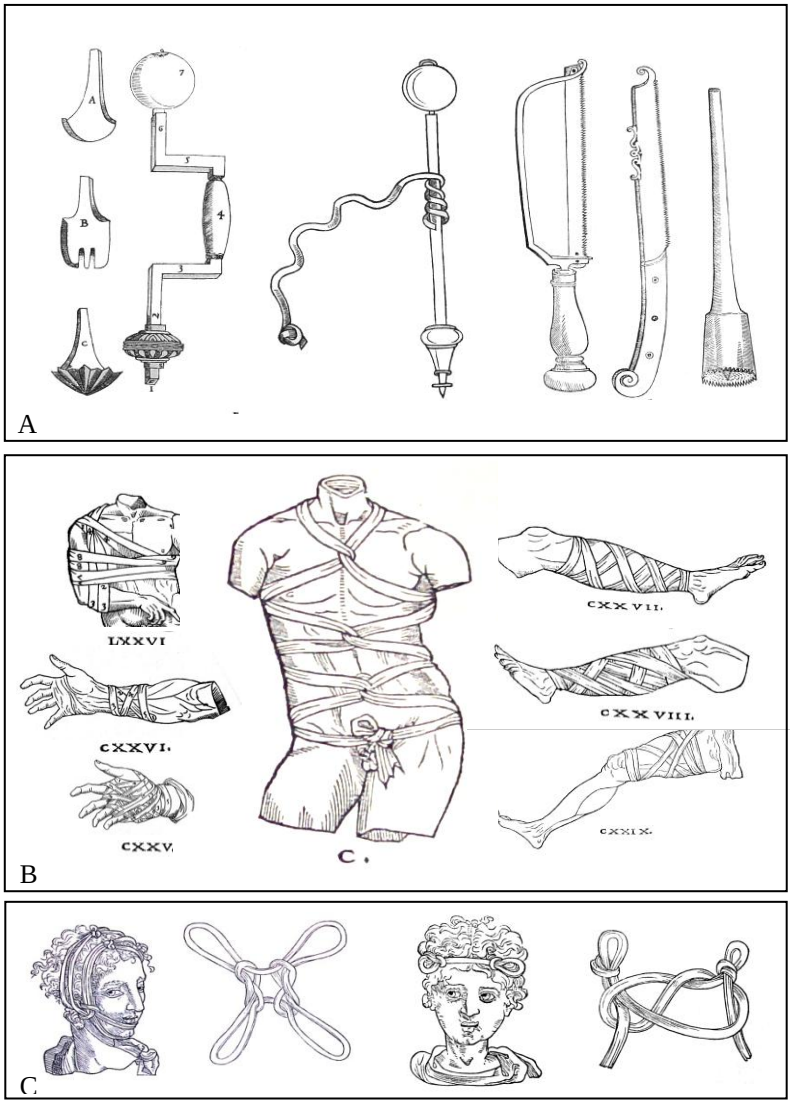

Fig. 3. A. The instruments imaged for different interventions on the bones (commentary illustrating *De fracturis*); B. Types of bandages for limbs and trunk; C. Models of surgical knots (7).

Chapter VII contains Galen´s *De fasciis,* and Oribasius´ *De laqueis* and *De machinamentes,* commented and illustrated by Vidus in collaboration with the Florentine painter Francesco Salviati (9) (fig. 4).

If, in the study of the six Hippocratic works, Vidus had only a theoretical contribution, the work of Galen *De fasciis* was richly illustrated with original designs of head bandages such as a complete capeline, single or combined with a gonion/chin double support sling, other types of bandages for craniocervical injuries, upper limb and thorax bandages, seen in

the Tabula LXXII, showing a shoulder immobilization technique used until today, such as the Desault bandage. Of the thoracoabdominal bandages, we mention the contention system used in the diastasis recti, where the bandages are arranged alternately, in the direction of the fibers of the oblique external and internal muscles of the abdomen and united in the midline as a raphe, which doubles the white line (fig. 3).

Of the periarticular bandages, the intercrossed pattern slings of the thumb, groin and talocrural bandages conclude the series of 138 drawings of the *De fasciis* chapter.

From the work of Oribasius (AD 320-403), Vidus selected, commented and supplemented the chapters on knots and orthopedic devices to reduce dislocations and fractures.

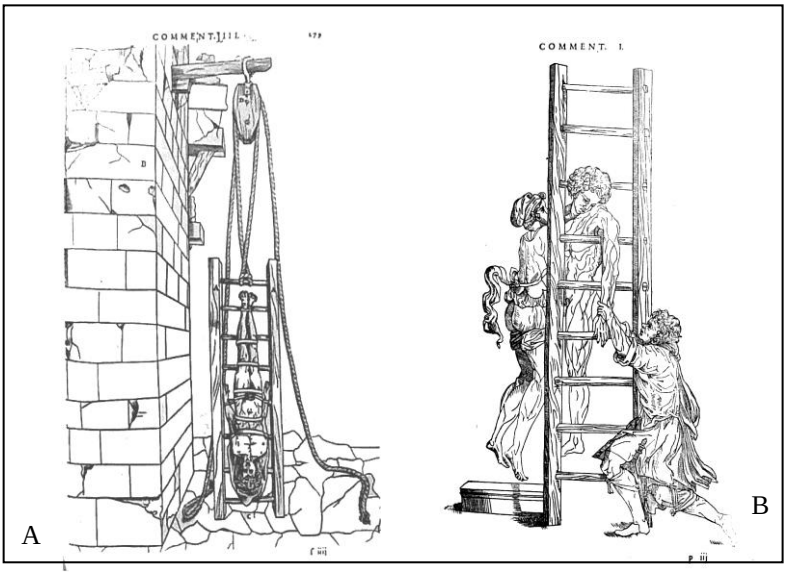

Fig. 4. Devices (machinamentes) for continuous extension (A) and luxation reduction (B) reproduced from original engravings of Francesco Salviati, preserved in Paris, at the Ecole Nationale Supérieure des Beaux-Arts, Inventario Masson, 210 (A) and Bibliothèque Nationale de France (B) Départements des Manuscrits (9).

In the work of Oribasius, the contribution of Vidus consisted in the diversification and improvement of the knot systems and especially of the outstanding graphical presentation that facilitated learning. Finally, the systems for the reduction of dislocations and fractures are initially presented segmentally, and then gradually assembled, indicating where to put the sprockets and pulleys thus making possible the replication of the device for any physician. The images of this last chapter of Guidi`s *Chirurgia* were also made by Francesco Saviati by engravings on copper plates (fig. 4).

After the death of King Francis I (1547), Guido Guidi returned to Italy and settled in Pisa, where he practiced surgery and held public lectures of surgical anatomy through demonstrative dissections of human cadavers (10, 11, 12).

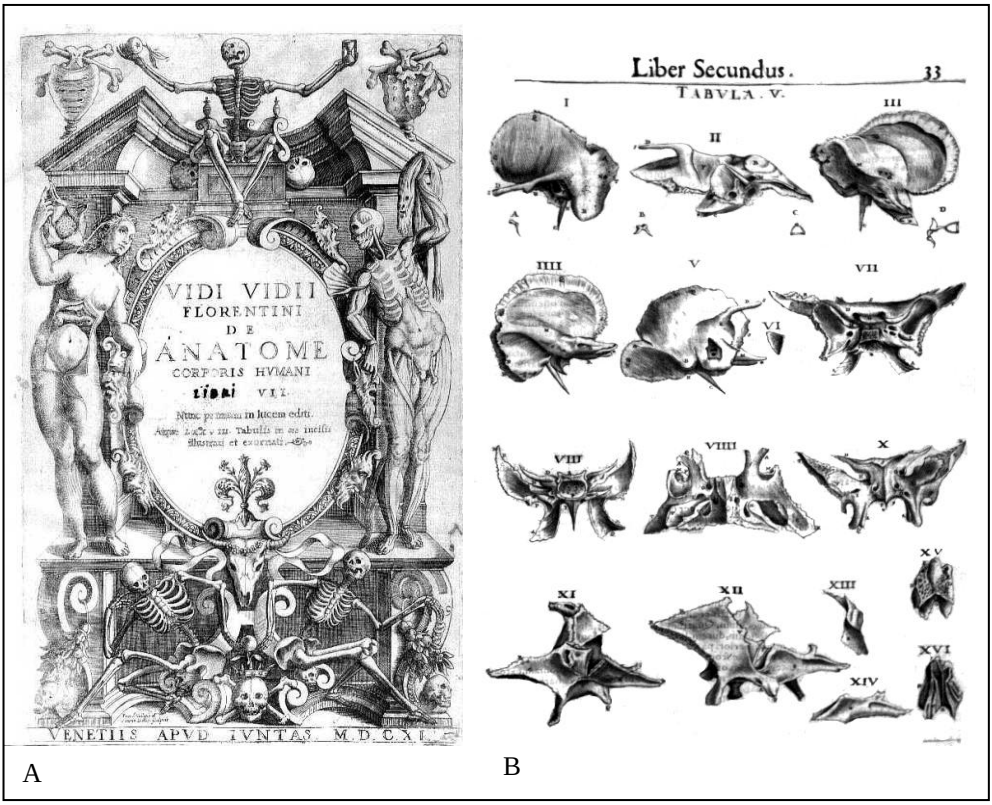

Fig. 5. A. The opening page of the Treaty *De Anatome*; B. Tabula V of Chapter II (Liber Secundus), which presents for the first time, the disarticulated bones of the skull base (7).

This allowed him to accumulate a notable experience in surgery and anatomy that enabled him to add new discoveries to the scientific heritage of the time. In the surgical field he was the first to describe the arterial aneurysms, an original technique of tracheotomy, a procedure of lengthening the foreskin of the penis incurvatus or other sequels of circumcision, cutaneous plasty of trophic limb ulcers, nose plasty, plaster or wax dental implants to improve phonation and he established the axillary lines as landmarks for the thoraco-brachial approach (13, 14).

He named in Italian language *vermiforme*, the ileocecal appendix, discovered by Berengario da Carpi (1460-1530) and described the *ostia* of the hepatic veins openings in the inferior vena cava. In the accompanying drawing it can be observed a rare anatomical variation of five such *ostia*, demonstrating that the study was done by dissection on human corpses.

In the medical field, he was the discoverer of chickenpox. By studying diabetes, he concluded that it was a consequence of a single glandular insufficiency (without specifying the gland). He successfully applied the physiotherapy, using the therapeutic qualities of the baths of Pisa (15).

In the anatomy field, he wrote a remarkable treatise – *De anatome* (fig. 5) – in which he established the conditions of

building a *Theatrum Anatomicum* (5), presented, for the first time, the disarticulated bones of the skull base, described the orbital process of the palatine bone and the pterygoid canal that bears his name – *the vidian canal* (16).

CONCLUSIONS

Although forgotten today, Guido Guidi was a leading figure of the Renaissance medicine, both Italian and French (17, 18, 19). He was the first professor of anatomy and surgery at the Collège de France, and his *Chirurgia*, remained the reference book for teaching surgery in the following two centuries. It is considered the first original surgery book, beautifully illustrated by a famous contemporary Florentine painter. In the field of anatomy Guido Guidi was a prominent personality with important contributions that lasted until today as eponyms in *Nomina Anatomica*.

IN VITRO TESTING OF XANTHAN/LIGNIN HYDROGELS AS CARRIERS FOR CONTROLLED DELIVERY OF BISOPROLOL FUMARATE (Abstract): **Aim**: To develop sustained release matrix tablets based on xanthan as highly water-soluble, cost-effective, nontoxic, easily available, and suitable hydrophilic systems. **Material and methods:** Xanthan and lignin epoxy-modified resin (LER) mixture were crosslinked using epichlorohydrin as crosslinking agent leading to superabsorbent hydrogels with high swelling rate in aqueous mediums. **Results and conclusions**: These hydrogels were tested as carries by the loading/delivery behaviour of bisoprolol fumarate in physiological conditions and based on the obtained results these hydrogels may show interest for application in medical and pharmaceutical areas. The amount of drug loaded in polymer networks was found to be ranging between 14.4 % and 19.2 %. Drug release was retarded and the release mechanism of the active principle was found to depend on matrix composition. **Keywords**: HYDROGELS, XANTHAN, CONTROLLED DELIVERY, BISOPROLOL FUMARATE.

The exopolysaccharide xanthan is produced by the bacterium *Xanthomonas campestris*. Xanthan is a high molecular mass, double stranded anionic polysaccharide which forms solutions that are both highly viscous and very stable under conditions of extreme temperature and salinity. Given these properties and its ability to be manufactured cheaply in large amounts xanthan has gained widespread use as a viscosity controller in a number of different commercial applications ranging from a gelling agent and thickener in food industry (1) and as a rheology controller of the oil-well drilling and for enhancing well-bore recovery in oil industry (2) to a hydrophilic matrix for controlled release of drugs in pharmaceutical industry (3, 4).

Efforts devoted to incorporate lignin preparations into useful polymeric materials have started in 1944, but intensive work has been done in this field, especially in the last twenty years. There are numerous studies on the application of lignin – synthetic polymer blends (5) and very few studies on the application of lignin – synthetic polymer blends in order to obtain new materials (6). Lignin incorporation is expected to

lead to increased thermal stability, hydrophilicity, biocompatibility, biodegradability, antioxidant activity, etc., of different materials (7, 8, 9) and their use in the medical field.

Bisoprolol is a drug belonging to the group of beta blockers, a class of medicines used primarily in cardiovascular diseases. The U.S. Food and Drug Administration approved an application by Duramed Pharmaceutical for Zebeta Oral Tablets (Bisoprolol Fumarate) as a new molecular entity since1992 (10). It is on the World Health Organization's List of Essential Medicines, a list of the most important medications needed in a basic health system (11). Chemically, bisoprolol fumarate is 1-[4-[[2-(1-methylethoxy) ethoxy]-methyl]phenoxy]-3-[(1-methylethyl) amino]-2-propanol(E)-2butenedioate (12).

In this study the crosslinking of a xanthan and lignin mixture in the presence of the epichlorhydrine, leading to superabsorbent hydrogels with high swelling rate in aqueous mediums is discussed. Bisoprolol fumarate was loaded in these matrices followed by drug release in order to obtain information regarding their application as.

MATERIAL AND METHODS

Materials. The food grade xanthan gum (X) used in this study was purchased from CP Kelco – France, and used without any further purification. Epoxy modified ammonium lignosulfonate (LER) used for the study was obtained by reacting ammonium lignosulfonate with epichlorohydrine in 1/10 ratio, in the presence of a 35-40 wt% NaOH solution at 75 ^{o}C, for 5 hours (13). Bisoprolol fumarate (BF) – 100.07 % pure reference substance was purchased from Unichem Laboratories LTD, India.

Hydrogels preparation. Xanthan/ modified lignin hydrogels were prepared in various mixing ratios of the two polymers in the presence of NaOH and epichlorohydrine (EPCl) at 80°C. The hydrogels have been washed repeatedly with twice distilled water until neither lignin nor epichlorohydrine were detected in the washing waters by UV spectroscopy.

Swelling degree of xanthan/LER hydrogels. The swelling behavior of hydrogels was gravimetrically determined. The swelling degree was calculated using the following equation:

$$\%SD = [(m_t - m_0) / m_0] \cdot 100 \qquad (1)$$

where m_t is the mass of the swollen hydrogel at time t and

m_0 is the mass of dry hydrogel at time 0. The experiment was carried out in twice distilled water at room temperature.

Drug loading. The applicability of xanthan/lignin (X/LER) hydrogels as carriers for controlled delivery of active principles in pharmaceutical and medical fields was tested by using bisoprolol fumarate, a synthetic beta1-selective (cardioselective) adrenoceptor blocking agent. The incorporation of bisoprolol fumarate in the polymeric matrix was performed by immersing the sample in 50 mL twice distilled water solution with a drug concentration of 0.05 % at room temperature for three days. The bioactive compounds were then dried in the vacuum oven at a temperature of 60 ^{o}C for 24 h. Drug loading degree was estimated using an UV-Vis spectrometer (Cary 60 Spectrophotometer). The amount of active drug loaded in hydrogel matrices was determined according to the standard curve of bisoprolol fumarate absorbance in twice distilled water. Thus, the estimation of drug content was performed based on calibration curve of maximum absorption of bisoprolol fumarate, depending on drug concentration,

on UV-Vis range.

In vitro drug release. The *in vitro* dissolution profiles of the designed formulations were carried out using an Agilent 708–DS Dissolution Apparatus connected at UV-Vis Cary 60 Spectrophotometer. Each hydrogel specimen, with a mass of 0.018 g, was placed in basket support and suspended in 100 mL phosphate buffer pH. 7.4 (14, 15). Drug release tests were performed at 37°C and the stirring speed was 100 rpm.

RESULTS AND DISCUSSIONS

Swelling study

The water sorption kinetic curves of X/LER hydrogels (fig. 1) showed that water uptake is very fast in the first 5-6 minutes, after that all samples reaching equilibrium. The equilibrium swelling degree (the plateau of the curves) is considered the maximum swelling degree.

The slopes of the curves, which represent the swelling rate, were determined for the first 10 minutes by using the following equation:

$$dq/dt=Kq^n \qquad (2)$$

Both, the maximum swelling degree and the swelling rate are decreasing with the increase in lignin content (fig. 2, 3).

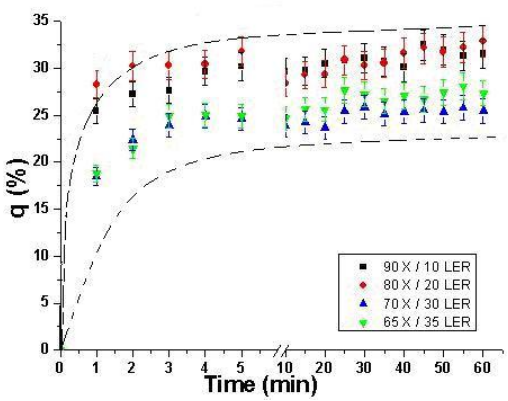

Fig. 1. Time variation of swelling degree for X/LER hydrogels

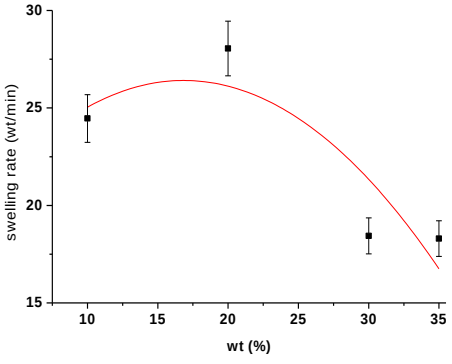

Fig. 2. The variation of the maximum swelling degree with lignin content

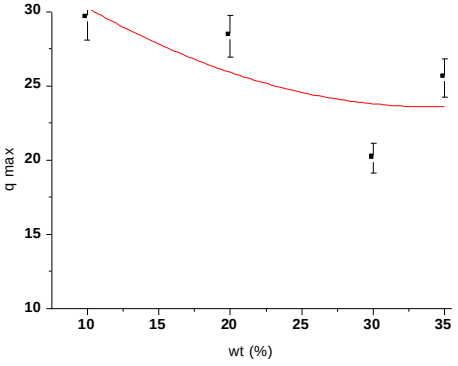

Fig. 3. The variation of the swelling rate with lignin content

In vitro drug load / release studies

The drug loading process of xanthan/lignin polymeric networks were found to be influenced by the composition of hydrogels (tab. I). An increase in the networks loading capacity with the decrease in xanthan content was found, with a maximum load capacity of 19.2 % recorded for 65 X/35 LER hydrogel.

Drug delivery profiles showed a fast release of approximately 60% (fig. 4) of the total drug content loaded in the polymeric network within the first 10 minutes followed by controlled drug release for 72 hrs. In the selected interval for the experiment there was no plateau, the release continuing after this time range. The experimental data related to the release of bisoprolol fumarate were processed to determine the kinetic parameters by the Korsmeyer - Peppas model (3), according to the equation:

$$Mt/M_0 = K \times t^n$$

where, M_t is the mass of the released drug at predetermined time (t), M_0 is the mass of the released drug at the end of the process, K is the rate constant and n is the release exponent used for the estimation of release mechanism.

TABLE I
Drug loading degree of hydrogels

Sample code	Drug loading degree determined by UV-Vis (%)
90X/10LER	14.4
80X/20LER	14.8
70X/30LER	16.4
65X/35LER	19.2

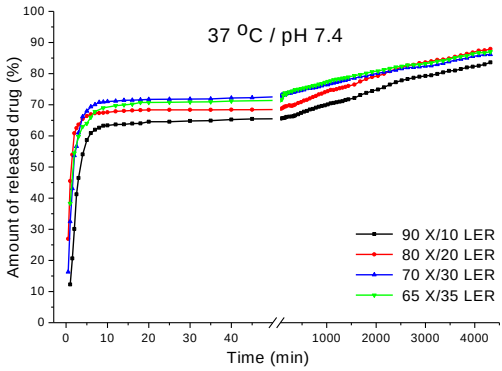

Fig. 4. Drug release profiles of BF from X/LER hydrogels with different composition

TABLE II
Drug release kinetic characteristics

Sample code	N	R^2_n	K, min $^{-n}$	R^2_k
90X/10LER	0.80	0.993	0.13	0.998
80X/20LER	0.42	0.999	0.45	0.999
70X/30LER	0.72	0.999	0.32	0.999
65X/35LER	0.41	0.97	0.39	0.97

n = the release exponent, R^2 = correlation factor, K = the rate constant

Table II shows that drug release kinetics of polymeric networks 90X/10LER and 70X/30LER respects an order of 0.5 - 1, indicating a non-Fickian diffusion behavior meaning that the diffusion rate is higher than the rate of relaxation in the polymer chains. Samples 80X/20LER and 65X/35LER present a drug release kinetics of the order

of 0.5 which indicates a Fickian diffusion behaviour where the drug release takes place by diffusion at a rate equal to the rate of relaxation of the polymer chains.

CONCLUSION

In this study the ability of xanthan with epoxy modified lignins in the presence of epichlorhydrine hydrogels to release *in vitro* bisoprolol fumarate in a controlled retarded manner. The ability of hydrogels to swell in water depends of their composition. The high swelling degree indicates their superabsorbent properties. The amount of drug loaded in polymer networks ranged from 14.4 % to 19.2 %, the maximum value being obtained for the hydrogels with the highest amount of lignin (LER). The release of bisoprolol fumarate from hydrogels was influenced by hydrogel composition. The X/LER-based hydrogels loaded with bisoprolol fumarate may be of interest for application in medical and pharmaceutical areas.

NEWS

THE EVALUATION OF THE ANTIMICROBIAL SUSCEPTIBILITY AND MICROBIAL PROFILE OF SUBGINGIVAL BIOFILMS IN INDIVIDUALS WITH AGGRESSIVE PERIODONTITIS

The study realized by a group of Brazilian researchers aimed to evaluate the antimicrobial susceptibility and composition of subgingival biofilms in case of generalized aggressive periodontitis patients treated using mechanical/antimicrobial therapies (chlorhexidine, amoxicillin and metronidazole). Generalized aggressive periodontitis patients allocated to the placebo (C, n = 15) or test group (T, n = 16) received full-mouth disinfection with chlorhexidine, scaling and root planning, and systemic amoxicillin (500 mg)/ metronidazole (250 mg) or placebos. Subgingival plaque samples were obtained at baseline, 3, 6, 9 and 12 months post-therapy from 3-4 periodontal pockets, and the samples were pooled and cultivated under anaerobic conditions. The minimum inhibitory concentrations of amoxicillin, metronidazole and chlorhexidine were assessed using the microdilution method. Bacterial species present in the cultivated biofilm were identified by checkerboard DNA-DNA hybridization. At baseline, no differences in the minimum inhibitory concentrations between groups were observed for the 3 antimicrobials. In the T group, significant increases in the minimum inhibitory concentrations of chlorhexidine ($p < 0.05$) and amoxicillin ($p < 0.01$) were detected during the first 3 months; however, the minimum inhibitory concentrations of metronidazole decreased at 12 months ($p < 0.05$). For several species, the minimum inhibitory concentrations significantly changed over time in both groups, i.e., Streptococci the minimum inhibitory concentrations tended to increase, while for several periodontal pathogens, the minimum inhibitory concentrations diminished. A transitory increase in the minimum inhibitory concentrations of the subgingival biofilm to amoxicillin and chlorhexidine was observed in generalized aggressive periodontitis patients treated using enhanced mechanical therapy with topical chlorhexidine and systemic amoxicillin / metronidazole. Both protocols presented limited effects on the cultivable subgingival microbiota (Lourenço TG, Heller D, do Souto RM, Silva-Senem MX, Varela VM, Torres MC, Feres-Filho EJ, Colombo AP. Long-term evaluation of the antimicrobial susceptibility and microbial profile of subgingival biofilms in individuals with aggressive periodontitis. *Braz J Microbiol.* 2015 1;46 (2) :493-500).

CANCER RESEARCH INVESTMENT: "TOP-DOWN" VERSUS BIBLIOMETRIC APPROACH (Abstract): Cancer is a complex chronic disease with a real burden that goes beyond the individuals and their families to healthcare budgets and society. At the global level there are still many gaps in the knowledge on cancer research funding and activity. **The aim** of this paper is to present two approaches that can be used for the collection of data on cancer research investment. **Material and methods**: A scientific literature search was performed within the three databases (PubMed, Science Direct and OVID MEDICAL), using different combinations of some key words**. Results:** We identified 7 papers that used the "top-down" method and 4 that used the bibliometric approach for data collection on cancer research investment. Using the first method, usually the cancer research funding from public domain were cached, while using the second the overall expenditure (including indirect funding) could be estimated. **Conclusions**: The best approach for the collection of cancer research funding information is a combination of bibliometric with "top-down"/ "bottom-up" methods, which allows the assessment of oncological research activity and impact, but also the evaluation of the amount of money invested on cancer research from different perspectives. **Keywords**: CANCER, RESEARCH, FUNDING, BIBLIOMETRIC APPROACH, TOP-DOWN APPROACH.

Cancer is a complex chronic disease, which change forever the life of an individual affected by it. Also, cancer is one of the leading causes of death worldwide (1). The real burden of this disease goes beyond the individuals and their families to healthcare budgets and society.

With more than 14 billion euro global expenditure on oncological research (2) and an upward trend in the burden of this disease worldwide (3), cancer is one of the major global policy issues. Many financial resources were invested to study cancer initiation, etiology, diagnosis, prognosis, prevention, and treatment (4) and different methods were used to assess these expenses. But these financial resources are limited and all these methods have advantages and disadvantages. So, the correct allocation of the funds is very important. In order to help this

allocation of funds according to the burden of cancer in a specific population/ society, there is a need to obtain information on oncological research investment in different countries, regions, continents or worldwide (Europe, United States of America – USA, Canada, Australia and Asia). There are some examples of studies in the literature which provide such an analysis (4, 5, 7, 19, 20), but at the global level there are still many gaps in the knowledge on cancer research funding and activity.

To map the funding priorities in cancer research in order to correspond to the actual population/society needs is a major policy issue, but the collection of this data is usually hard (27).

The aim of this paper is to present two approaches that can be used for the collection of data on cancer research investment.

MATERIAL AND METHODS

We performed a scientific literature search within the three databases (PubMed, Science Direct and OVID MEDICAL), using different combinations of some key words: "cancer (or neoplasm or malignancy) AND research AND funding (or expenses or expenditure or costs)". Also, another search was performed using the following combinations: "cancer research funding in Europe"; "cancer research funding in Asia"; "cancer research funding in Australia"; "cancer research funding in Canada" and "cancer research funding in USA".

The total number of paper (including duplicates) obtained in PubMed was 20,957, in Science Direct was 87,560, and in OVID MEDICAL [Ovid MEDLINE (R) 1946 to February Week 4, 2015] was 5,617. After duplicate removal, the titles and abstracts of the remaining articles were evaluated against the following inclusion criteria: (1) published between 2005 and 2014; (2) published in English; (3) full text; (4) humans as subjects; (5) worldwide. A secondary literature search was performed using the references cited in the selected papers. A total of 22 articles were identified, for which the full-text version were obtained.

From these papers 7 used the "top-down" method and 4 used the bibliometric approach for data collection.

RESULTS

The scientific papers reporting on oncological research funding were conducted in the following geographical regions: Europe (2, 5, 6, 7, 8, 9, 10, 11, 12, 13), USA (4, 14, 15, 16), Australia (17, 18, 19), Canada (20, 21, 22) and Asia (23, 24).

The methods used to collect data on cancer research expenditure for the studies identified in the literature were: letters sent to the relevant Institutions/ Organizations (2, 5, 6, 7, 11, 16, 17, 18, 19) or to leading cancer researchers (2, 18, 19), interrogation of the most relevant databases regarding the data on cancer research papers (the outputs of cancer activity) (2, 5, 16, 24), information from institutional websites (where available) (2, 5, 6, 7, 11, 17, 18, 19) or interrogation of common databases regarding cancer research funding (2, 4, 11) (tab. I).

From all these methods the most used was the "top-down" approach (25, 26). This method involves a direct survey that collects data from organizations that fund cancer-related research or from organizations that administer cancer-related projects and programs (universities and hospitals). First step is the identification of these organizations. Then letters is sent to each institution and specific data related to can-

cer research expenditure are required (such as the name of funding organization, the name of the project, the name of the chief investigator, type of funding organizations, collaborators, source of funding, the amount of money spent by Common Scientific Outline – CSO – categories, and by cancer site) (7, 19). Besides, the researchers involved in the assessment of oncological research investments evaluate the amount of money spent by political group, by countries/territories, and by Gross Domestic Product (GDP)/ per capita. Where the information is incomplete or it is not provided, the chief investigators are contacted and asked for this data. Also, the websites are checked were available. Follow up letters are sent to the organizations which do not respond to the first request. Many attempts (letters, emails, and phone calls) are used to contact these institutions. The information has to be cross checked. If there are data provided in other currencies than the official currency used in the survey, they are converted within maximum two days of receipt of the information. Other type of currency conversion could be the usage of an average conversion rate over the calendar year. This approach avoids the involvement of variations in currency conversion rates as a confounder (4). A final verification letter could be sent to all organizations providing them with the figures for their institution as well as for the other institutions in the country and ask them for updates (7, 19). The response rate for "top-down" method is high (62-96%) compared with "bottom-up" approach, which means to directly contact the leading cancer researchers (27-42%) (2, 17, 19).

TABLE I

Methods used in the literature to collect data on cancer research investment

No.	Methods used in different studies to collect data on cancer research investment [authors / year of publication (reference)]				
	"Top-down" approach	**Bibliometric approach**	**"Bottom-up" approach**	**Web sites interrogation**	**Common databases interrogation**
1	Cancer Australia / 2014 (17)	Eckhouse S et al. / 2008 (2)	Eckhouse S et al. / 2008 (2)	Cancer Australia / 2014 (17)	Eckhouse S et al. / 2008 (2)
2	Eckhouse S et al. / 2008 (2)	Eckhouse S et al. / 2007 (5)	Shiraze N et al. / 2011 (18)	Eckhouse S et al. / 2008 (2)	International Cancer Research Partnership / 2012 (4)
3	Eckhouse S et al. / 2007 (5)	Gillum LA et al. / 2011 (16)	Shiraze N et al. / 2011 (19)	Eckhouse S et al. / 2007 (5)	Kanavos P / 2010 (11)
4	Eckhouse S, Sullivan R / 2006 (6)	Hong W, Dong E / 2014 (24)		Eckhouse S, Sullivan R / 2006 (6)	
5	Eckhouse S et al. / 2005 (7)			Eckhouse S et al. / 2005 (7)	
6	Gillum LA et al. / 2011 (16)			Shiraze N et al. / 2011 (18)	
7	Kanavos P / 2010 (11)			Shiraze N et al. / 2011 (19)	
8	Shiraze N et al. / 2011 (18)				
9	Shiraze N et al. / 2011 (19)				

Using the "top-down" approach, Eckhouse et al. showed that in 2004 the non-commercial funding organizations spent €1.97 billion (on direct funding of cancer research) in Europe and €5.15 billion in USA. Besides, there were €1.36 billion in Europe and €0.10 billion in USA from national healthcare systems and universities ("hidden" expenses or indirect funding). Also, there were €3.09 billion from Pharmaceutical Industry (direct spending) worldwide contributing to public domain (not all companies). So, in 2004 a total of €11.67 billion were invested from public domain on cancer research (2, 5).

The bibliometric method for the assessment of cancer research investment was taken into account for the evaluation of direct (2, 5, 16, 24) or indirect costs (2, 5).

There are many ways of using the bibliometric approach. First, it could be evaluated the total number of scientific articles on cancer, over a specific period. The relevant databases are searched (ISI Thomson Web of Science, PubMed, Google scholar etc.) using specific filters / queries (2, 5, 24, 27). There is the possibility to select the topic, the language, the type of documents, the timespan and other settings (*eg*. Citation Indexes in the case of ISI Thomson Web of Science). There are Boolean operators, parentheses, field tags, and query sets available to help the researcher with the creation of his own query. When the final results were obtained, an Excel database could be used to store the bibliometrical details of each scientific article. The number of papers related to a country / region / organization could be evaluated using two methods of counting: the integer counting (which means that a paper is counted as unity for each country / institution appeared among the addresses) or fractional counting (which means that the researcher have to divided the number of addresses for a particular country / institution by the total number of addresses identified in the article) (28). The analysis could provide data on the type of research (basic/ clinical), the type of funding organization, the type of collaboration (national/ international) and regarding the values by CSO or by cancer site. Second, the quality of cancer research outputs could be evaluated using the impact factor of the journals which published the scientific paper (24) (the scientific value of the journal in which were published the outputs) or the actual citation impact, defined as the number of citations received by a specific article in the next 5 years after its publication (28) (the scientific value of the papers itself). Also, the potential citation impact could be used in this respect. The last indicator is calculated as the number of citations expected to be received by an individual paper, considering that is cited with the average frequency for papers of that journal in that year (28).

Some authors evaluated the number of research papers on cancer over a specific period (usually a 10-year period) in a specific country / region (2, 5, 24), others provided a deeper analysis and calculated the impact of the outputs on cancer research or estimated the amount of money spent on oncological research (using the number of research outputs identified for a specific country / region / institution and the mean cost per paper (2, 5, 27).

Using the bibliometric approach was shown that the Global Public Sector cancer research expenditure was around €11.03 billion, from which: USA = €5.27 billion, Europe = €3.33 billion, Japan = €1.00 billion, Canada = €0.27 billion, Australia =

€0.16 billion and the Rest of the World = €0.98 billion. The major funder for oncological research were the Government (€4,712 million), followed by Charity (€456 million) and healthcare systems and universities (€109 million) in the USA, whilst the universities and healthcare systems (€1,364 million), followed by Government (€992 million), and, Charity (€872 million) were the relevant funders in EU (5). Although, the USA invested a higher amount of money in cancer research compared to Europe (5), these regions were comparable when analyzed their overall oncological research productivity as a volume of publications (2).

In China, the scientific papers resulting from breast cancer research followed an upward trend over the period of 2004-2013. Although, the number of articles from China rose from 267 in 2004 to 3,414 in 2013, was still far behind the USA (with more than 7,000 papers), but well in advance compared with other countries such as Japan (1,030), England (1,157) or Germany (1,196) (24).

DISCUSSION

The bibliometric method is a relatively new tool used for the assessment of cancer research funding priorities (2, 27, 28).

The expenditure evaluated using the bibliometric approach was 41% greater in Europe than the amount of money found using the top-down method (directly reported funds) combined with other methods, except the bibliometric one, and 2% greater in the USA (5). Over a 10-year period, from 1994 to 2003, when the assessment was done in absolute terms (% of total number of publications), European cancer research activity was dominated by Germany (9.6%), UK (9.1%), Italy (7.3%), and France (6.79%), followed by Netherlands (3.6%) and Sweden (2.5%), but when the analysis taken into consideration the number of papers / billion euro GDP, Sweden (2.2), Greece and Netherlands (2.1 each) had the greatest outputs (2, 5).

The difference between data collected using the bibliometric approach (national estimation) and "top-down" methods (directly reported investments) in Europe resulted from the funds added by the universities and healthcare services (money spent for infrastructure), so called indirect costs (5).

The "top-down" approach is a widely used method for the data collection on cancer research funding, with the advantage of providing directly reported information, usually with high accuracy. Generally, this method catches data on public domain. But, there are some aspects that could be considered as disadvantages. First, in some cases there is a need for many follow-up letters, phones, and emails to get the expected percentage of answers. So, sometimes the rate response could be too low. Second, the rate response from private organizations could be even lower.

The number of articles published is considered as a good measure of oncological research efforts. Vanderelst D et al. showed that the volume of publications represents a valid estimate of the magnitude of research funding (27). So, the bibliometric approach is a reliable way to collect information on cancer research investment. Even more, some authors found that the number of published articles was correlated with the burden of a disease on the population / society (Swingler G et al., 2003, cited by Vanderelst D et al.) (27). Cancer research scientific papers are one of the major outputs of investment and an

objective surrogate of the global cancer research activity and impact (2, 28). Besides, the scientific productivity in specific areas of research (including cancer) could stimulate further interest from researchers and the funding organizations and could support some the targeted investments (16). This method is useful when there is a short period of time available for the estimation of oncological research expenditure. However, the analysis of cancer research investment in Far East (especially China and India), but also in Latin America and Russia, is difficult because the names of many authors are the same and an important percent of these papers are published in other languages and national journals that do not appear in the most relevant databases such as ISI Thomson Web of Science, PubMed, Google Scholar and so on, which are English-databases (2). Also, the bibliometric approach provides estimated values.

CONCLUSIONS

1. There are many different methods that could be taken into account for data collection on oncological research investment, with advantages, but also with disadvantages.

2. The "top-down" approach is a widely used method for the assessment of cancer research expenses, especially from public domain, which provides directly reported data, but sometimes at a lower response rate.

3. The bibliometric approach is a relatively new tool for the evaluation of cancer research funding, but also on the impact of this activity. This method helps the setting of cancer research funding priorities and the appropriate financial resources allocation, according to the actual population/society needs.

4. The best approach for the collection of cancer research funding information is a combination of bibliometric with "top-down" / "bottom-up" methods, which allows the assessment of oncological research productivity and scientific impact, but also the evaluation of the amount of money invested on cancer research from different perspectives.

STUDY ON HEALTH PROFESSIONALS' PERCEPTION OF QUALITY OF HEALTHCARE PROVIDED TO PATIENTS (Abstract). The quality of the health care system is an essential condition for in improving the quality of health services and satisfying both the patients and healthcare professionals. **Research objectives**: To identify the characteristics of medical profession, the factors of professional satisfaction or dissatisfaction and health care team-related factors that influence the quality of care. **Material and methods**: Qualitative study using a SurveyMonkey online questionnaire consisting of 14 open-ended questions. The respondents were 1013 health professionals in university and non-university hospitals with various unit profiles. **Results**: According to healthcare professionals, medical profession is defined by: humanism and personal sacrifice (33.37%) and also high professional competence (33.07%). Satisfaction factors are: patient health (40.57%), high social status (36.33) and saved lives (33.07%). Dissatisfaction may be due to: low salary (39.98%), disorganization (38.10%) and lack of procedures (33.96%). Performance may decrease as a result of: stressful working conditions, lack of adequate medical supplies, lack of recognition at work, routine, and strained relations with superiors. **Conclusions**: The study shows the need for correlating the medical education system and health systems, and for an integrated analysis of both systems by determining the required skills and modeling the medical team behavior in accordance with the performance variables which take into account satisfaction among both patients and health care professionals. **Keywords:** PROFESSIONAL, PERCEPTION, QUALITY, HEALTHCARE.

Every healthcare professional knows that the needs of patients vary from individual to individual. Also, patient safety and quality of care make a difference for patients and their families (1). Thus, on the one hand, healthcare professionals use their knowledge and skills, and on the other hand their experience, intuition and creativity to meet these needs. Health professionals must know that the quality of care is assessed by outcome measurement (2). Implementation of a monitoring system is essential for a successful quality improvement program. Even with limited resources systematic methods can be used to constantly monitor the quality of care. Quantifying the effect that nurses and nursing interventions have on the quality of care processes, and on patient outcomes, has become increasingly important to support

evidence-based staffing plans, understand the impact of nursing shortages and optimize care outcomes" (3, 4).

Monitoring the quality of care is the regular collection and analysis of a set of quality indicators, and is frequently directed toward the measurement and analysis of processes. This process allows health care providers to assess whether the program or its performance targets are met (5, 6).

Aim of the study: To improve health system performance in accordance with the elements identified by assessing the degree of satisfaction of both patients and healthcare professionals.

Research objectives: To identify the significant characteristics of medical profession, factors of job satisfaction or dissatisfaction, and health care team-related factors that influence the quality of care.

MATERIAL AND METHODS

The qualitative survey research was conducted by using SurveyMonkey online questionnaire consisting of 14 open-ended questions. It has been applied to a number of 1013 health professionals in hospitals from 6 university centers in Romania: Iasi, Bucharest, Cluj-Napoca, Târgu Mures, Timiş oara, Craiova and non-university hospitals in 9 cities. The profile of these hospitals was varied: obstetrics and gynecology, neurology and psychiatry, lung disease, pediatrics; medical rehabilitation; infectious diseases or general hospitals (emergency hospitals). Their inclusion in the study was possible after obtaining the agreement of hospital managers, doctors or other healthcare professionals.

The questionnaires included open-ended questions aimed at identifying the degree of satisfaction of responders. Thus, 10 important issues were addressed: delivered health care, humanism reflected in treatment, absence of pain, prompt response to all requests and needs. Respondents' opinions on dissatisfaction factors that have bothered them most were expressed about the 30 possible factors that contribute to a disturbing degree of dissatisfaction during hospitalization. The non-response rate/refusal rate was 0.1%, not influencing significantly the quality of results. Data were processed according to the studied qualitative variables for a statistical significance of the results with 95% confidence interval.

RESULTS

Description of study population

The analysis of study group composition showed that respondents were people with higher education. According to the variable "age" the group showed a relatively homogeneous distribution, consisting of 149 persons under 30 years (14.7%), 207 persons aged 30-35 years (20.4%), 218 aged 35-45 years (21.5%), 287 people aged 45-50 years (28.3%) and 152 people aged over 50 years (15%). According to "length of service" 37.8% had more than 20 years professional experience; 25% of 10-20 years; 22.2% between 5-10 years, and a relatively small percentage (14.7%) had worked in the healthcare system less than 5 years.

The results obtained after processing the responses to the questions reveal the following:

1. "What are the three main characteristic features defining the medical profession?" Responses revealed that an equal number of physicians, 338 (33.4%) believe that sacrifice and humanity, respectively are defining characteristics of their profession. Other responses were: competence (335/33.1%), dedication and thorough theoretical knowledge (0.1% each).

Dedication and knowledge were for 170 physicians each (16.8%) the basic characteristic features of medical profession, while 16.7% each opted for talent and perfection. Similar percentages were obtained for responsibility and self-control. Respect and rigor were preferred by 170 respondents each (16.8%) and experience and intelligence by 169 respondents each (16.7%). Work speed was selected by 168 respondents (16.6%) as an essential condition that must be met in order to practice medicine. In conclusion, according to our respondents he 3 main characteristic features of medical profession are: **humanism and sacrifice** (33.37% each), and **competence** (33.07%).

2. "What are the three factors of satisfaction with medical profession?" The results show that: the highest percentage of responders (40.57%) considered patient health as the most important factor impacting professional satisfaction; other responses were: saving lives (33.1%); social status (265 respondents (26.2%); freedom in decision making (1respondent/0.1%). Patient gratitude is considered by 332 physicians (32.8%), as the main factor contributing to professional fulfillment and satisfaction, while the same is true for respect in the community according to 289 physicians (28.5%). 19.9% of respondents find professional satisfaction in their status, and 9.9% believe that nothing can please them more professionally than one recovered patient. Synthesizing the answers it can be concluded that there are 3 primordial factors of professional satisfaction: **patient health** (40.57%), high social status (36.33) and **saved lives** (33.07%).

3. "What are the three main factors of dissatisfaction in the medical profession?" The results showed that: for the highest percentage (40.0%) of respondents the main reason for professional dissatisfaction is related to low salary, while 34.6% attribute it to physical wear and 25.2% to lack of respect. Another factor responsible for the lack of satisfaction is the absence of procedures, according to a number of 344 physicians (34.0%). A percentage of 26.7 believe that lack of discipline leads to professional dissatisfaction, and 21.4% attribute it to lack of culture. "Insufficient funds to equip the hospital" is the reason for professional dissatisfaction for a number of 98 physicians (9.7%). One physician (0.1%) considers denigration as the key factor of professional failure to which the lack of professional recognition and community appreciation is added. The lack of organization in the health system is a factor that causes professional dissatisfaction in the opinion of a number of 386 physicians (38.1%). Interpretable legislation is another plausible cause of achieving the level of professional dissatisfaction for 252 physicians (24.9%). After analyzing all responses it can be concluded that the main factors of professional dissatisfaction are: **low salary** (39.98%), **lack of organization** (38.10%) and the **absence of procedures** (33.96%).

4. "Sorting by relevance the factors related to patient care". The analysis of a first group of factors (group 1) aimed to determine the importance of: equipment, medical resources, prompt response to patient requests or needs, patience, and kindness. The variable "equipment" was ranked second among the factors related to patient care by 71.08% of responders, third by 6.52%, fourth by 6.91%, sixth by 0.10%, seventh by 8.39, and eighth by 7.01%. "Medical resources" (medical supplies) were ranked second by 0.10% of the respondents and fourth by 8.49%, while the

highest percentage of responders (61.8%) ranked it ninth. The variable "patience" was ranked: first by 6.42%, second by 6.92%, third by 8.39%, while most respondents (66.54%) ranked it ninth. According to 0.10% of the respondents "kindness" is the third most important factor related to patient care, being ranked sixth by 8.39%, seventh by 7.01%, eighth by 6.91% and tenth by 77.59% of the respondents. In the second group of factors related to patient care (group 2) the following variables were analyzed: competence, hospital environment, empathy, counseling time allocated to each patient, nurse dedication, responsiveness and patient attitude. The synthesis of results showed the following ranking in order of importance: "competence" (71.27% of respondents), "equipment" (71.08%), "counseling time allocated to each patient (51.53%), "responsiveness and patient attitude" (55.97%), "nurse dedication" (44.82%), "hospital environment" (51.04%), "empathy" (51.04%), "prompt response to the patient requests and needs" (51.04%), "patience" (66.54%), "kindness"(77.59%), "medical resources" (61.8%). According to the cumulative summary of respondents' opinion on issues that can diminish work performance at work, these were in order of importance the stressful working conditions, lack of adequate medical resources, lack of recognition, routine and strained relations with superiors (tab. I).

DISCUSSION

The responses of the study subjects related to ranking the factors influencing the quality of patient care revealed that a significant percentage of respondents (70%) ranked the variables "competence" and "equipment" first and second, and over half of respondents considered the variables "counseling time allocated to each patient" and "responsiveness and patient attitude. A significant proportion of respondents (60%) believe that the following variables influence the quality of care to a lesser extent: "patience", "kindness" and "medical resources (medical supplies)". As to respondents' opinion on issues that may negatively influence job performance, over 50% of respondents ranked first the variable "stressful working conditions" and about 40% also considered important the variable "lack of appropriate medical resources ", ranking it second (out of nine). In a performance health system the most important variables are "competence" and "equipment", variables depending on the education system and the level of funding (7). A highly trained staff cannot compensate for lack of funding and modern equipment, but the latter cannot replace professional competence (8).

CONCLUSIONS

1. Our research demonstrates the need for correlating the education and health systems in view of establishing the knowledge and skills required for modeling the medical team behavior in accordance with patient satisfaction.

2. An organizational culture that creates an environment based on respect, kindness, courtesy, recognition for a job well done has to be developed.

3. Based on the obtained results the introduction into educational curricula in Romania of research directions aimed at developing behavioral and ethical practices specific to health professional-patient relationship, knowledge and respect of patient rights, and increased resistance to demanding work is recommended.

NEWS

EU RECOMMENDS APPROVAL OF *GARDASIL 9* VACCINE

The European Medicines Agency (EMA) has recommended approval for the new vaccine *Gardasil 9*, which provide protection against the infection caused by nine serotypes of *Human Papillomavirus* (HPV) – 6, 11, 16 and 18 (from the earlier version of the vaccine), and other five - 31, 33, 45, 52, 58, which are new. The latter HPV types are responsible for around 1 in 5 cases of cervical cancer. EMA highlights on the implications of the infections with HPV: about 100% of cervical cancers, 90% of anal cancers, 70% of vaginal cancers, and 15% of vulvar cancers; also, certain types of HPV are linked to mouth and throat malignancies. The indications of this new vaccine include: 1. girls and young women, between 9 and 26 years (it offer protection for cervical, vulvar, vaginal and anal cancers caused by HPV types 16, 18, 31, 33, 45, 52, 58; genital warts produced by HPV types 6 and 11; and other dysplastic lesions of the cervix, vulva, vagina and anus, caused by these all HPV serotypes). 2. boys, between 9 and 15 years (to prevent anal cancer caused by oncogenic HPV types 16, 18, 31, 33, 45, 52, 58; genital warts caused by the benign HPV types 6 and 11; and anal intraepithelial neoplasia). The EMA recommendation is based primarily on four studies that analysed the efficacy of *Gardasil 9* for the protection against the infections caused by HPV types 31, 33, 45, 52 and 58, but also assessed the protection against the HPV types 6, 11, 16, 18, compared with the first variant of the vaccine, *Gardasil* (which was authorized for use in the European Union since 2006). One of these studies was conducted on 14,000 young women, between 16 and 26 years, who were negative for vaccine HPV types at the beginning of the study. The results showed that *Gardasil 9* was 97% effective in preventing cervical, vulvar and vaginal cancers caused by the additional HPV types (31, 33, 45, 52 and 58) and had similar efficacy as *Gardasil* against 6, 11, 16 and 18 (on the basis of similar antibody responses). The EMA notes that the safety of *Gardasil 9* was evaluated in more than 23,000 people included in seven clinical trials. The most frequent side effects were injection site pain, swelling, redness and headaches. *Gardasil 9* is already approved by US Food and Drug Administration for marketing in the USA (since the end of the last year) (Nelson R. EU Recommends Approval of Gardasil 9 Vaccine. *Medscape*. March 27, 2015).

QUALITY OF LIFE OF AMBLYOPIC CHILDREN AND THEIR PARENTS (Abstract). **Aim:** To highlight the changes in the quality of life in patients with anisometric, refractive, strabic and mixed amblyopia and to assess the psychosocial implication for their family. **Material and methods:** Prospective observational transversal study of 44 ambulatory patients (88 eyes) treated in the Ophthalmology Clinic of Iaşi "Sf. Spiridon" Hospital and Iaşi Stereopsis Ophthalmology Clinic. Clinical parameters: visual acuity, objective refraction (autorefractometry), optical correction type, stage of binocular vision, ocular motility, strabic deviation. The patients or their attendants accepted to fill out a questionnaire comprising 46 items pertaining to 9 domains to assess patient (or parents) adherence to treatment and issues related to quality of life. **Results:** Mean age of study patients was 8.19±2.92 years (range 4-16 years) and age at first diagnosis was: 3.90±2.15 years. Moderate and severe amblyopia in the right eye was present in 47.72% of cases and in the left eye in 43.18%. Right eye uncorrected visual acuity was 0.45±0.31 and corrected 0.63±0.31 ($p<0.0001$). Left eye uncorrected visual acuity was 0.49±0.33 and corrected was 0.69±0.32 ($p<0.0001$). No statistically significant difference between the right and left eye were found. A 46-item questionnaire focused on child health, visual acuity, binocular vision, time to occlusion or penalization, child emotions/activity, family and society integration was used. **Conclusions:** The first presentation to the ophthalmologist was at age 3.9091±2.1597 years (range 3 months-7 years). Health promotion and education is important to determine parents to seek help from an ophthalmologist not later than age 3. The main symptoms that led the parents to seek eye care were: strabic deviation – 45.45%, difficulty seeing the blackboard – 11.36%, and difficulty in seeing closer – 20.45%. Quality life questionnaires detect life or school problems of children with amblyopia and educate parents. In 15,91% of parents they did not knew that before treatment the child had poor school results. This study represents the first step in Romanian ophthalmologists concern for socio-professional integration of children with amblyopia, because as we know some jobs require healthy eyes and for those who do not receive appropriate treatment their dream will be denied. **Keywords:** AMBLYOPIA, QUESTIONNAIRE, QUALITY OF LIFE.

The word amblyopia is derived from the Greek amblyos which means "blunt vision" (1) and the first description was made by Hippocrates in 400 BC. Amblyopia is an important condition that can affect up to 5% of the general population (2,3). Many people with amblyopia, especially those who only have a mild form, are not even aware they have the condition until tested at older ages, since the vision in their

stronger eye is normal. However, people who have severe amblyopia may experience related visual disorders, most notably poor depth. Amblyopic patients may suffer from poor spatial acuity or low sensitivity to contrast (4).

The health-related quality of life (HRQoL) implications of amblyopia are specifically related to amblyopia treatment, impact on family life, social interactions, difficulties in undertaking daily activities, as well as feelings and behavior (5,6). The impact of amblyopia on HRQoL has not been adequately explored (7). Existing patient reported outcome (PRO) measures for amblyopia do not meet current recommendations for the methods adopted during their development, or the way in which the instruments are administered. One study was to produce a self-complete PRO instrument for amblyopia for children aged 4–7 years that uses children's responses in the development phase (8).

Currently in Romania there is high interest in preventing amblyopia but there are no studies on the quality of life of amblyopic children. A study on the quality of file in glaucoma patients has been published (9).The aim of this study was to produce a pediatric disease-specific HRQoL instrument for amblyopic children to be used in research or routine clinical practice.

MATERIAL AND METHOS

This is a prospective observational transversal study of 44 patients examined and followed-up in the outpatient Ophthalmology Clinic of the Iasi l "Sf. Spiridon" Hospital and Iaşi Stereopsis Ophthamology Clinic over a 12-month period (January – December 2013). The mean age of children with amblyopia was 8.1932±2.9278 years (range 4-16 years). It must be noted that most of the patients were aged 5 to 10 years at the time of the survey, which corresponds to peak detection of amblyopia cases. The mean age of children at the first presentation to the ophthalmologist (which in most cases coincided with the date of the questionnaire) was 3.9091±2.1597 years (range 3 months-7 years). This age was lower in children with highly educated parents. The mean age at the time of diagnosis was 3.9091±2.1597 years (range 1- 7 years).

Parents/tutors of selected children diagnosed with amblyopia were asked to fill out a 46 item questionnaire aimed at measuring the quality of life of parents and especially of children with amblyopia. The clinical parameters recorded during the first examination were: visual acuity (uncorrected and corrected), objective refraction, type of optical correction, binocular vision, ocular motility. Data were statistically processed using Student t test, correlation coefficient – r and p – value.

RESULTS

The following refractive and ocular changes were found: ocular deviation (mainly esotropia) in 45.45% of children, refractive amblyopia in 37% and amblyopia in 14% of cases. Anisometropia was the causes in 13.63% of cases (most commonly hyperopic or myopic in two cases), percentage higher than recent estimates in the literature.

In 93.18% of patients a treatment had been previously recommended by an ophthalmologist. It consisted of optical correction (spectacles or contact lenses) in 88.64%, surgical treatment was performed in 11.36% of cases, and occlusion (covering of the dominant eye) was used in 63.64% of cases. More than half of the

cases associated two or three types of treatment. As to treatment by optical correction (fig.1a and b), in the right eyes (RE) we found: hyperopia in 14.77% of cases (7 cases with mild hyperopia and 5 cases with moderate hyperopia), only 2.27% presented moderate myopia and 25% had mixed astigmatism, mean spherical equivalent = 2.9286±1.4772 diopters (range 0.75-6.25).

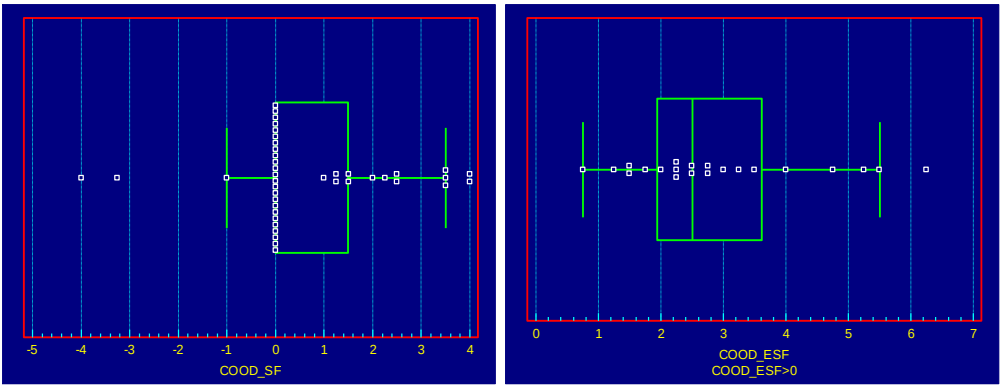

Fig. 1. a and b. Dioptric range of optical correction - RE

In the left eye (LE) we observed (fig. 2a and b) hyperopia in 17.04% of cases: 7.95% mild hyperopia and 9.09% moderate hyperopia (range 3.5 – 6 diopters). In 2.27% of cases we found mild myopia (-1.25) and moderate myopia (-5.25) and 21.59% had mixed astigmatism, mean spherical equivalent 2.9079±1.5097 (range 0.75- 6.5 diopters).

Refractive amblyopia caused by the presence of anisometropia was present in 6.81% of the eyes (tab. I).

There were cases that had more than 2 diopters of cylinder. Mean right eye (RE) uncorrected visual acuity (VA) was 0.4516±0.3104 (range 0.02-1), and the corrected one (with spectacles or contact lenses) 0.6334±0.3161, range 0.08-1 (correlation coefficient r=0.9195 and p <0.0001- statistically significant) (fig. 3).

In the left eye (LE) mean uncorrected and corrected visual acuity were (fig. 4): 0.4909±0.3378 (range 0.00041-1) and 0.6977±0.3225 (range 0.0004-1), respectively (correlation coefficient r=0.8701, p <0.0001- statistically significant).

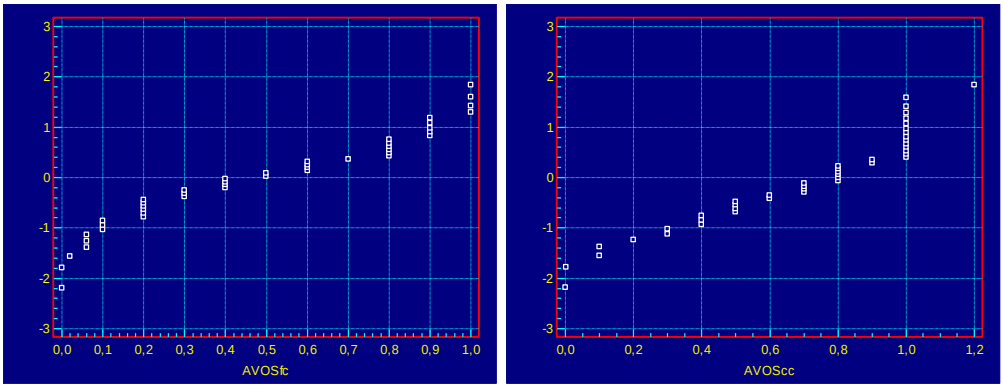

Fig. 4. LE Visual acuity without and with correction

According to the information obtained following the processing of data collected from the questionnaire administered to parents, the main symptoms for which parents sought eye care were: strabic deviation – 45.45%, difficulty seeing the blackboard – 11.36%, and difficulty in seeing closer - 20,45%. Of the parents who filled

out the quality of life questionnaire of their child with amblyopia, most were females (56%), age range 21-50 years (70.45% aged 31 to 50 years). Parental level of education: the majority completed high school (34.09%) or academic education (31.82%). The questions were answered by parents if they spent most of their time with their child (50% of parents) or a family member (grandparents, aunts).

Responses to the questionnaire revealed the following: most parents believed that their child health was very good, binocular VA was good (even though VA was very low in one eye), visual acuity of the good eye was reasonable. Most caregivers said they were concerned with child's vision and eye health spending long time with him/her most weekdays at the expense of time spent with their own family, in other words a form of sacrifice for the greater good. In relation to social life, the children were generally happy and enjoyed the attention received from the caring parents. They tend to bond easily and prefer to play with friends. However in some cases children are excessively shy or nervous, becoming more sociable and calmer after simple optical correction.

Regarding basic daily activities, most parents believe that visual impairment does not affect the ability of their child to recognize faces from a distance, can dress themselves, wash themselves, can ride a bicycle and read their watch or cell phone, can dial a number and manage drinking with a cup. When asked whether the child was in an isolated community, some said that the children remained indoors using computer and watching TV.

As observed from the responses to the questionnaire, children loved to read but it was difficult for them to find certain object in dark places, and commitment to treatment was not so good due to the child disliking it or forgetful or busy caregivers. Before treatment 84.09% of parents were aware that the child had poor school results.

Family support is important as it is related to treatment compliance. Amblyopia therapy is influenced by both the child and the parent/guardian. Whilst the child may object to the wearing of glasses or a patch on a personal level, a parent's perspectives can influence the success of such treatment.

DISCUSSION

Some Quality of Life instruments used in the identified studies were derived from consultations with ophthalmic professionals and/or parents of children with amblyopia. Therefore, the items included in the instrument design, are deemed to be of importance from an adult perspective (10). The included items may be of importance to adults but not necessarily to the child. For example, a parent may feel that educational attainment and the ability to see well at school is of great importance; however, this view may not be shared by the child. In some of the identified studies, the reported findings are taken from a parental perspective (5).

It is not possible to state that the impact of amblyopia treatment felt by the child is the same as that perceived by adults on how, or what the child should feel or experience. Some of the questions asked included how well the child could see whilst undertaking treatment. The parent/guardian cannot directly assess this; they can only make a judgment on how they perceive the child is able to see whilst on treatment. Their judgment could be influenced by how important they judge the activity to be (such as school work or interacting with friends).

Treatment compliance in amblyopia therapy is influenced by both the child and the parent/guardian. Whilst the child may object to the wearing of glasses or a patch on a personal level, a parent's perspectives can influence the success of such treatment. This may incorporate their own experiences or impressions of patching/glasses-wear, or their understanding of the condition and the importance of treatment. Parental understanding of the condition and belief in the prescribed treatment are key components for good treatment compliance (11). However, parents can be well-informed and positive, yet compliance may still be poor. Another argument against using treatment compliance as a measure of quality of life is that a child may consent to wearing the patch but their daily activities and social interactions may still be affected.

Amblyopia it is commonly treated with patching of the nonamblyopic eye, preferably before the age of 6. Approximately 1/3 of the affected children do not reach visual acuity of 6/12 in the amblyopic eye, thereby increasing the risk of bilateral visual impairment due to loss of vision in the nonamblyopic eye and decreasing quality of life in adulthood. A lot of studies have suggested that one of the factors influencing outcome with treatment is the level of compliance (12-22). Low compliance was found to be associated with social deprivation (23) and lower attendance rates were reported among amblyopic patients from more deprived areas (24).

CONCLUSIONS

1. The first presentation to the ophthalmologist was at age 3.9091±2.1597 years (range 3 months -7 years). The sooner the amblyopia is diagnosed and treated, the better the results are regardless of amblyopia type. Health education for seeking attention from an ophthalmologist not later than age 3 is needed.

2. The main symptoms that determined the parents to seek eye care were: strabic deviation (45.45%), difficulty seeing the blackboard (11.36%), and difficulty in seeing closer (20.45%). It is difficult for a child to integrate into school and community but sometimes only after optical correction, the situation improves being reflected in his results.

3. Most parents believe that child health is very good, binocular VA is good (despite a very low VA in one eye), and VA of the good eye is reasonable. Quality life questionnaires detect life or school problems of children with amblyopia and educate parents. In 15.91% of parents they did not knew that before treatment the child had poor school results.

4. This study work represents a first step in Romanian ophthalmologists concern for socio-professional integration of children with amblyopia, because as we know some jobs require healthy eyes and for those who do not receive an appropriate treatment at a young age their dream will be denied.

A POSSIBILITY TO IDENTIFY THE VEHICLE DRIVER THROUGH COMPLEX FORENSIC AND CRIMINALISTIC EXPERTISE – CASE REPORT (Abstract): Traffic accidents can have more or less dramatic consequences that involve penal and civil responsibility with amplitude extending over long periods of time. In many cases, substitution of the driver with the passenger in order to avoid criminal responsibility is often remarked. The substitution takes place with the passenger's agreement or, in cases with dramatic consequences (coma or death), without his/her consent. These situations are encountered in civil cases regarding insurance fraud. In addition to forensic medical expertise, to aid the experts, mathematical modeling and computer simulation of the dynamics of vehicle passengers is a tool that completes the criminal expertise of traffic accidents. This paper presents the method of identification of the person driving the vehicle based on the computer simulation of vehicle occupants' dynamics. **Keywords**: EXPERTISE, TRAFFIC ACCIDENTS, COMPUTER SIMULATIONS

Identification of the vehicle driver is usually accomplished by correlating the injury panel with the vehicle marks (1). These marks can be shape marks, trace substances, biological traces, imprints, etc.

In some cases, individuals assume the fault for an accident without considering long-term consequences. After the case shapes towards a solution, they realize they must face long-term consequences and restate their initial positions. Since a significant amount of time lapses between the date of the traffic accident and the date of the new investigation, during which the vehicle was repaired, totaled or changed ownership, and also due to the fact that the victims were buried or the wounds healed without marks, an answer is difficult to obtain based solely on forensic medical certificates. There could be cases where one of the occupants of the vehicle was projected from the vehicle, and if deceased, the driver may substitute to the passenger in order to be exonerated. In these circumstances, computer simulation of the traffic accident may offer additional information to strengthen the outcome of forensic expertise, and it may even provide answers in cases where forensic expertise is incon-

clusive.

Computer simulations of traffic accidents

Computer simulation of traffic accidents involves correct input of dynamic and physical parameters into a mathematical model. Some parameters are already known while others are found through iterative trials. Mathematical modeling involves a large number of calculations, impossible to accomplish without a computer. If correctly chosen, input parameters, correlated with the shape of the vehicle and the road geometry must yield results coinciding with the real life situation via mathematical modeling. For example, tire marks, final vehicle positions and their trajectories must coincide with those documented by on site investigation.

Here we present a modeling approach using V. Crash 2.2 software. For mathematical modeling of occupant's dynamics as well as in the case of simulations of pedestrian accidents, the V. Crash software takes into consideration higher rigidity coefficients of the vehicle parts as compared to those of the human body and therefore considers as negligible the vehicle deformations.

The model used is composed of a group of ellipsoid bodies which make up the humanoid somatic structure.

Nagoya University researchers (2) developed a mannequin build up of ellipsoid parts (fig. 1) and a mathematical model based on statistics of Japanese population. Based on these data, a model was developed based on the 50est percentile of an adult man (Polar II (3)) whose height was determined at 175 cm and body weight of 75 kg. The sitting height of Polar II mannequin is 88.4 cm. The mannequin used by V. Crash simulations has 16 joints which interconnect 15 hyper-ellipsoids, corresponding to human body parts and their associated degrees of freedom.

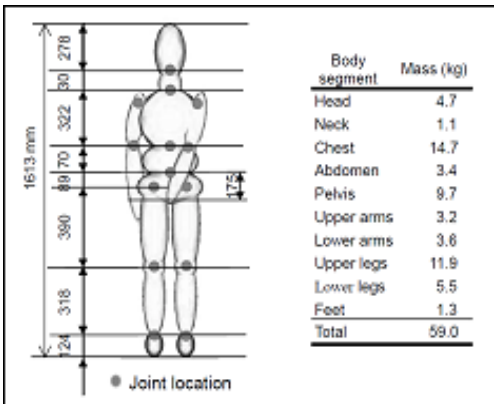

Fig. 1. Japanese model of test mannequin

CASE STUDY

A group of young individuals were inside a vehicle (make Renault, model Megane) moving on an asphalt county road with shoulders and ditches. The motorway was covered with snow and spots of ice. Suddenly the driver lost control of the vehicle and entered the ditch on the right side of the road where it rolled over on the right side and hit the end of a concrete bridge. Following the accident all four occupants suffered injuries (fig. 2, 3).

Several people proceeded to the site and helped pulling the occupants out of the vehicle. Eye witness declarations coincided only in part with the occupants statements. The identity of the occupants on the back seat and their respective positions were confirmed unequivocally, however, regarding the driver and the front passenger, the declarations of the witnesses were contrary to the statements of the vehicle occupants. A forensic medical expertise was ordered in this matter but the investigation did not establish which of the occupants were,

respectively, the driver and the passenger. Therefore, judicial organs ordered a criminalistic expertise whose sole objective was to establish the identity of the driver.

Fig. 2. The vehicle seen from behind

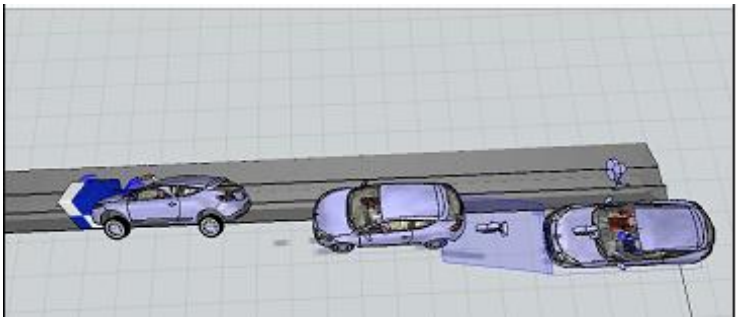

Fig.3. Overview of accident dynamic

The injury profile of the back seat passenger on the right side showed remarkable similarities with that of one of the front seat occupants. Both had lesions of the right fist and right forearm as excoriations and cut wounds. The passenger in the right back seat had a foreign body at the level of the right distal epiphysis (glass fragment) while the front passenger had a fracture of the distal epiphysis (fig. 4).

The front seat occupant suffered an elongation of the right brachial plexus with right acromial – clavicle disjunction (fig. 5), paresthesia of the right arm and shoulder, jaw wound, multiple excoriated and cut wounds at the level of the face, which required 30 – 35 days of medical care.

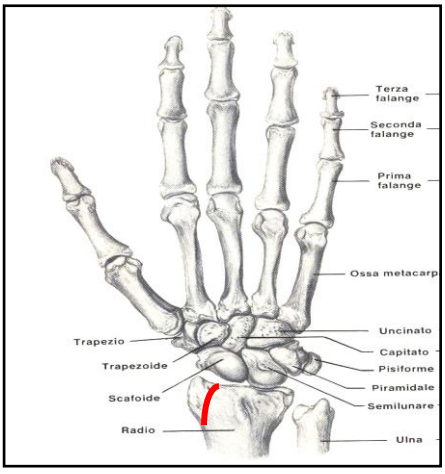

Fig. 4. Right distal epiphysis fracture (marked with red line – according to attached Rx)

The elongation of the brachial plexus is engendered by anterior-posterior hyperextension of the arm that is through front-to-back movement of the arm over the normal limit. This kind of trauma produces the swelling of the shoulder joint with injury of the vascular and nervous bundles with shoulder paresthesia of the shoulder.

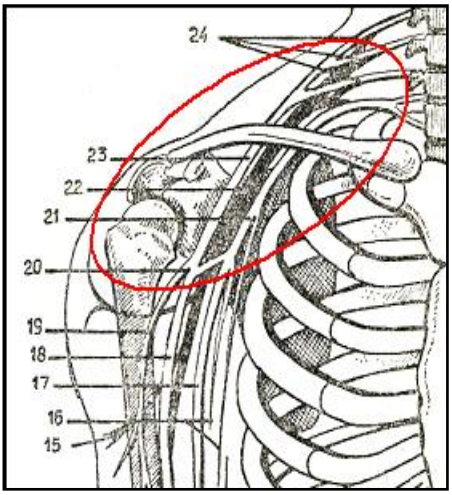

Fig. 5. Diagram of the brachial plexus and its innervation (positions 22-24).

The Rx administered as evidence in the case, obviating the elongation of the brachial plexus and acromial-clavicular disjunction

The injuries suffered by the other occupant were minor and consisted of cut wounds at occipital and upper lip levels. Spots of reddish-brown liquid were found on the vehicles which were later identified as human blood (fig. 6, 7). The blood in the back belonged to the O group while the one in front to group A.

The occupant of the back seat was the brother of one of the front seat occupants and it was assumed that both brothers may have the same blood group. For unknown reasons, until the date of ordering the expertise, the blood group of the brother of the individual occupying the right back seat was not administered as evidence in the case.

Fig. 6. The front seat where samples of reddish brown liquid were taken

Fig. 7. The right back seat where blood traces were sampled

Starting from the data yielded by the minutes of the site investigation regarding the geometry of the road, computer simulations of the accident was performed using V.Crash software. The speed at the impact with the concrete bridge was relatively low, under 10 km/h, as demonstrated by the integrity of the front bumper (fig. 8)

Fig. 8. Aspect of the front side of the vehicle

The injuries suffered by the vehicle occupants were due for the most part to rolling over and not to the impact with the concrete bridge. Following the simulation, starting from a speed of 55 km/h an impact speed of approximately 3.4 km/h was obtained and it was found that the dynamics of the front seats occupants coincides with a dynamic that could produce the injuries suffered by the two occupants, the driver being affected to a minor degree.

Starting from the initial position (fig. 9), front seat occupants were placed and the safety belts were deactivated.

During the first phase of the vehicle rolling over on the right side, it was found that the driver suffered head injuries, due to contact with elements inside the vehicle (fig. 10).

Immediately following the rollover, the passenger on the right suffered injuries at the level of the external aspect of the right hand at the level of the joint (fig. 11). Similarly, these injuries inflicted to the back seat passenger on the right.

Finally it is found that the driver falls over the passenger on the right provoking the brachial plexus dislocation at the level of the right shoulder (fig. 12).

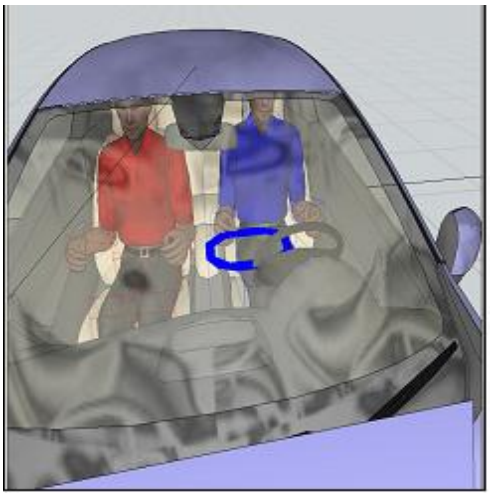

Fig. 9. Starting position of the computer simulation

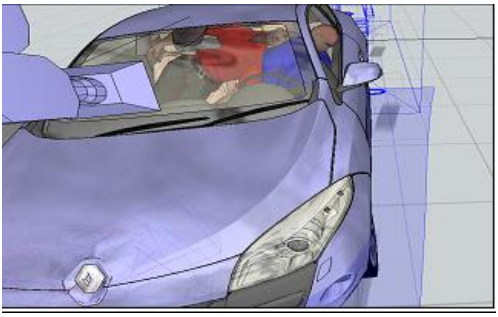

Fig. 10. Impact of the driver with elements inside the vehicle

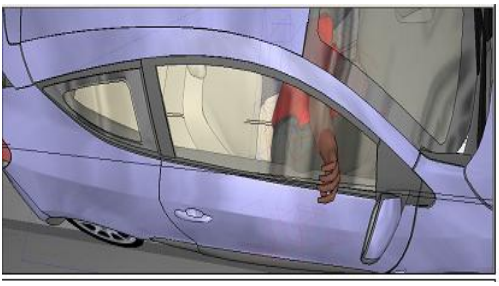

Fig. 11. Hyperextension of the right arm of the passenger of the right and impact of the right arm at the level of the radial-cubital-carpian joint with the right window and later with the dashboard

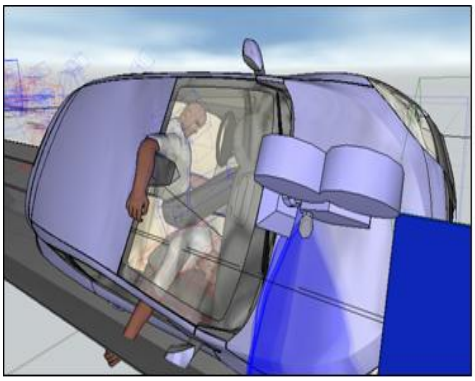

Fig. 12. The mechanism of right brachial plexus dislocation of the passenger

Although during testimonial investigation the passenger and the driver state that they inversely occupied the places in the vehicle, witnesses declarations proved to be true, with computer simulation through mathematical modeling being a sufficiently solid argument towards this conclusion.

CONCLUSIONS

In cases where the driver of the vehicle is unknown, in addition to the injury panel, computer simulation of the traffic accident becomes a very useful and often essential tool.

EPIDEMIOLOGICAL ASSESSMENTS ON INCIDENCE OF ACUTE GASTROENTERITIS IN 0-14 AGED CHILDREN, IN THE IASI COUNTY, ROMANIA, BETWEEN 2009-2012 (Abstract): The study **aim** was to assess the epidemiological potential of acute gastroenteritis (AGE) in children between 2009 and 2012. **Material and methods**: We studied two groups; first, a lot of 7237 cases (*group A*) recorded in the Iasi County through passive surveillance system, reported monthly by the network of primary health care, the assisted outpatients, respectively, those reported by hospitals. The second group (*group B*) was composed of 4191 hospitalized cases reported also in the passive surveillance system m by telephone, weekly, during only June / end of May to October / beginning of November. Structural peculiarities of the two groups are due to different reporting methodology, so that they were analyzed separately. **Results**: AGE cases come from urban or rural areas in relatively stable proportions and slightly increased in rural areas compared to urban. The distribution by sex of cases from the group B is maintained at the same shape from one year to another, with a slight predominance in males. The best represented age group in every studied was 0-3 (54.3% of all cases), followed by children between 5 and 10 years with 17.5%). Laboratory investigations have enabled the etiologic diagnosis for hospitalized cases, which ranged from 15.3 to 17.5%, with the exception of 2009 when the diagnosis was noted for almost half of the discharged patients (47.5%). **Conclusions**: AGE remains a public health problem in the Iasi County and Romania also, by affecting all age groups, but especially children under 3, an insufficient knowledge of the etiology, and economic losses insufficiently evaluated. **Keywords:** ACUTE GASTROENTERITIS, CHILD, SURVEILLANCE

Acute gastroenteritis (acute diarrheal disease, AGE) is a widespread disease worldwide in all age groups, responsible (after common acute infections of respiratory tract) of a large number of consultations in primary care network, but high levels of school and employment absenteeism (which include sick child care leave) (1, 2, 3). AGE in developing countries remains an important cause of death among

children, especially aged 0 to 5 years. Annually, worldwide, approximately two million deaths in children in the age group 0-5 years are reported. AGE mortality in developed countries is no longer a health emergency to the population, although the admission rate is high, causing significant economic losses (4, 5).

Many of episodes are not found in AGE reports, even in industrialized countries, due to the inaccuracy of reporting and under diagnosed. In the United States, where it is estimated that annually produces about 5 million cases of AGE, in fact are reported only 4 million (6, 7, 8, 9, 10, 13). In Romania, AGE cases are reported monthly, cumulating data provided by family physicians and hospitals and during the seasonal epidemiological surveillance, the reporting is made by telephone, weekly. In 2008, AGE surveillance methodology in Romania has changed so that only hospitalized cases were reported between 2009 and 2012.

MATERIAL AND METHODS

The study aim was to assess the epidemiological potential of AGE in children between 2009 and 2012. Thus, we studied two groups; first, a lot of 7237 cases (*group A*) recorded in the Iasi County through passive surveillance system, reported monthly by the network of primary health care (family physicians), the assisted outpatients, respectively, those reported by hospitals. The second group (*group B*) was composed of 4191 hospitalized cases reported also in the passive surveillance system m by telephone, weekly, during only June / end of May to October / beginning of November. Structural peculiarities of the two groups are due to different reporting methodology, so that they were analyzed separately.

The database was performed in Excel software. Statistical analysis was performed with *SPSS 16.0*. For comparison, we used the $\chi 2$ (chi-square). The value of p (significance threshold), which reflects the probability that the difference between analyzed variables is randomly, was considered greater than 0.05.

RESULTS AND DISCUSSION

AGE cases come from urban or rural areas in relatively stable proportions and slightly increased in rural areas compared to urban (values between 51.5 and 54.8%) (tab. I).

TABLE I

Distribution of AGE cases from group A in relation to residence area (Iasi County, 2009-2012)

Year	Total	urban		rural		p
		No.	*%*	*No.*	*%*	
2009	1306	830	**63.5**	476	**36.5**	<0.01
2010	1571	717	**45.6**	854	**54.4**	>0.05
2011	2103	951	**45.2**	1152	**54.8**	>0.05
2012	2257	1008	**44.7**	1249	**55.3**	>0.05
Total	**7237**	**3506**	**48.5**	**3731**	**51.5**	>0.05

Changing in AGE reporting methodology in 2008 to 2009 was followed by recording higher proportion of cases from urban areas (63.5%) in 2009, but in coming years,

the situation is comparable to previous years before those modifications. It notes, however, that the absolute number of reported cases increased in both urban and rural areas (from 978 and even 640 reported cases in 2007-2008, 1306 subjects in 2009 to 2,257 cases reported in 2012) (fig. 1).

The distribution by sex of AGE cases from the group B (phone reporting between June and October) is maintained at the same shape from one year to another, with a slight predominance in males (fig 2).

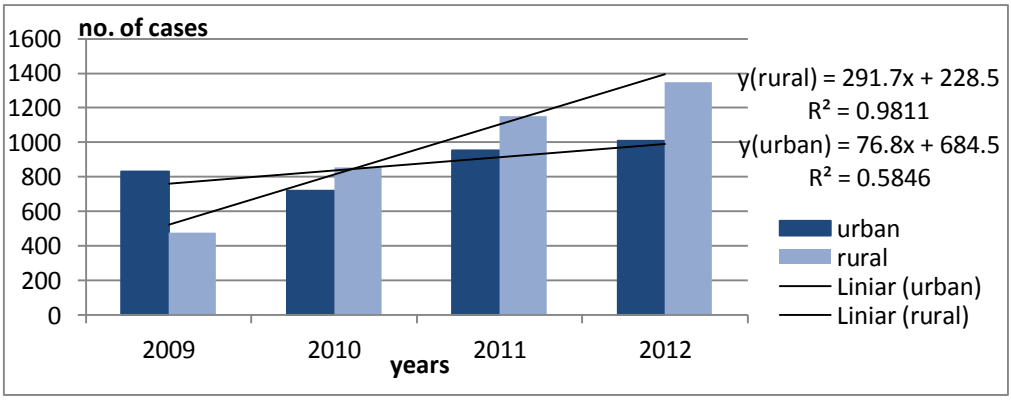

Fig. 1. Distribution of AGE cases from group A in relation to residence area (Iasi County, 2009-2012)

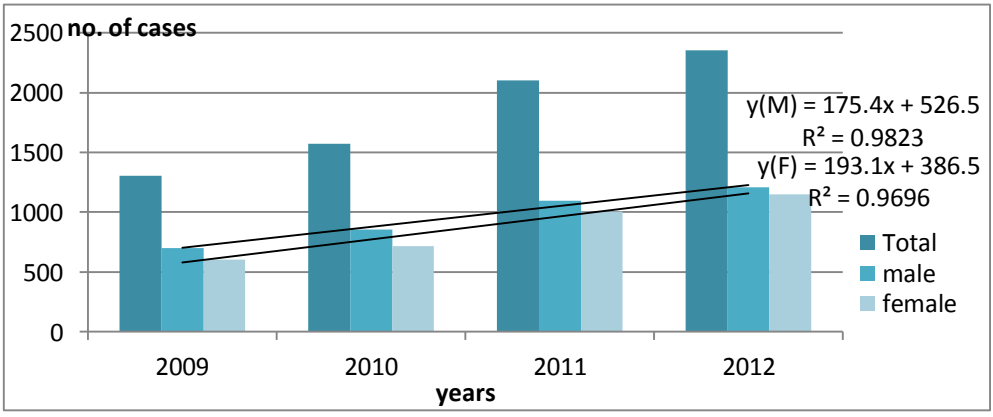

Fig. 2. Distribution by sex of AGE cases from group B (Iasi County, surveillance period June – October, 2009-2012)

The best represented age group in every studied was 0-3 (54.3% of all cases), followed by children between 5 and 10 years with 17.5%), according to data from the literature (7, 8, 9, 10, 11) (tab. II, fig. 3).

Risk factors such as the hygiene status and intra-familial transmission, or gastric hypoacidity and antibiotic treatments could be add an increased vulnerability to any type of infection, including the digestive system and the immune system immaturity specific in children at 3 or younger (15, 16).

TABLE II

Distribution by age of AGE cases from group B (Iasi County, surveillance period June – October, 2009-2012)

Regarding the distribution of the months included in the report, most cases were reported each year in June, July and August (tab. III, fig. 4). The difference of the reported cases by age group in the summer months is statistically significant ($p < 0.05$).

In the group B (season reporting), a large cluster of AGE cases is noticed in the summer months (70.5% of cases in 2009,

64.0% and 64.7% in 2010 and 2012); only 59% of cases were recorded in the summer months of 2011, most cases are concentrated in August and September, contrary to previous years. In the same group B, a number of 1131 of AGE cases with a peak in August is reported in 2012. A higher number of cases reported in 2009 and 2012 in the Iasi County did not follow the trend of the situation at the country level; in contrast, a smaller number of cases reported in the Iasi County in 2010 did not reflect the situation at national level, with greater number of diseases to other years (tab. IV).

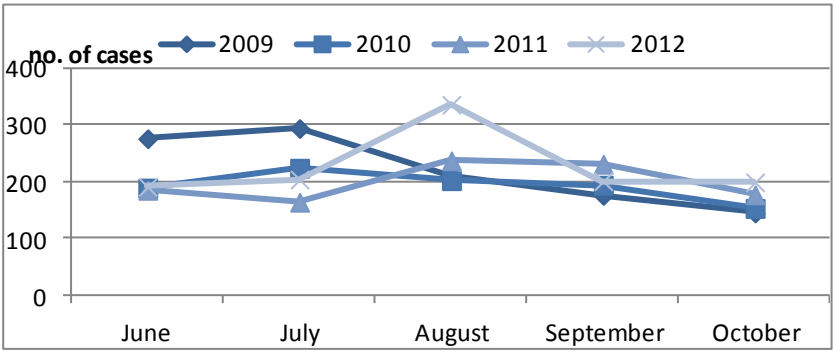

Fig. 4. Distribution of AGE cases from group B in relation to the month of discharge (Iasi County, surveillance period June – October, 2009-2012)

TABLE IV

Number of AGE cases registered in Romania and Iasi County, phone reported during the seasonal surveillance, June – August, 2009 – 2012

Year	Romania	Iasi County	
		No.	%
2009	39,649	1104	2.8
2010	41,651	962	2.3
2011	35,172	994	2.8
2012	36,962	1131	3.0
Total	**153,434**	**4191**	**2.7**

Etiologic diagnosis of AGE cases is a challenge for the epidemiologist, clinician, and laboratory physician (15, 17, 18). Laboratory investigations have enabled the etiologic diagnosis for hospitalized cases, which ranged from 15.3 to 17.5%, with the exception of 2009 when the diagnosis was noted for almost half of the discharged patients (47.5%). Greater attention and better clinical guidance referred to samples from children 0-1 children in which the percentage of positivity is somewhat higher than other age groups (tab. V).

TABLE V

CONCLUSIONS

In the Iasi County, acute gastroenteritis recorded averages values, comparable to other counties from Romania, representing between 2.3 and 3% of all cases reported nationwide.

Seasonal surveillance highlighted a cluster of AGE cases in the summer months (June, July, and August).

The etiologic diagnosis was not possible for most laboratory tests, but the 0-1 age group positivity rate is higher.

Acute gastroenteritis remains a public health problem in the Iasi County and Romania also, by affecting all age groups, but especially children under 3, an insufficient knowledge of the etiology, and economic losses insufficiently evaluated.

INFLUENCE OF ANTIBIOTIC THERAPY PRIOR TO ADMISSION ON THE EFFICACY OF CLASSICAL METHODS FOR THE DIAGNOSIS OF MENINGOCOCCAL DISEASE (Abstract): **Aim:** To assess the influence of preadmission antibiotic therapy on the results of the classical methods for bacteriological confirmation of meningococcal disease (MD). **Material and methods:** Retrospective study of the MD cases diagnosed in the "St. Parascheva" Universitary Clinical Infectious Diseases Iași between 1994 and 2011. **Results:** The etiological diagnosis was made by identifying the meningococcus in the CSF (cerebrospinal fluid) in 71.9% of the 323 patients and by blood culture in 8%. Preadmission antibiotic therapy received 39% of the patients, thus the sensitivity of test was significantly reduced: direct examination from 64.6% to 43.2% ($p < 0.001$), cultures from 55.9% to 27.2% ($p<0.001$), and latex-agglutination from 84.6% to 58.8% ($p=0.003$). The rate of positive CSF decreased from 82.1% to 56% ($p<0.001$). Preadmission antibiotic therapy significantly increased the ratio of cases in which meningococcus was not detected in CSF by any of the classical methods (44% compared to 17.9% in the cases without prior treatment). The proportion of cases in which meningococcal isolation was done by two methods decreased from 38.5% to 19.2%, and of those by all three methods from 16.9% to 5.6% ($p<0.001$). Preadmission antibiotic therapy also decreased the rate of positive blood cultures from 14.7% to 3.5% (Fisher's exact test, $p=0.009$). **Conclusions:** Antibiotic treatment prior to admission significantly decreases the percentage of patients with MD in which meningococcal isolation can be done; this requires the use of a more sensitive diagnosis method (ex. qPCR). **Keywords**: MENINGOCOCCAL DISEASE, PREADMISSION ANTIBIOTIC THERAPY, DIRECT CSF EXAMINATION, CSF CULTURE, BLOOD CULTURE

Meningococcal infection is a leading cause of morbidity and mortality worldwide. It is a disease with lethal potential, which begins suddenly and death can occur within hours. The disease may be present in various forms, from the simple rhinopharyngitis to severe purpura fulminans. All levels of severity are possible within these extremes. Meningococcal meningitis and meningococcal septicemia (meningococcemia) are more frequently drawing the attention of clinicians. The disease has a

higher mortality rate in case of delayed diagnosis and treatment.

Early diagnosis is essential for therapeutic success. Meningococcal disease is normally suspected on clinical grounds and confirmed by laboratory tests. Still, the clinical diagnosis of meningococcal disease can be difficult because of symptom variability. Furthermore, in order to improve the prognostic, in cases suspected of meningococcal infection, the current guidelines recommend the administration of an antibiotic as quickly as possible, sometimes even before arrival at the hospital (1).

MATERIAL AND METHODS

The present study aimed at assessing the influence of antibiotic therapy administered prior to admission on the results of classical methods for bacteriological confirmation of meningococcal disease in the cerebrospinal fluid (CSF) (direct examination, culture and latex agglutination), blood (blood culture) and pharynx (throat swab). This is a retrospective analysis which included the cases of meningococcal disease diagnosed in the „St. Parascheva" Universitary Clinical Infectious Disease Iaşi between 1994 and 2011. We analyzed the etiologic diagnosis [identification of *N. meningitidis* in CSF (direct examination, culture and latex agglutination (LA), blood (blood culture) and pharynx (throat swab)] in relation with the absence or presence of preadmission antibiotic therapy.

The database was created in Microsoft Access. The statistical analysis was performed using SPSS 17.0. The differences between groups were calculated with the help of χ^2 test, Fisher exact, with a significance threshold of $p < 0.05$.

RESULTS

During the study period (1994–2011) 323 cases of meningococcal disease were recorded, 80% (257 cases) being cases of meningococcal meningitis and the remaining 20% (66 cases) meningococcemia cases. The etiologic diagnosis was made in the Laboratory of the "St. Parascheva" Universitary Clinical Infectious Diseases Iaşi. 320 CSF specimens, 248 blood cultures and 288 throat swabs were obtained from the 323 patients with meningococcal disease. All 320 CSF specimens were tested by direct examination and culture, but CSF latex agglutination (LA) was performed in only 122 cases. The macroscopic appearance of CSF was purulent in 58% of the meningococcal disease cases and clear in 18%. Classically, CSF was purulent in most cases of meningococcal meningitis (67.8%) and clear in most cases of meningococcemia (69.2%). The etiologic diagnosis was made by the identification of *N. meningitidis* in 71.9% of the cases. The meningococcus was identified by direct CSF examination in 56.3% of the cases, and CSF culture in 44.7%. The use of CSF LA reaction made the etiologic diagnosis especially in the patients receiving antibiotic therapy prior to the test, in 76.8% of the cases. *N. meningitidis* was identified in CSF by one of the classical methods of diagnosis in 28.4% of the cases. In 30.9% of the patients, the meningococcus was identified by two methods and in 12.5% by three methods. CSF was positive in approximately 72% of the cases. Direct examination was positive in 56.3% of the cases, and the culture was positive on average in 45%; all these percentages remained relatively constant over the study period. The percentage of positive LA tests was high and varied significantly during the study period. Meningococcus was also identified by blood culture in 8% of the cases and in the throat swab in 15%. Thirty-nine percent of the patients received antibiotic therapy prior to admission. The annual distribution of the patients on antibiotic therapy prior to admis-

sion showed an average of 38.7%, relatively constant over the study period. When studying the influence of antibiotic therapy prior to admission on CSF, no statistically significant effects on the macroscopic aspect of CSF were noticed, either in meningococcal meningitis or meningococcemia. On the other hand, the effects on the etiologic diagnosis methods were statistically significant. Thus, the percentage of positive direct examinations decreased from 64.6% to 43.2% by using antibiotic therapy prior to admission (χ^2 = 14.195, p < 0.001) (fig. 1). The percentage of positive CSF cultures decreased significantly from 55.9% to 27.2% (χ2=25.379, p<0.001) in case of prior antibiotic use (fig. 2). The percentage of positive CSF LA test decreased from 84.6% in the absence of prior antibiotic use to 58.8% in the cases of antibiotic therapy prior to admission (χ2=8.84, p=0.003). The rate of positive CSF decreased significantly from 82.1% to 56% when antibiotic therapy was administered prior to admission (χ2=25.57, p<0.001) (fig. 3**).** Antibiotic therapy prior to admission determined a significant increase in the proportion of cases in which meningococcus could not be identified in CSF by any of the classical methods: 44 % compared to 17.9% in the cases without antibiotic use prior to admission. On the other hand, no significant changes were noticed in the cases in which meningococcus was identified by a single method. The percentage of cases in which the meningococcus was identified by two methods decreased as a consequence of prior antibiotic use, from 38.5% to 19.2%. The percentage of cases in which meningococcus was identified by all three methods decreased significantly from 16.9% without prior antibiotic use to 5.6% with antibiotic use prior to admission (χ2= 35.88, df=3, p<0.001) (fig. 4). A decrease in the proportion of positive blood culture from 14.7% to 3.5% due to antibiotic therapy prior to admission was also found (Fisher exact test, p=0.009) (fig. 5). Antibiotic therapy prior to admission had no statistically significant effect on throat swab tests (18.9% *vs.* 15%, χ2=0.7, df=1, p=0.4). The main antibiotics administered prior to admission were penicillin G (17.2% of cases) and third-generation cephalosporins (C3G) (7.5%). No statistically significant differences were found between the effects of penicillin G and C3G administered prior to admission on the etiologic diagnostic methods of meningococcal disease.

DISCUSSION

Neisseria meningitidis (meningococcus) causes a spectrum of disease that varies from the asymptomatic carriage to meningitis and even septicemia (meningococcemia), sometimes with fulminating evolution. Due to the difficulties of early diagnosis and fast progression, the invasive meningococcal disease (sepsis and/or meningitis) is a potentially fatal condition that can also cause long-term sequelae (2, 3). Therefore, fast and accurate diagnosis is essential for optimal management of patients and prompt implementation of preventive measures (4). In meningococcal disease the clinical diagnosis can be difficult due to the variability of symptoms**.** CSF examination (biochemical data and polymorphonuclear cells count) can be useful for differentiating acute viral meningitis from bacterial ones. But the gold standard in the microbiological diagnosis remains *Neisseria meningitidis* culture from sterile body fluid, like blood or CSF. Nowadays, confirming the diagnosis of meningococcal infection by conventional microscopy and culture techniques is becoming increasingly difficult. This is due to the early initiation of antibiotic treatment, which is recommended by current guidelines to improve the management and prognosis (5, 6). Thus, the positive blood culture rate ranges from 25 to 50 % and decreases to about 5 % when antibiotics are administered prior to admission. In our study a decrease in the positive blood culture rate from 14.7% to 3.5% in case of prior antibiotic use. Direct CSF microscopic examination and culture are positive in 80-90% of untreated cases of meningococcal meningitis, but this rate also decreases in case of antibiotic therapy prior to admission, fact also noticed in our study where the effects of antibiotic therapy prior to admission on the etiologic diagnosis were significant (7-10). Thus, antibiotic therapy prior to admission caused a decrease in the rate of positive direct CSF examinations from 64.6% to 43.2% and of the rate of positive CSF cultures from 55.9% to 27.2%. In our study, the rate of positive CSF latex agglutination also decreased from 84.6% in the cases without prior antibiotic use to 58.8% in the cases receiving antibiotic therapy prior to admission. The rate of positive CSF tests in relation with the absence or presence of prior antibiotic therapy decreased significantly from 82.1% to 56%. Furthermore, in many patients a lumbar puncture cannot be performed in early stages of the disease because of the fear of clinical deteriorations

(11). Other limitations of conventional diagnostic methods include the time to culture positivity and the low sensitivity and specificity of the rapid Ag-Ac tests (latex agglutination) (12, 13).

CONCLUSIONS

This study shows that the antibiotic treatment administered prior to admission significantly reduces the percentage of patients with meningococcal disease in which *N. meningitidis* can be identified by standard microbiological techniques. The use of CSF latex agglutination reaction allowed the etiologic diagnosis especially in patients with preadmission antibiotic use. A limitation of conventional diagnostic methods is the relatively long time to culture positivity and low sensitivity and specificity of latex agglutination test. Consequently, the use of a fast and more sensitive diagnostic method is mandatory (qPCR).

THE INFLUENCE OF FUNCTIONAL THERAPY ON FACIAL AND DENTAL STRUCTURES. CASE PRESENTATION

Dana Feştilă[1], M.Ghergie[1], Alexandrina Muntean[2], A. Şerbănescu[1]
University of Medicine and Pharmacy ″Iuliu Haţieganu″ Cluj-Napoca

THE INFLUENCE OF FUNCTIONAL THERAPY ON FACIAL AND DENTAL STRUCTURES, IN CLASS II DIVISION 1 CASES. CASE PRESENTATION (Abstract): In the era of fixed appliances, some orthodontic practitioners seem to forget about functional therapy. Functional appliances are the only capable of orthopedically changes during the growth spurt. Activators of all types, classic or opened, are elected appliances in growing subjects with class II/1 anomalies. The appropriate case selection, along with patient compliance, lead to improved facial aesthetic and dental occlusion, at affordable prices. With this case presentation, we want to show our protocol in the management of these cases. **Keywords:** ACTIVATOR APPLIANCE, FACIAL AESTHETIC, DENTAL OCCLUSION.

Class II division 1 malocclusions through mandibular deficiency are common in Eurocentric societies. Many studies have shown that orthodontic-orthopedic treatment with functional appliances during growth is capable to stimulate the anterior repositioning of the mandible and to correct the occlusion and the facial appearance as well (1-6). The classic activator is one of the most frequent used appliances in class II/1 treatment but one of its disadvantages is the large volume that makes it uncomfortable for the patient. One alternative could be the open activator that allows more lack of restrictions for tongue movements because the acrylic mass is reduced, that′s why it is more comfortable and can be worn almost permanently, not only during sleeping. (7)

CASE REPORT: A 12 years old male with class II/1 malocclusion. Extraoral examination revealed an ovoid facial pattern with short lower face, protruded lower lip and deep labial-mental fold, retrognathic chin and convex profile (fig.1).

Fig.1. Pretreatment extraoral photographs

Intraorally, the canine relationship was half a cusp class II on both sides, the right first molar was in class I and the left first molar was in half a cusp class II relationship. The upper incisors were extremely protruded. The upper right canine was expected to erupt. In the lower arch, there was a little crowding in the front teeth and the curve of Spee was very deep (fig.2, 3). The over jet was of 9.1 mm and the overbite was of 5 mm. (fig. 4).

Fig. 2. Pretreatment photographs of the dental arches

Fig. 3. Pretreatment lateral occlusion

Fig. 4. Pretreatment frontal occlusion

The lateral cephalogram showed a stage 3 in maturity of the cervical vertebrae, what means pubertal growth, the best time for functional treatment; 4 mm skeletal class II, deep bite (FMA angle=20°), upper incisors protrusion (I -Frankfurt line angle=123°) and normal position of the lower incisors (IMPA angle=90°). Gonion angle was decreased (120°),the angle of Y axis with Frankfurt plane was 57° that means an anterior direction of growth.The skeletal and soft tissue profile was convex (NAPog angle= -8.2°, GlSnPog angle= -22°) (fig. 5.)

Fig. 5. Pretreatment lateral cephalogram

The case was treated with an open activator (fig. 6).

Fig. 6. Open activator used

After one year of treatment, the over jet was completely reduced through upper incisor retrusion and mandibular advancement. The overbite was 1/3 with a leveled curve of Spee, because of lower lateral extrusion, that was obtained progressively trimming the lateral acrylic mass. The same appliance was used for retention until the completion of growth (fig. 7).

The skeletal and soft tissue facial profile was substantially corrected into a straight one (fig. 8, 9).

Fig. 7. Post-treatment frontal occlusion

Fig. 8. Tracings of pretreatment (blue) and post-treatment (red) cephalograms

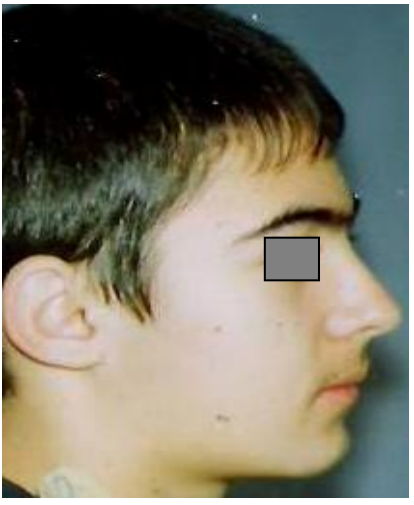

Fig. 9. Post-treatment extra-oral photograph

DISCUSSION

Regarding our case and the existing theories in the literature about functional therapy, properly case selection is a guarantee for successful treatment and good results. The criteria that must be fulfilled are: the skeletal maturation at the peak (pubertal age), distal occlusion in canines and molars, moderate to severe overjet (up to 12 mm), skeletal class II because of mandibular posterior position sometimes associated with mandibular deficiency, deep-bite or normo-bite, mandibular counter clockwise rotation and good patient compliance. (8,9)

The reason for we have chosen an open activator was to allow the tongue to move anterior during the treatment , in the same direction with the mandible determined by the construction bite and to apply in the anterior third of the palatal vault. Also, it is more comfortable for the patient compared with a full, classic one.

SPECTROMETRIC DETERMINATION OF TOTAL ANTIOXIDANT ACTIVITY IN CHLORPROMAZINE RADICAL CATION – ASCORBIC ACID SYSTEM ***(***Abstract). Through univalent oxidation chlorpromazine forms a colored and relatively stable radical cation with maximum absorbance at 525 nm, considered a redox mediator in a number of biochemical reactions. **Aim**: To develop a spectrometric method for the determination of total antioxidant activity based on the reaction of chlorpromazine radical capture by ascorbic acid (standard antioxidant). **Material and methods**: The calibration curve was drawn by monitoring the decrease in the absorbance of the preformed radical solution (obtained by oxidation of chlorpromazine by potassium persulfate in an acidic environment) depending on ascorbic acid concentration**. Results**: The method was validated. In the ascorbic acid concentration range 10-100 μM/L linearity was good (r^2 = 0.9991). Limit of detection (LOD) was 3.13 μM/L and limit of quantification (LOQ) was 9.49 μM/L. System precision (RSD = 0.75%), method precision (RSD = 4.50%) and intermediate precision (RSD = 4.63%) were determined. The average recovery of 101.7% for the concentration range 91.1 -105.9% confirmed the accuracy of the method. **Conclusions**: The method has a good linearity, precision, accuracy, and is easy to use for evaluation of antioxidant action of different products. Total antioxidant activity is expressed as ascorbic acid molar equivalents (AAE). The method has the advantage of using a radical involved in redox processes in the body**.** ***Keywords***: CHLORPROMAZINE RADICAL CATION**,** ANTIOXIDANT ACTIVITY.

In order to assess the antioxidant activity of some products (plants, medicines, food, nutritional supplements, cosmetics, etc.) various methods have been developed, most of them based on the quenching of preformed colored free radicals by the antioxidants in the analyzed samples. The most commonly used free radicals are DPPH and ABTS, but they have the disadvantage of not existing as such in biological environments (1-5).

Chlorpromazine ([2-chloro-N-(3-dimethyl aminopropyl phenothiazine]) forms by univalent oxidation a colored and relatively stable radical cation; it is considered that these radicals are important intermediates in the biochemical activity and metabolism of phenothiazines in general and of chlorpromazine, in particular.

Chlorpromazine (CP) is an efficient peroxidase substrate acting as redox mediator (mediator of electron transfer reactions)

through the cation radicals it forms ($CP^{\bullet +}$). Due to the high reduction potential of CP-$CP^{\bullet +}$ system (860 mV), these radicals exert a pro-oxidant action in the body (6).

It has been demonstrated by UV-VIS and ESR spectroscopic studies that chlorpromazine radical cation is able to oxidize aminopyrine (aminophenazone) to its radical cation (7).

Similarly, chlorpromazine radicals can stimulate the production of toxic intermediate free radicals from various drugs and other xenobiotics.

In this context, chlorpromazine cation radicals, with major implications in biological systems, can be used for the assessment of antioxidant action of various products.

The aim of this paper was to use chlorpromazine radical cation in the development of a simple, rapid and inexpensive spectrometric method for the assessment of antioxidant activity applicable for different products.

MATERIAL AND METHODS

Reagents:

- chlorpromazine maleate (Sigma) 0.01 M aqueous solution;
- potassium persulfate (Merck) 0.001M aqueous solution;
- hydrochloric acid 37% (Farmitalia) 1M solution;
- L(+) ascorbic acid (Merck) standard solution 0.01M. Etalon solution 2.10^{-4} M was prepared by dilution of standard solution at the time of use.

Apparatus:

- UV-VIS Spectrophotometer (Hewlett Packard 8453);
- Analytical balance (Scaltec).

Principle of the method: Chlorpromazine maleate reacts with potassium persulfate in an acidic medium, resulting in radical cation $CP^{\bullet +}$ with absorption maximum at 525 nm. Ascorbic acid captures the chlorpromazine free radicals and determines a decrease in radical solution absorbance; solution discoloration is proportional to ascorbic acid concentration.

Obtaining a calibration curve. In order to prepare a radical solution, for a volume of 1 mL chlorpromazine maleate solution 0.01 M, 8.5 mL 1M HCl and 0.5 mL 0.001M $K_2S_2O_8$ solution were added.

For larger amounts these quantities are multiplied.

20 minutes after adding 0.001M $K_2S_2O_8$ solution, at 2mL radical solution 1 mL ascorbic acid etalon solution was added having in concentrations between 10- 100μM /L. Absorbance of solutions was measured at 525 nm in a 1 cm cell against water.

Method validation. To validate the method the following parameters have been determined: response function linearity, limit of detection (LOD), limit of quantification (LOQ), precision (system precision, method precision and intermediary precision), and accuracy (recovery method) (8).

RESULTS AND DISCUSSION

The analytical domain was studied by determination of optimum ascorbic acid concentration. It was established that good results had been obtained in the concentration range $1.5.10^{-4} – 2.10^{-4}$ M.

The optimum ascorbic acid concentration was 2.10^{-4} M because the slope was greater and the difference between absorbance values was enough in the concentration range considered (fig. 1).

Linear response function was studied in triplicate in the range of 10-100 μM /L ascorbic acid concentration (tab. I).

From the calibration curve, obtained by using the average absorbance values, it could be seen that the developed method was linear

in the analyzed concentration range.

The equation of calibration curve was calculated using the least squares method.

The linearity of results was assessed by plotting the variation in concentration levels calculated by the equation of calibration curve according to theoretical ascorbic acid concentration (fig. 3).

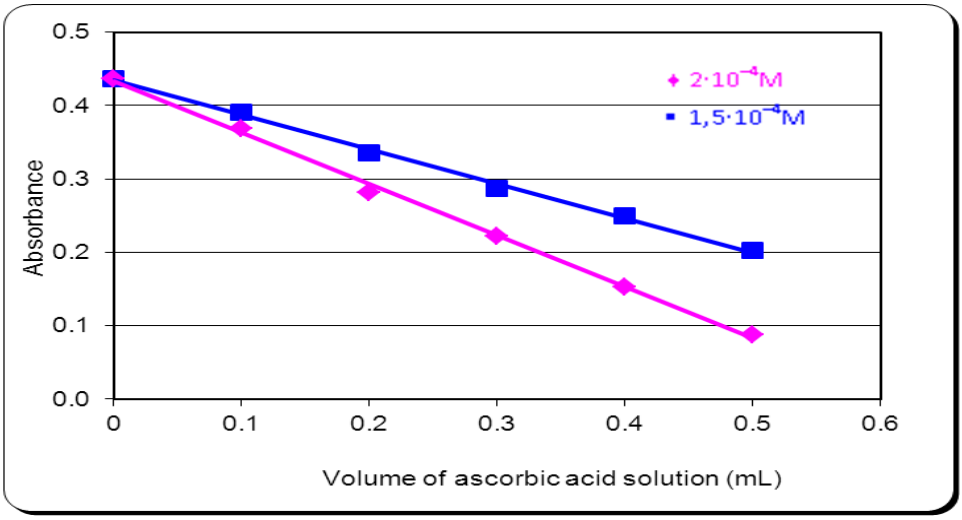

Fig. 1. Analytical domain

TABLE I

Linearity of the method

No.	Ascorbic acid concentration (μM/L)	Absorbance			
		I	II	III	Average
1	10	0.50143	0.49367	0.49991	0.498337
2	20	0.47917	0.48485	0.48152	0.481847
3	30	0.44793	0.48137	0.45829	0.462530
4	40	0.42057	0.45785	0.45164	0.443353
5	50	0.42158	0.41835	0.42021	0.420047

9	90	0.31616	0.38851	0.32778	0.344150
10	100	0.29738	0.38376	0.29846	0.326533

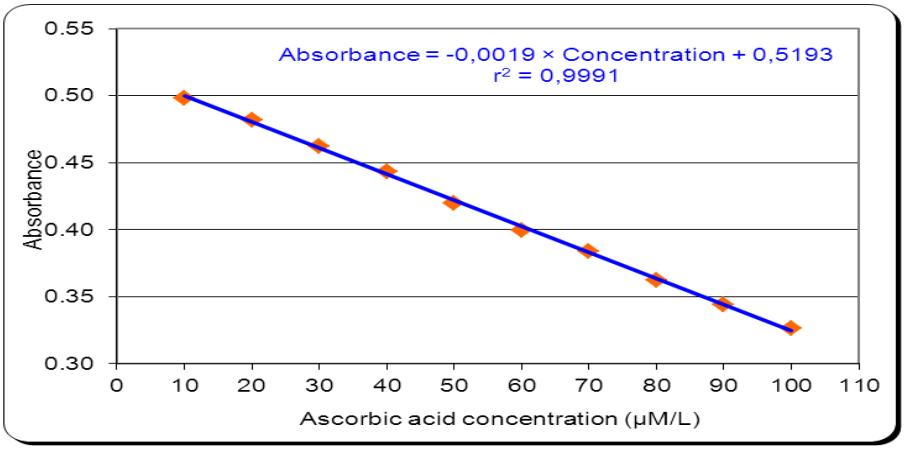

Fig. 2. Calibration curve

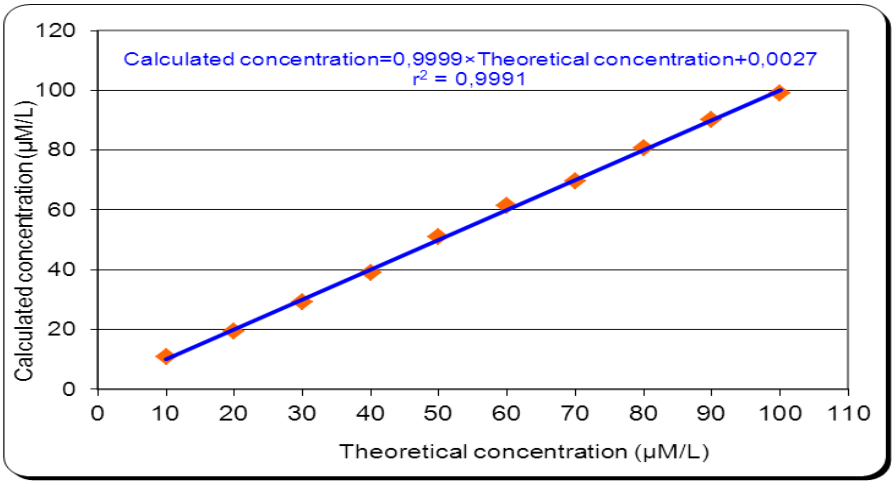

Fig. 3. Linearity of results

It was found that between the calculated and theoretical concentration values there was a linear dependence, the curve slope being 0.9999 and intercept 0.0027.

Limit of detection (LOD= 3.13 µM/L) and *limit of quantization* (LOQ= 9.49 µM/L) were calculated based on standard deviation and slope of regression straight line.

In order to estimate *precision* the following were determined:

- the repeatability of determination (*system precision*) for a number of 10 determinations, the relative standard deviation (RSD) value being 0.7535%;

- the repeatability of analysis (*method precision*) and *intermediate precision* for three assays at three different concentrations values.

Samples concentration was calculated using the calibration curve equation and the percent of calculated concentration from theoretic concentration was established. The results were statistically processed. For intermediate precision determination, this

experiment was repeated on the following day in the same way but with different reagents (tab. II).

From the experimental data we found that in the range ±20% of the value of interest the proposed method was precise, the relative standard deviation (RSD) being less than 5%.

To assess *the accuracy* of the method, a known ascorbic acid concentration was added to a determined amount of ascorbic acid solution. The samples were spectrometrically analyzed and accuracy was calculated based on the concentration of the recovered analyte and that of the added analyte; the recovery for a number of three samples at three different levels of concentration is presented in table II.

TABLE II

Method precision, intermediate precision and accuracy of the method

Nr.	Theoretical concentration (μM/L)	The method precision		Intermediary precision		Accuracy of The method	
		Calculated concentration (μM/L)	%	Calculated concentration (μM/L)	%	Calculated concentration (μM/L)	Recovery %

The data obtained shows that the proposed method is accurate, average recovery being 101.7% in the 91.1% to 105.9% range.

In order to determine the antioxidant activity of some biological products, a certain amount of the sample, obtained by the appropriate processing of the product, is added to 2 mL of preformed radical solution, absorbance is determined and from the calibration curve the antioxidant activity expressed as molar equivalents (micromolars) of ascorbic acid (AAE) per unit of measure chosen for the sample can be estimated.

CONCLUSIONS

The capture of chlorpromazine chromophore radical cation ($CP^{\bullet+}$) by ascorbic acid (standard antioxidant) causes a decrease in the absorbance at 525 nm of the preformed radical solution proportional to ascorbic acid concentration.

Based on this reaction a spectrometric method for the determination of antioxidant activity in the $CP^{\bullet+}$ - ascorbic acid system was developed and validated. The proposed method was linear over the concentration range 10-100 μM/L ascorbic acid. Precision (system precision, method precision and intermediate precision), limit of detection (LOD), limit of quantification (LOQ) and accuracy have been assessed. The obtained experimental data show that the proposed method is sensitive, precise and accurate. The method is simple, inexpensive and easy to use requiring usual reagents and equipment; it can be used to determine the antioxidant activity of medicinal plants (lyophilisate, aqueous extracts, and tea) or pharmaceutical products containing antioxidant components, the result being expressed as ascorbic acid molar equivalent (AAE) per unit of measure chosen for the test sample.

VALIDATION OF A SPECTROPHOTOMETRIC ASSAY METHOD FOR BISOPROLOL USING PICRIC ACID (Abstract): Bisoprolol is a drug belonging to beta blockers drugs used primarily for the treatment of cardiovascular diseases. **Aim:** A spectrophotometric method for quantitative determination of bisoprolol was developed based on the formation of a complex combination between bisoprolol and picric acid. **Material and methods**: The complex combination of bisoprolol and picric acid has a maximum absorbance peak at 420 nm. Optimum working conditions were established and the method was validated. **Results**: The method presented a good linearity in the concentration range 5-120 μg/ml (regression coefficient $r^2 = 0.9992$). The RSD for the precision of the method was 1.74 and for the intermediate precision 1.43, and recovery values ranged between 98.25-101.48%. **Conclusions:** The proposed and validated spectrophotometric method for the determination of bisoprolol is simple and cost effective. **Keywords:** SPECTROPHOTOMETRIC METHOD, VALIDATION, BISOPROLOL, PICRIC ACID.

Bisoprolol is a valuable drug used in the treatment of cardiovascular diseases. It has special pharmacokinetic properties demonstrated by numerous clinical studies.

There are few spectrophotometric methods for the assay of beta blockers and fewer for bisoprolol. Most of the published methods are high performance liquid chromatography (HPLC), liquid chromatography–tandem mass spectrometry (LC–MS/MS), liquid chromatography–electrospray ionization mass spectrometry (LC–ESI, MS) and voltammetry methods (1-12).

This paper presents a spectrophotometric method for the assay of bisoprolol using picric acid as reagent. The developed method was validated by studying the following parameters: linearity, detection and quantification limit, precision and accuracy (13-16).

MATERIAL AND METHODS

Reagents and apparatus:

- bisoprolol fumarate - 100.07% pure, reference substance produced by UniChem Laboratories, LTD, India;
- all the other used reagents were produced by TunicProd, Bucharest, Romania;
- Kern 770 Analytical balance;
- Hewlett Packard 8453 UV-VIS spectrophotometer;
- Ika Vibrax VXR Basic ultrasonic bath.

Solutions:

- 100 μg/ml bisoprolol stock solution:

10 mg bisoprolol were dissolved in chloroform in 100 ml volumetric flask;

- Working solutions containing 5 to 120 µg/ml bisoprolol were obtained by diluting the stock solution with chloroform.

- 0.1% picric acid solution prepared in chloroform.

Principle of the method: bisoprolol fumarate forms with picric acid a complex combination soluble in chloroform with maximum absorbance at 430 nm, proportional with bisoprolol concentration.

In order to establish the optimum wavelength for the detection, 1 ml of the 5 µg/ml and 120 µg/ml working solution were mixed with 1 ml 0.1% picric acid solution. The UV-VIS absorption spectrum was recorded using a 1 cm cell after 25 minutes.

In order to establish the optimum working conditions, two solutions of 5 µg/ml and 120 µg/ml were used (the minimum and maximum concentration of the linear range), while the parameters of the method were changed. The optimum concentration of picric acid solution and the stability of the reaction product were determined.

Procedure: 1 ml of 0.1 % (w/v) picric acid solution was added to 1 ml of bisoprolol in a concentration range of 5 - 120 µg/ml and then stirred for 5 minutes. The absorbance was measured at 430 nm in a 1 cm cell versus a blank solution prepared in similar conditions.

Validation of the method

Detection limit (LOD) and quantification limit (LOQ) were calculated using the following formulas: LOD = 3 x standard error / slope, and LOQ = 10 x standard error / slope (7).

Precision of the method was investigated through its repeatability and reproducibility. Three solutions of 20 µg/ml, 60 µg/ml and 80 µg/ml bisoprolol were used. Three assays were performed for each concentration on the same day in order to assess repeatability. Three sets of assays were performed on different days in order to evaluate reproducibility.

In order to establish the accuracy of the method, bisoprolol solutions of 20 µg/ml, 60 µg/ml and 80 µg/ml were analyzed. For each concentration, three determinations were performed.

RESULTS AND DISCUSSION

The analysis of absorption spectra showed a maximum absorbance for the reaction product at 420 nm (fig. 1). This value was used for all determinations.

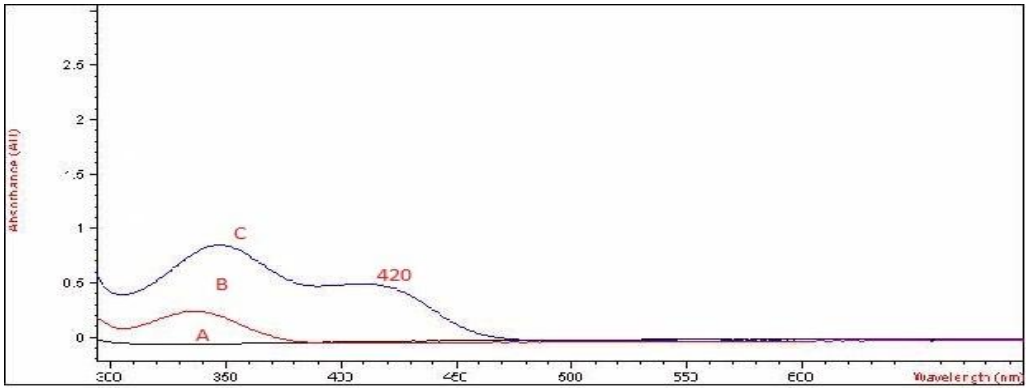

Fig. 1. Absorption spectra for bisoprolol (A), picric acid (B), and reaction product (C)

The optimum concentration of picric acid solution was found to be 0.1 % (w/v) (tab. I).

Absorbance was measured 25 minutes after preparation (tab. II).

Linearity: solutions containing bisoprolol in a concentration range of 5 – 150 μg/ml were used.

The obtained data (tab. III) were analyzed by linear regression (fig. 2) and then a calibration curve was obtained (fig. 3). In conformity with the experimental data, the developed method for bisoprolol determination was linear in 5 - 120 μg/ml concentration range. The parameters of linearity are shown in table III.

Linearity parameters	Range 5 - 120 μg/ml. Intercept = 0.00336 Slope = 0.0113. Correlation and regression coefficient r = 0.9995, r^2 = 0.9992 Detection limit (LOD) = 0.89 μg/ml Quantification limit (LOQ) = 2.97 μg/ml				

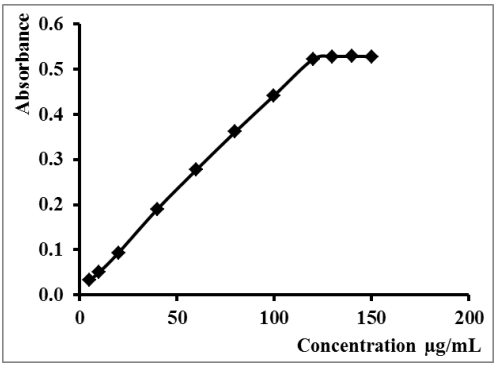

Fig. 2. Linearity

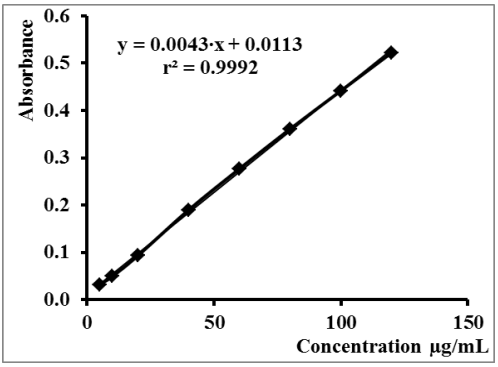

Fig. 3. Calibration curve

The calibration curve equation was: Absorbance = 0.0043 × concentration + 0.0113.

The precision of the method was closely observed through repeatability and reproducibility.

Bisoprolol concentration in the samples was calculated based on the experimental data and calibration curve equation (tab. IV). The relative standard deviation was less than 2%. This fact proves that the proposed method is precise.

Accuracy: sample concentration was calculated based on the experimental absorbance data and the regression curve equation (tab. IV). We noticed that recovery was between 98.64 and 101.08 for the studied concentration range. These values prove that the proposed method is accurate.

TABLE IV

Statistical data	RSD% = 1.74		RSD% = 1.43		Mean = 100.34	

CONCLUSIONS

A spectrophotometric method was developed for the assay of bisoprolol using picric acid as reagent. Statistical analysis proved that the method is repeatable for estimation of bisoprolol as bulk drug.

The proposed method was found to be simple, easy to perform, precise and accurate.

It is a novel method and can be used as a more economic alternative to other spectrophotometric techniques for routine analysis in drug quality control or in laboratory.

CONSIDERATIONS ON THE EPIDEMIOLOGY, ETIOLOGY AND PROFILE OF PERIODONTAL-DENTAL INJURIES IN PRESCHOOL POPULATION IN IAŞI COUNTY (Abstract): In recent years there has been a considerable increase in the number of temporary teeth injuries, this variability being determined by multiple etiologic factors, which we need to be aware of, as well as by predisposing conditions. **Aim:** To characterize the epidemiology, etiology and pathology of specific types of periodontal-dental trauma in a series of preschool children from Iasi County. **Material and methods:** The study included a total of 672 subjects aged 3 to 7 years old, from both urban and rural areas of Iaşi County. Statistical analysis was performed using *STATISTICA* software used in medical research. **Results:** Prevalence of periodontal-dental trauma in the study group was 19.64%. Gender distribution in the study group showed a preponderance of males (62.12%). The risk of periodontal-dental trauma in deciduous teeth was 1.63 times higher in boys compared to girls. Fall accidents (41.67%) closely followed by playground accidents (31.82%) were the most common causes of periodontal-dental trauma in the study group. **Conclusions:** The prevalence of temporary dental trauma in the study group was relatively high, requiring the implementation of oral health promotion strategies and prevention programs, primarily addressed to parents and educators. **Keywords:** PERIODONTAL-DENTAL TRAUMA, TEMPORARY TEETH, PREVALENCE, ETIOLOGY.

Oral and facial traumatic pathology in children is a complex issue with a great impact on cervico-facial and psycho-somatic harmony, its epidemiological, clinical, therapeutic and developmental features differing from traumatic injuries in adults.

Data in the literature on the prevalence of periodontal dental trauma vary considerably from study to study. This large variability could be accounted for by a combination of factors such as trauma classification, type of studied dentition, or differences in geographical area, socio-cultural, and behavioral patterns of the studied groups (1).

In recent years there has been a considerable increase in the number of temporary teeth injuries, this variability being determined by multiple etiologic and predisposing factors which we need to be aware of

and that require preventive, curative and interceptive measures (1).

This paper aims to determine the epidemiological profile, etiology and specific lesions of dental periodontal traumas in a preschool population of Iasi County.

MATERIAL AND METHODS

The study group included a total of 672 subjects selected of the 729 targeted children aged 3 to 7 years old, from urban and rural areas of Iasi County, who have been examined in the Iasi Pediatric Dentistry Clinic between May, 2011- May, 2012.

Children were examined by specialist dentists who have previously participated in a calibration process to minimize potential inaccuracies of diagnosis and classification of traumatic lesions; thus, the classification proposed by Andreasen et al. (1) has been used.

Children legal guardians were informed about this research through oral presentations by the research team. All legal guardians were asked to fill-in a questionnaire including demographic data, circumstances of injury, and provided an agreement to enroll their child/children in the research. Also, a written informed consent was obtained.

Criteria for inclusion in the study were: age (3 to 7 years), obtaining informed consent from parents or legal guardians, absence of severe anterior teeth caries. Exclusion criteria were: refusal to provide informed consent, lack of child cooperation, eruption of permanent incisors.

The approval of the Ethics Committee of the "Grigore T. Popa" University of Medicine and Pharmacy - Iasi and Iasi School Inspectorate were as obtained.

For statistical data processing we used *STATISTICA* software. Specific tests (ANOVA, Pearson Chi - square (χ^2), Spearman, Gamma) were used and the parameters of interest were analyzed. Thus **p**, the calculated reference indicator, reflected the level of significance of the tests, was compared with p = 0.05 corresponding to a 95% confidence interval (CI) with a significant value for p <0. 05.

RESULTS

Prevalence of periodontal dental trauma in the study group was 19.64%.

Sex distribution of our patients was homogeneous (52.53% boys, 47.47% girls). When analyzing the sex distribution of injured children, a predominance of boys (62.12%) was found. This is supported by the nonparametric correlation Chi-square test, which indicates a moderate association between boys and presence of trauma ($\chi 2$ = 6.06, r = -0.438 p = 0.0137, 95% CI).

The risk for dental periodontal trauma in deciduous teeth for boys was 1.63 times higher than for girls (Odds Ratio = 1.63, minimum = 1.08, maximum = 2.45, 95 % CI). Prospectively, by calculating hazard ratio (the relative risk (RR)), it came out that boys have a 1.48 times higher risk of periodontal dental trauma (RR = 1.48, minimum = 1.08, maximum = 2.04, 95% CI). The rural/urban distributions of children with dental trauma revealed a higher prevalence (61.36%) of traumas in urban areas, and a moderate statistical association between the two parameters (tab. I).

Risk of periodontal dental trauma in urban children (calculated by contingency table) was significantly higher than in rural children. The calculated odds ratio was 2.12 (minimum = 1.41, maximum = 3.20, 95% CI) and the risk ratio (RR) was estimated at 1.83 (minimum = 1.34, maximum = 2.51, 95% CI).

TABLE I

Parameters estimated in testing the association of periodontal dental trauma in temporary teeth *vs.* area of origin

df=1	Chi-square χ^2	P *95% Confidence Interval*
Pearson Chi-square - χ^2	14.73144	0.00012
M-L Chi-square	14.75281	0.00012
Correlation Coefficient (Gamma)	-0.359902	0.00012

As to the etiology of periodontal dental trauma in temporary teeth in our study group, fall accidents (41.67%) ranked first, closely followed by playground accidents (31.82%).

Dental lesion profile in our patients was dominated by subluxations (26.52%), enamel fracture and intrusion, identified in 23.48% and 18.18% of cases, respectively. In significantly lower percentages other types of lesions were recorded: enamel and dentin fracture (9.09%), contusion (8.33%), lateral luxation (6.82%), penetrating fracture (4.55%) and avulsion (3.03%).

The mean age of injured children was 53.4 months ± 11.13 DS.

The relationship between dental-periodontal injury pattern correlation and mean age of children reflected a correlation of dental avulsions with the highest mean age (65.50 ± 12.56 DS), and of the penetrating fractures with the lowest mean age (42.67 ± 7.42 DS)) (tab. II).

TABLE II

Age-related indicators for the type of periodontal dental trauma in temporary teeth

Type of trauma	Mean age (months)	Mean		Std. Dev.*	Std. Er.†	Min‡	Max$^{\alpha}$	Q25$^{\beta}$	Median	Q75
		-95%	*-95%*							
Enamel fracture	55.00	51.04	58.96	10.80	1.94	36.00	65.00	49.00	62.00	63.00

*Standard Deviation; †Standard Error; ‡Minimum; $^{\alpha}$Maximum; $^{\beta}$Quartiles.

The analysis of lesional types according to the cause of trauma revealed that playground accidents mostly resulted in enamel fractures. Periodontal-dental trauma due to falls has most frequent resulted in lateral luxation, complicated fractures and subluxations, while bicycle accidents in intrusions and avulsions (fig. 1).

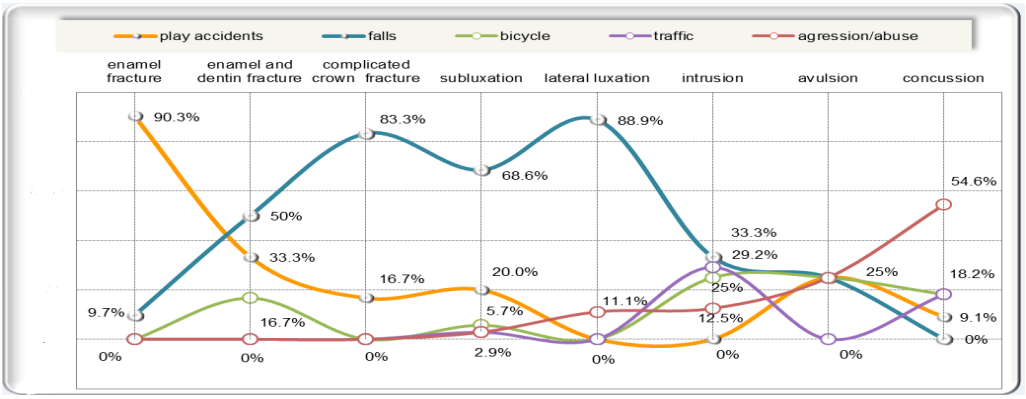

Fig.1. Temporary teeth dental-periodontal trauma etiology vs. type of injury

DISCUSSION

The prevalence of temporary teeth periodontal-dental trauma varies greatly in the literature. Thus, in Brazil (2, 3) it ranges between 9.4% and 41.6%, while in the US (4) it reaches 23.00% compared with 18% in Belgium (5). It should however be noted that many of these studies report the prevalence of different age groups (1), from preschool environments, both public and private, with or without socioeconomic differences, so they are unlikely to be comparable. As mentioned, this study was conducted on a age-limit population, and the traumatic events occurring before the age of 3 years, when there is an increased risk of dental injuries, were not recorded.

The 19.64% prevalence of traumatic injuries in temporary dentition found in our study group is close to that reported by Carvalho (5). This value can be close to the real one, but our study group being a small one it may not be representative for the entire pediatric population in the area of interest.

Although recent studies (4, 6) show that the distribution of periodontal dental trauma in temporary dentition is less influenced by sex, some authors (7) report that there is a higher frequency of occurrence in boys, as supported by the present research, which revealed a moderate association between trauma and boys.

The main etiological factor of periodontal-dental traumatic accidents in our study was falls, as found in most studies (5, 8, 9). Especially in younger age groups, poor motor coordination, specific curiosity and carelessness, may make children to perform tasks at high risk of trauma.

Data of various studies on periodontal dental injuries are difficult to compare due to the different classification criteria found in the literature; nevertheless, coronal fractures, simple or penetrating, are often reported as lesions with the highest prevalence by many authors (10, 11, 12). On the other hand, there are a significant number of studies which concluded that dental

luxation proved to be the most common type of injuries seen in primary dentition (13, 14). In our study subluxations and enamel fractures are the most common injuries. These differences can be accounted for by variations in study group selection, screening method, and researchers.

CONCLUSIONS

Prevalence of temporary teeth periodontal – dental trauma in our study group was relatively high (19.64%), requiring the implementation of strategies aimed at promoting oral health and prevention programs for parents and educators. To establish a more accurate profile of pediatric periodontal-dental trauma in our region and for their correct management, all medical and social institutions of interest in the field should become involved.

SÜDECK´S POST-TRAUMATIC OSTEODYSTROPHY

SÜDECK´S POST-TRAUMATIC OSTEODYSTROPHY (Abstract): The diversity that exists in the types of trauma, in the investigated anatomical structures, in the sites of trauma, in the outcomes of traumatic injuries, and in the general reaction of the body lead to a symptomatological polymorphism of post-traumatic sequelae. Therefore it is impossible to establish a well-defined nosological entity of these sequelae. The damaged tissues react under a very similar scheme, irrespective of the type of tissue, trauma or area, namely, through an inflammatory process, that causes various sequelae depending on certain parameters. Südeck post-traumatic osteodystrophy may be defined as a pathological entity based on some well-defined clinical features, on the development of its own therapy and on its more or less ubiquitous character. Südeck`s post-traumatic osteodystrophy of the hand is rarely found isolated. This "acute bone atrophy" is usually included in the "pathological syndrome of the hand" and is caused by circulatory disorders that occur on a traumatized hand or on a hand with injury "at a distance", especially when nerve damage is involved. **Keywords**: ALGONEURODYSTROPHY, POST-TRAUMATIC SEQUELAE, REFLEX SYMPATHETIC DYSTROPHY.

Vandenabelle (1) gave in 1976 an historical overview of algoneurodystrophy (AND) including description, outcomes and the names under which this disease was known: post-traumatic osteoarthropathy, acute bone atrophy, post-traumatic painful osteoporosis, reflex sympathetic dystrophy, neurotrophic rheumatism, shoulder-hand syndrome, Südeck-Leriche syndrome, neurotrophic syndrome, sympathetic algodystrophy of the limbs). Etiopathogenic and pathophysiological mechanisms were also chronologically reviewed.

Algoneurodystrophy is a form of disease that has a great variety of clinical aspects (2). That is why there are many controversies surrounding the different issues that define its nosological relations. One of them is “the acute inflammatory bone atrophy” (1900, Südeck) (3), which was seen as a clinically well-defined post-traumatic sequel. The anatomical substrate is the osteoporosis, that was called "acute inflammatory bone atrophy" by Südeck and was seen as a clinically well-defined post-traumatic sequela, but Südeck considered actually the inflammatory process as dominant.

The first relatively complete anatomoclinical description of algoneurodystrophy is attributed to Südeck (1900). The term “anatomical substrate” was used

for the first time by Südeck and this was the premise for describing the radiological changes. The anatomical substrate is the osteoporosis that was called "acute inflammatory bone atrophy" by Südeck and was seen as a clinically well-defined post-traumatic sequela.

This disease was later called "post-traumatic painful osteoporosis" by Leriche (3). He considered it as a local disturbance of the neurovegetative system and, as the sympathetic nervous system plays a main role, it was also called "reflex sympathetic dystrophy" in the Anglo-Saxon speaking world. The disease was later known as Südeck-Leriche syndrome (3).

Some neurotrophic disturbances may occur at the level of the hand after the injuries of this segment, as well as after the injuries "at a distance" of the upper limb (4).

These disturbances are not consistent with the severity of the primary traumatic lesions, but rather with the subsequent complaints experienced by the injured person, with the excitability of his nervous system, with the administered treatment and with the poor outcome of treatment of lesions.

Definition of Südeck´s post-traumatic osteodystrophy. Osteodystrophy is a generalized disease of the skeleton, characterized by decreased bone mass and deteriorated micro-architecture of the bone tissue. Osteoporosis leads to increased bone fragility and risk of fractures that may occur in minor trauma or even spontaneously. Osteoporosis is the most frequent metabolic bone disease and affects women more than men. It decreases the bone strength, which brings a greater risk of fractures. The major issue in the management of osteoporosis lies in the prophylaxis of this disorder, and the most economically advantageous and the easiest to apply method in the pacient self-care is the kinetotherapy prophylaxis.

Pathophysiological syndrome of the hand. The disorders of this syndrome may be designated as "syndrome of post-traumatic nervous irritation" or as "post-traumatic reactive syndrome"(5).

These post-traumatic trophoneurotic disturbances of the upper limb and of the hand in particular represent a disputed issue, both in terms of etiopathogenesis and treatment. The trophic disturbances have a progressive onset, from fingers to shoulder, when the lesion is distal, and from top to bottom, when the lesion is situated at distance from hand. No tissue is spared and there are to be seen alterations of the structure of skin, hair, nails, subcutaneous cellular tissue, aponeuroses, muscles and bones. The affected hand does not look like a normal hand anymore (6).

In milder cases, the tissue alterations suggest a simple atrophy caused by inactivity. In other cases, the extent of tissue alterations, the rapidity of their development, the associated vasomotor and motor disturbances, as well as the unusually high degree of function loss are due to the dynamic processes.

The pathophysiological syndrome of the hand may take various forms, depending on its intensity: from the simple atrophy caused by inactivity to the complex forms, associated with acute pain. The nervous mechanism that acts on the veins, capillaries, arteries and arterioles, causing nutritional disturbances in all tissues of distal segment of the upper limb, triggers also most of the alterations. Once this mechanism has been activated, it usually maintains a hyperemia with venous stasis, that

deeply disturbs the trophicity of the tissues as it becomes chronic.

The physiopathic syndrome of the hand is always associated with severe forms of Südeck`s osteoporosis. Most often the symptoms of these syndromes overlap and may be confounded: persistent pain that is exaggerated as compared to intensity of trauma, loss of hand function, edema and atrophy of subcutaneous cellular tissue, trophic disturbances of the skin, severe bone demineralization.

The topography of pain and of hyperesthesia does not correspond to the territory of any somatic nerve, as it is less localized and it is unbearable "as a visceral pain". The lesions of arteries or the injuries of the median nerve predispose frequently to nerve irritation syndrome; on the other hand, the median nerve has a much larger number of fibers that travel to the blood vessels as compared to the radial or the cubital nerve.

The centrifugal impulses that origin in the central nervous system and travel to the muscles, sudoriferous glands and blood vessels, as well as those that control vital activities of tissue cells are continuously dependent on the centripetal impulses coming from periphery. If these afferent messages are normal, then the efferent impulses are also normal. But if the afferent messages develop a harmful intensity and cause a permanent irritation, they disrupt the harmony of this automatic regulation, and the efferent impulses become also pathological and generate various disturbances (motor and vasomotor disturbances).

The cortex plays an important role in all these neurovascular disorders. In persons with labile nervous system, the nociceptive stimuli that come from the site of trauma through exteroceptors and proprioceptors act employing the cortex on the neurovascular system of the upper limb and of the hand in particular. This system is disturbed for a more or less long period of time, but sometimes it is chronically disturbed.

Any trauma, no matter how mild it may be, generates an irritative focus, that acts on the surrounding proprioceptors, that are very well developed at the level of fingers and in hand joints. The impulses that come from these areas and travel to the cerebral cortex generate changes in brain dynamics. If the signals that originate in the proprioceptors coincide in time with the excitations of the exteroceptors, conditioned reflexes can be produced. These conditioned reflexes may be sometimes fixed and lasting and may exert multiple effects on the function and trophicity of the tissues.

Clinical aspects. The symptomatology shows three clinical stages of evolution. Stage 1 emerges immediately or sometimes within a few weeks after the injury. It is characterized by acute pain, that increases with movement, skin hyperemia (the skin is warmer and more moist than normal), muscular hypotonia, edema of skin, of connective tissue and of muscle, early osteoporosis (7). Stage 2 develops in the next three months. The pain persists, the skin is cyanotic, cold, moist, and the hair in the area breaks off or gets lost. The edemas persist, joint stiffness occurs and the radiographic diagnosis is represented by the characteristic spotted osteoporosis. Stage 3 is generally regarded as irreversible and it is characterized by atrophic processes of skin, muscles, by having aponeurotic retraction and tendon retraction, severe osteoporosis (in some cases marked bone resorption), functional impotence of joints. At this stage the pain is

decreased, but it disseminates to the limb root. The skin becomes dry and cold.

Hyperemia may explain the osteoporosis, the edema of soft tissues, but it cannot fully motivate the pain, the atrophy and the sclerosis.

Thus, the syndrome is clinically characterized by hyperemia and cyanosis of the skin, that are usually associated with subcutaneous edema and with impairment of finger movements. The joint stiffness and the muscle atrophy also occur. The persistence of pain, the hard edem, the atrophy of subcutaneous tissue and of muscles, the thickening of the joint capsule, the deformation of the fingers in flexion, the progression of osteoporosis may also indicate this syndrome.

The evolution shows various forms of onset. *Acute onset* – in full health, weeks and rarely months after a traumatic episode or after an organic disorder, an algoneurodystrophic syndrome and its characteristic symptoms develop in 24 hours or in 30 days at most. In the cases with acute onset, the local symptoms are very intense and the general repercussion on the body is significant. *Subacute onset* – is the most common form. In 6-7 days the painful and vasomotor syndrome occurs. The local and general symptoms are less obvious than in the acute dramatic form of the acute onset. *Chronic onset* – is found usually at an older age, in neurological patients and in less reactive persons. In 15 days at most a painful and vasomotor syndrome gradually emerges, but it is frequently attenuated and therefore difficult to diagnose (8).

Diagnosis. The inflammation tests are negative and ESR may have values of 30 mm /h. The radiography reveals a local demineralization and shows a spotted osteoporosis of spongiosa. The compact bone of the diaphyses is spared for some time, but then it also become thin. Nevertheless joint space narrowing or cartilage thinning are not found.

The bone scintigraphy shows characteristic uniform uptake. If the traumatic lesions are peripheral (fingers), the atrophy progresses in a centripetal direction. If the lesions are "at distance" from hand (e.g. lesions of the nervous trunks), the bone atrophy progresses in a centrifugal direction, towards the periphery of the upper limb.

Osteoporosis occurs in closed or open mechanical trauma, in burns, frostbites, nerve damage and especially in the latent inflammations that follow these injuries.

The histopathological examination shows a discrete synovial and subsynovial edema. There are also perivascular cellular infiltrations with lymphocyte predominance.

The treatment is developed with regard to the triggering event, to the severity of trauma, to the stage of disease and to the prophylaxis.

If the syndrome begins to develop, the treatment involves the suppressing of all irritations that originate in the traumatic focus, balancing the nervous system, recovering the normal activity of the hand (active kinetotherapy).

The suppression of irritations is made by complementing the surgery of traumatic focuses and of their complications, namely, unreduced fractures, non-eliminated sequestra, irritating foreign bodies, painful nerve injuries, subacute infections, etc.

One of the best means of suppressing irritations of the traumatic focuses is the proper immobilization of the injured segment (immobilization depending on posi-

tion The balancing of the nervous system is also important and it is achieved by gaining patient`s confidence and by obtaining the patient`s full compliance to treatment, as well as through novocaine infiltrations at various levels, especially on the upper thoracic ganglia.

The somatic nerve infiltrations have a good outcome. They may be performed at distance from hand, on the nervous trunks or even on the brachial plexus or they may be locally applied, around the lesion, in the area of hyperesthesia. Thus, they act for the suppression of the nociceptive irritations. Local infiltrations with novocaine have a better outcome when the point from where the afferent nociceptive stimuli originate is precisely identified and injected. The infiltrations on the regional sympathetic nervous system act on the afferent pathways.

The recovery of the normal activity of hand (when possible) leads to healing in the shortest possible time. All procedures should be always performed carefully, skillfully and with full compliance of the patient, in order to achieve simultaneously the immobilization needed for the suppression of the irritations of the traumatic focus and the active mobilization of the uninjured segments. This mobilization should be performed carefully and persistently, progressively, as the movements must always be made below the threshold of pain.

The concomitant upper extremity suspension that reduces the venous stasis and edema, contributes to the implementation of the active kinetotherapy.

The edema of the back of the hand may represent one of the components of the physiopathic syndrome, especially when this edema becomes chronic as in hard edemas. However, the chronic edema of the back of the hand may also occur isolated, without the other components of the syndrome or without having components so marked as the edema. The edema requires surgery when it becomes chronic and hard.

Curative treatment – has the following aims: to eliminate pain, to intercept the pathogenic line, to recover the function of the affected segment. Combining drug therapy with kinetotherapy and with orthopedic surgery may result in cutting off the reflex circle, the restoring of a normal active vascularization and not least the pain relief.

The therapeutic means that pursue the specific blockade of the sympathetic nervous system represent the most reasonable strategy. This blockade alleviates pain, because the pain impulses that are produced as a reflex in the somatic C-fibers by the excitation of the adjacent sympathetic postganglionic fibers disappear. Thus, the pathological afferentation towards the intercalary neurons is interrupted (or reduced) and results in the reduced activity of these neurons. But the blockade does not completely eliminate pain, because the pain impulses continue to be triggered from the hyperemia area of the affected joints and they travel through the common thick somatic fibers towards the spinothalamic pathway.

Vasodilators are frequently used. Calcitonin reduces bone resorption, decreases the activity and the number of osteoclasts, but they do not repair what has been lost. It also decreases rapidly the pseudo-inflammatory phenomena and it has an analgesic effect through a double mechanism (peripheral and central). Calcium preparations, synthetic anabolic substances and psychotropic drugs may also be used.

The kinetotherapy treatment aims to

restore joint mobility and the muscle tone and represents the mainstay of recovery, but when associated with physiotherapy can give in some cases even better results (1, 10). Through the used methods and procedures, kinetotherapy plays a very important role both in primary and in secondary prevention, as the use of a specially structured and assembled physical exercise has a beneficial effect on disease prevention, as well as on prevention of deficiencies and dysmorphisms caused by sequelae of medical conditions or injuries (9).

Südeck and Böhler (cit. 10) suggested that this syndrome may be prevented if the nociceptive stimuli are suppressed. Although bone atrophy is thought to be "inevitable" in risk populations, the complete syndrome develops only if the rules of proper immobilization of the traumatic focus are not followed. This immobilization should be associated with the active mobilization of all uninjured segments. "No mobilization exercise should cause pain", because the pain is the most important nociceptive stimulus in such cases. This stimulus leads to neurovascular disturbances that maintain or aggravate Südeck`s syndrome. If the syndrome is installed (at the stage of spotted atrophy of spongiosa), the safest means of stopping its development is the proper immobilization itself, namely, uninterrupted, in the passive posture of the affected segment, with the active, careful mobilization of the mobilized segments, as long as the pain does not arise (11).

In order to combat the venous stasis and the edema, the suspension of the upper limb or at least of the hand can be simultaneously used. The following physiotherapeutic measures may also be recommended for accelerating the healing: short warm baths (for 10 minutes) followed by the suspension of the upper limb, circulatory gymnastics through warm baths alternating with cold baths, cold air baths (for 15-20 minutes), and diathermy may also have beneficial effects (12).

In bone atrophies with finger stiffness, the perseverance of kinetotherapists and the full and conscious compliance of the patient may result in the partial recovery of finger motility (13).

**Prognosis of Südeck`s syndrome.** The post-traumatic Südeck`s syndrome has usually a favorable prognosis, as the acute bone atrophy disappears progressively after the suppression of irritative noxae.

If the bone atrophy persists as a result of maintain the continuous irritations, it may become chronic and a marked osteoporosis of the whole upper limb develops. These bones have a "glassy" appearance.

The acute "spotted" atrophy may develop into chronic bone atrophy if the primary lesion and the irritations that arise from it are not managed in time.

The evolution of the disease is unpredictable, and remains unpredictable even when a complex pathogenic treatment is administered. Many forms that were treated with complex therapies evolve arbitrarily, and the vasomotor and painful symptoms may return after they have regressed as a result of the treatment (14, 15, 16).

CONCLUSIONS

The best management of Südeck`s disease is represented by the consideration for improving of the kinetotherapeutic strategies, for pain relief, for reducing vascular stasis, for avoiding contractures and capsular retractions, as well as for combating anxiety and depressive moods in patients.

By means of an educational therapeutic rehabilitating process, kinetotherapy aims to improve the physical and mental health of persons with special health needs, in order to facilitate them the social and occupational integration or reintegration.

HUMAN PAPILLOMA VIRUS INFECTION AND CERVICAL DYSPLASIA (Abstract): Pap testing is considered to be the best screening tool for cervical cancer but there is currently great interest in the possible application of Human Papilloma virus (HPV) testing to supplement Pap screening for cervical cancer. **Aim:** To determine the prevalence of high-risk HPV types in the studied population and to explore the association between high-risk HPV types and cervical dysplasia. **Material and methods**: Cross-sectional study conducted at the Iasi "Cuza Voda" Obstetrics-Gynecology Hospital and Suceava County Hospital. 332 women who underwent colposcopy for cervical lesions between 2006 and 2011 were included in this study. **Results**: The overall prevalence of HPV was 57.23%. HPV prevalence differs significantly in the three age groups up to 50 years. It was highest in patients below the age of 40 and progressively lower with advancing age. The overall prevalence of cervical dysplasia was 56.62%. The prevalence of cervical dysplasia was highest in the age groups up to 40 years. The most important determinant of HPV infection is age. **Conclusions**: Persistence of HPV appears to be associated with progression to squamous intraepithelial lesion. Dysplasia is often missed in a cervical sample either because of human error in screening and interpretation, or because of suboptimal quality of Pap smear. Incorporation of HPV testing into the present Pap screening program has the potential of making screening for cervical cancer more effective, and a necessary prelude to assessing this is by determining the prevalence of the high-risk types. **Key words:** INVASIVE CERVICAL CANCER, PAP TEST, HUMAN PAPILLOMA VIRUS

Invasive cervical cancer is a disease that can be prevented by early detection and treatment. Recognizable precursor lesions generally precede it. The introduction of Pap screening programs has accelerated the decline in mortality due to cervical cancer in the past 45 years. Although this indicates a successful screening program, a series of studies revealed the sensitivity of the Pap smear to be only 51% and an unacceptable number of women who have been cytological screened develop invasive cervical cancer.

The objectives of the study were to determine the prevalence of high-risk HPV types and of cervical dysplasia in the studied population and to explore the association between high-risk HPV types and cervical dysplasia.

MATERIAL AND METHODS

In order to achieve these objectives, a cross-sectional study was conducted at the Iasi "Cuza Voda" Obstetrics-Gynecology Hospital and Suceava County Hospital. 332 women who underwent colposcopy for cer-

vical lesions between 2006 and 2011 were invited to participate. Written informed consent was obtained from the women being screened. Subjects were assured that their participation was voluntary and that their regular medical care would not be affected if they declined to participate.

The procedure for sample collection for HPV testing was incorporated into routine Pap testing. Pap samples were collected in a liquid based medium, which allowed both cytological diagnosis and HPV testing to be done on the same sample.

A cervical broom device was used to collect cells from the endocervix. The brush was then swirled immediately into a 20-ml container of buffered fixative to dislodge the cells into the medium. The sample was transported to the cytology laboratory of the Synevo laboratories in Romania. Pap test was always done first. Residual samples were forwarded for HPV testing. Pap smear reporting was based on the Bethesda System and the results were forwarded to the researcher. Cytology results were classified as follows: negative, benign cellular changes (BCC), atypical squamous cells of undetermined significance (ASCUS), low grade cervical squamous intraepithelial lesion (LSIL) and high grade cervical squamous intraepithelial lesion (HSIL). A pathologist routinely reviewed all abnormal Pap smears.

Colposcopy with cervical biopsy was performed in all cases. The findings of cervical biopsy histopathology were defined as HSIL, LSIL, negative (no colposcopic abnormality), others (including condyloma, benign atypia, HPV changes, squamous intraepithelial lesion unqualified, squamous intraepithelial lesion unqualified favoring HSIL or LSIL, immature squamous metaplasia with or without atypical, mature squamous epithelium, acute and chronic inflammation), adenocarcinoma in situ (AIS), and invasive cervical cancer.

Confidence intervals (the least frequency with which the interval will contain the true parameter) do much more than assess the extent to which the null hypothesis is compatible with the data. They provide simultaneously an idea of the likely magnitude of the effect and random variability. In this study 95% confidence intervals were used to assess statistical significance and random variability of the point estimate. Confidence intervals can also show that the data do not contain the information necessary for reassurance about an absence of effect. For a study to provide evidence of lack of an effect, the confidence limits must be near the null value. P-values were reported when analysis of trends were done.

RESULTS

Data on patients'age and educational level were obtained from laboratory requisition form and clinical documentation. Mean age of patients was 36.9 ± 11.57 years with a median of 28 years. Most of the patients (176 – 53.01%) followed a medium education (high school). Age-group prevalence of HPV infection is presented in tab. I.

TABLE I

Age-group prevalence of HPV infection

Age group	Number of subjects	HPV prevalence	95% CI
<30	106 (31.93%)	58.49%	42.6-65.8
31-40	146 (43.97%)	59.59%	52.5-68.6
41-50	50 (15.06%)	54%	50.5-57.9
>51	30 (9.04%)	56.66%	48.9-60.0

HPV prevalence differs significantly in the three age groups up to 50 years. It was highest in the patients under 40 and progressively lower with advancing age.

HPV prevalence did not differ signifi-

cantly with education. Sixty-four patients (19.69%) did not provide information on their education level and prevalence in this group was about the same as for those with known education.

HSIL accounted for 88 (26.5%), LSIL for 92 (27.71%), atypical squamous cells of undetermined significance (ASC-US) for 69 (20.78%) and squamous cell carcinoma (SCC) for 5 (1.5%) of the referral Pap smears in women with cervical dysplasia. Pap smear was negative in 78 cases (23.49%).

Colposcopically directed cervical biopsies reported no pathological abnormality (negative) in 64 (19.28%), HSIL in 105 (31.62%), LSIL in 83 (25%) and other lesions in 80 (24.1%) women. A fair agreement between Pap smear and cervical biopsy was proved by the Kappa test (0.5) when analyzing for squamous intraepithelial lesions (SIL).

The prevalence of cervical dysplasia was highest in the age groups up to 40 years. At age >41, the prevalence was half of that at the younger ages, and dropped even lower among those over 50.

Although not statistically different, prevalence of cervical dysplasia was slightly higher among those with high school education than in those with no or primary education, and higher again among those with a higher education.

In women with the cytological diagnosis of SIL, over 90% had HPV. Twenty-one percent of the women who were negative for cervical dysplasia (including BCC) were positive for HPV.

Women younger than 40 years had the highest odds ratio (OR) for HPV infection. The OR was significantly lower (0.63) in the 41-50 year-old group and dropped even lower (0.22) in those over the age of 51.

When comparing the OR for HPV infection in the groups by education, the lowest association (fully adjusted) was for the group with high school education, while the strongest association was in those with no, primary or gymnasium education had. Those with unknown education had the same OR as those with secondary education.

TABLE II

Odds ratio (OR) and 95% confidence intervals (95% CI) for cervical dysplasia and age, adjusting for the other variables and then additionally adjusting for HPV

Age group	Basal OR	Basal 95% CI	Fully adjusted OR	Fully adjusted 95% CI	HPV adjusted OR	HPV adjusted 95% CI
<30	1.0	Referent	1.0	Referent	1.0	Referent
31-40	1.02	0.6-1.7	1.03	0.6-1.7	1.5	0.8-2.7
41-50	0.45	0.2-0.9	0.43	0.2-0.9	1.3	0.6-2.8
>51	0.33	0.1-0.7	0.32	0.1-0.8	0.66	0.3-2.2

HPV was very strongly associated with cervical dysplasia (OR: 28.6) even after adjustment for age, education and smoking status. Even though the confidence intervals were large (95% CI: 12-76), it was evident that HPV was significantly associated with cervical dysplasia.

Women aged 40 and younger had the highest OR for cervical dysplasia and it was less than half in the women over 41. With age, OR became insignificant in the fully adjusted model and in fact it was HPV that mostly influenced this change.

There seemed to be a pattern of decreasing OR estimates for cervical dysplasia in smokers, with those who were former

smokers having a lower OR (0.70) and current smokers having an even lesser OR (0.62); however, none of these were statistically significant.

The age-adjusted odds of having cervical dysplasia increased significantly and dramatically with increasing viral load. The p-value for this trend is <0.0001. The prevalence of high-risk HPV types was about 55% and did not differ significantly by level of education. However, it did differ significantly by age showing a dramatic decrease in prevalence from 62.1 % in the less than 40 year-olds to 48% in the over 41 year-old.

Prevalence of cervical dysplasia was 56.62% and did not differ significantly by highest level of education in the household. It too differed significantly by age between under 40 (59.7%) and over 41 year-olds (53.9%). Over 90% of women with a cytological diagnosis of SIL had high-risk HPV types.

Basal and age adjusted OR's between HPV and the five selected variables showed age as the only variable significantly associated with HPV. Age was also significantly associated with cervical dysplasia but the OR estimates shifted toward the null when controlling for HPV and the association changed to become insignificant after that adjustment HPV was strongly associated with cervical dysplasia with a fully adjusted OR of 28.6 (14.7, 55.5). The association between cervical dysplasia increased markedly with increasing viral load ($p<0.0001$).

DISCUSSION

Cervical dysplasia is a broad term describing the precursor lesions that are considered to be indicators of the progression to cervical cancer. These lesions were classified as cervical intra-epithelial neoplasia (CIN).

Numerous studies have consistently reported the association between sexual behavior and cervical cancer, and since the 1980's, attempts have been made to try to understand the role of HPV as the sexually transmitted agent responsible. The poor sensitivity and specificity of the methods used for HPV testing have led to varying estimates of the relationship between HPV infection and cervical neoplasia and this variability had led to considerable skepticism about the clinical role of HPV. A new generation of HPV testing has shown more consistent associations, and HPV DNA has been detected in over 99.7% of tumors from patients with invasive cervical cancer. HPV - negative cancers are virtually non-existent (5, 6).

This study found a strong association (OR: 28) between high-risk HPV types and cervical dysplasia. Comparison with other studies has been difficult because of the different techniques used for detection and the different combinations of strains being tested for, nonetheless, OR's of over 15 have been reported in a review of case-control studies that used reliable methods for HPV DNA detection. Cigarette smoking has been described as an independent risk factor for cervical neoplasia however this was not evident in this study. The OR estimates were actually lower in smokers but these were not statistically significant.

In examining indicators of socio-economic status, one study used low educational achievement and found it associated with increased odds ratios (OR's) of 3.4 (1.2-10.1) for CIN. Bosch et al also found a low level of education to be associated with cervical cancer (1).

The role of smoking is controversial. Some studies have shown a significant association between smoking and invasive cervical cancer; however, there has been uncertainty about whether the reported association

was a causal or a confounding phenomenon reflecting such factors as sexual habits and infection with an unidentified infectious sexually transmitted agent (7).

Other risk factors that have been examined in the literature are oral and barrier contraceptives. Studies on oral contraceptives have shown protective, null, or weak associations with cervical neoplasia. Most recent studies have shown no association with barrier contraceptives have been shown to have a protective effect against cervical cancer: vaginal spermicides (OR = 0.28), diaphragms (OR = 0.67) and condoms (OR = 0.53) (8).

A series of studies have revealed that a unique feature of HPV testing is the ability to predict the subsequent development of cervical cancer precursors among cytologically negative women (9).

CONCLUSIONS

Persistence of HPV appears to be associated with progression to SIL. The high rates of sexually transmitted diseases (STD) imply that a potentially large number of women in Romania are at high risk for development of cervical cancer. Early detection could mean earlier treatment and a reduction of the number of women at risk for progression to invasive cancer.

Among patients with an abnormal Pap smear, women with HSIL require immediate colposcopy and histologic diagnosis. For patients with ASCUS or LSIL, women can be followed by either performing colposcopy immediately or by repeating the smears every six months for two years, or then performing colposcopy if LSIL persists.

PREVALENCE OF HUMAN PAPILLOMA VIRUS ISOLATED FROM CERVIX LESIONS IN A FEMALE POPULATION FROM TRANSILVANIA (Abstract): Between the years 2008-2011 reverse hibridisation (INNO-LiPA HPV Genotyping Extra test) and genotyping la Roche (the kit: Linear array HPV genotyping test) were used for detection of Human Papilloma Virus (HPV) in the cervix secretions of 182 female patients aged 16-63 years, predominantly of urban origin. 99 patients (54.4%) were identified as being infected with various types of HPV, prevalent in urban (53 single infections and 46 multiple infections). HPV infection was not detected in 83 (45.6%) patients. Only 7 females from rural areas were tested (5 females had single or multiple HPV infections). 32 types of HPV were identificated: 15 HPV types with high risk (51, 82, 56, 18, 39, 45, 59, 68, 16, 31, 33, 35, 52, 58, 73), 14 types with low risk (42, 61, 62, 72, 81, 83, 84, CP6108, 70, 6, 11, 55, 74, 54), and 3 types with possible high risk (26, 53, 66). The type of HPV could not be identified in other two cases. The most frecvent types of HPV with high risk isolated were: the type 16. The types 51 and 58 of HPV with high risk and the type 84 with low risk are detected in single infections in urban and in rural. HPV clades involved in single infections are: 1 (1 case), 3 (5 cases), 5 (4 cases), 6 (5 cases), 7 (5 cases), 9 (21 cases), 10 (7 cases). The clades 11 (7 cases) and 13 (6 cases) were involved only in multiple infections detected in urban. The types 35, 39, 59, 68 of HPV with high risk were isolated from multple infections. In rural, multiple infections with two HPV were detected. The citological screening by Babeş-Papanicolaou examination was made only in 9 cases: HPV was not detected in 4 cases (one female had ASC-US: atypical squamous cells of "undetermined significance"); in 5 positive cases were detected HPV 16, 31, 58, 6. **Key words:** PCR, HPV, INFECTIONS, URBAN, RURAL, CITOLOGICAL EXAMINATION

Infecția cu HPV este considerată cea mai frecventă dintre infecțiile cu transmitere sexuală; se estimează că 75% dintre persoanele active sexual au fost infectate cu HPV la un moment dat în viață.

Cancerul colului uterin este a doua cauză frecventă de deces prin cancer la femei în întreaga lume. Epiteliul scuamos este cel

mai susceptibil la infecţia cu HPV. Este important să se stabilească prevalenţa infecţiei cu HPV în diferite tipuri de leziuni cervicale şi să se evidenţieze relaţia dintre HPV şi gravitatea leziunilor cervicale (1). Rolul HPV în patogeneză a fost recunoscut pentru mai multe tipuri. Unele virusuri, specifice pentru mucoasa genitală, în special HPV 6 şi 11 (tipuri benigne), pot infecta şi alte mucoase (respiratorie, bucală, conjunctivală) (2, 3). Astfel, HPV 16 este implicat în cancerele cervicale invazive (4). Sensibilitatea şi specificitatea screeningului pentru cancer cervical creşte prin combinarea citologiei şi a hibridizări (5). Genotiparea HPV permite o clasificare mai bună a femeilor cu anormalităţi cervicale în diferite grupe de risc şi poate fi utilă în orientarea tratamentului (6).

MATERIAL ŞI METODE

În perioada 2008-2011 au fost investigate secreţiile cervicale recoltate de la 182 de femei în vârstă de 16-63 de ani, provenind din mediul urban şi rural, în scopul depistarii virusurilor Papilloma umane **(**HPV), utilizând tehnica PCR:

1. Tehnica PCR de hibridizare inversă (testul INNO-LiPA HPV Genotyping *Extra*) (INNOGENETICS) a fost utilizată în anul 2008. Testul permite decelarea a 28 de genotipuri HPV (având 28 de sonde moleculare specifice şi 4 sonde de control): HPV cu risc crescut (High risk): 16, 18, 31, 33, 35, 39, 45, 51, 52, 56, 58, 59, 68, 73, 82; HPV cu risc probabil crescut (Probable high risk): 26, 53, 66; HPV cu risc scăzut (Low risk): 6, 11, 40, 43, 44, 54, 70; HPV neclasificate din punct de vedere al riscului oncogen (Additional types): 69, 71, 74 (7).

2. Tehnica PCR de genotipare Roche – kitul Linear array HPV genotyping test, folosind aparatul PCR–Golden Plated GeneAmp® PCR System 9700 de la Applied Biosystems, a fost utilizată în perioada 2010-2011. Această metodă poate detecta 37 de tipuri de HPV: 6, 11, 16, 18, 26, 31, 33, 35, 39, 40, 42, 45, 51, 52, 53, 54, 55, 56, 58, 59, 61, 62, 64, 66, 67, 68, 69, 70, 71, 72, 73, 81, 82, 83, 84, IS39, CP6108 (8).

Prelucrarea statistică a rezultatelor a apelat la compararea a două medii cu o distribuţie de probabilitate normală prin testul Student, iar în cazul în care nu a existat o distribuţie normală a fost utilizat testul Mann-Whitney. Pentru compararea a mai mult de două medii cu o distribuţie de probabilitate normală a fost utilizat testul Anova. În cazul în care nu a existat o distribuţie normală s-a utilizat testul Kruskal-Wallis. Pentru testarea distribuţiei normale a fost folosit testul Kolmogorov-Smirnov. Pentru compararea a două frecvenţe a fost utilizat testul hi-pătrat sau Fisher-exact în cazul în care frecvenţele teoretice sunt sub 5. Analiza de corelaţie între variabile continue a fost efectuată prin calcularea coeficienţilor de determinare şi ecuaţia dreptei de regresie. Pragul de semnificaţie pentru testele folosite a fost luat $\alpha = 0,05$. Calculele statistice au fost efectuate cu ajutorul aplicaţiilor *SPSS 13.0*.

REZULTATE

Din cele 182 de testări efectuate, în 99 de cazuri (54,4%) a fost detectat HPV (53 de cazuri: 53,5% - infecţii unice şi 46 de cazuri: 46,5% - infecţii multiple), fiind identificate 32 de tipuri diferite de HPV:

- 15 tipuri de HPV cu risc crescut (C) (HPV: 51, 82 (grup filogenetic α5), 56 (grup filogenetic α6), 18, 39, 45, 59, 68 (grup filogenetic α7), 16, 31, 33, 35, 52, 58 (grup filogenetic α9), 73 (grup filogenetic α11);
- 14 tipuri de HPV cu risc scăzut (S):

42 (grup filogenetic α1), 61, 62, 72, 81, 83, 84, CP6108 (grup filogenetic α3), 70 (grup filogenetic α7), 6, 11, 55, 74 (grup filogenetic α10), 54 (grup filogenetic α13);

- 3 tipuri de HPV cu risc probabil crescut (PC): HPV 26 (α5) şi 53, 66 (α6).

La alte 2 cazuri nu s-a putut preciza tipul de HPV (HPV X).

Examenul citologic Babeş-Papanicolaou a fost efectuat numai la 9 paciente. La un caz (femeie de 32 de ani) s-a evidenţiat ASC-US, atipii ale celulelor pavimentoase intermediare. La celelale 5 cazuri (4 din mediul urban şi 1 din mediul rural) s-a identificat prin PCR HPV de tip 16 în două cazuri (asociat cu ASC-US sau ASC-H) şi respectiv tipurile 31, 58 şi 6.

Din cele 182 de femei, în 83 de cazuri nu am găsit infecţie cu HPV, 53 de cazuri aveau infecţii unice, 26 de cazuri prezentau infecţie cu două tipuri de HPV şi la 20 de cazuri identificate in mediul urban am diagnosticat asocieri de 3, 4, 5 sau 6 HPV (fig. 1).

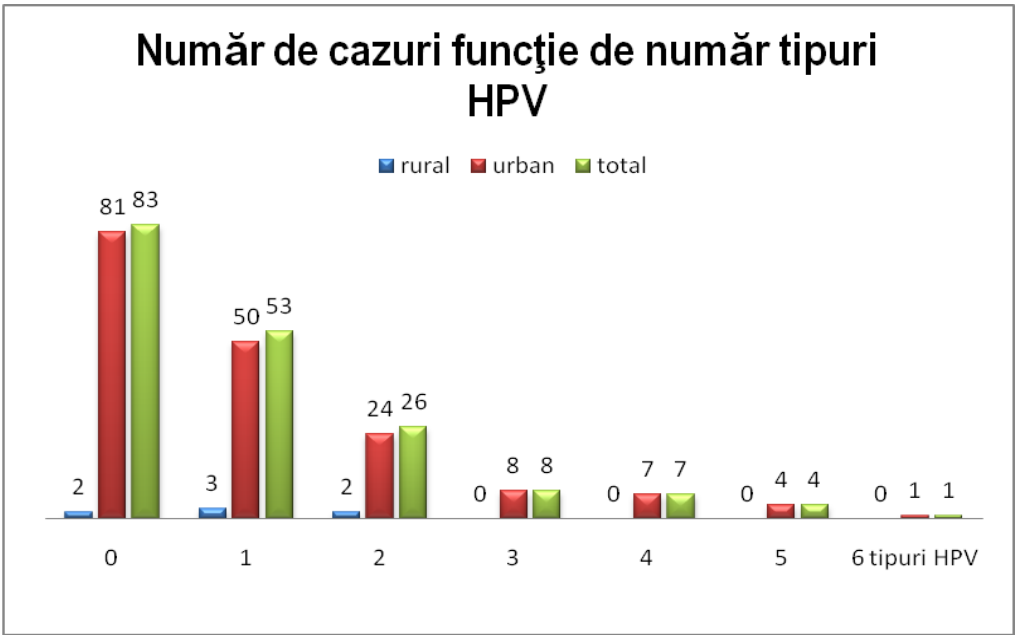

Fig. 1. Numărul de cazuri funcţie de numărul de tipuri de HPV

Din cele 99 de infecţii cu HPV, 94 de cazuri (94,9%%) au fost detectate *în mediul urban* şi dintre acestea *50* (53,2%) sunt *infecţii unice* (produse de un singur HPV) şi *44 (46,8%) infecţii multiple* (cauzate de mai multe tipuri de HPV).

Tipurile de HPV implicate în *infecţii unice în mediul urban* şi numărul total de cazuri detectate, mai ales la femei cu vârsta de 20-30 de ani sunt prezentate în tabelul I.

Tipurile de HPV 51, 58 cu risc crescut şi tipul 84 cu risc scăzut sunt implicate în infecţii unice atât în mediul urban cât şi în mediul rural.

În infecţiile multiple cu HPV detectate *în mediul urban* se pot asocia două, trei, patru, cinci, chiar şase virusuri (tab. II, III).

TABELUL I

Tipurile de HPV implicate în infecţii unice la femei în mediul urban

Tipuri de HPV	**Riscul HPV**	**Grup filogenetic**	**Număr total de cazuri**	**Număr de cazuri din total între 20-30 de ani**
16, 31, 33, 52, 58	C	α9	21	13 (6 cazuri cu tipul 16; 3 cazuri cu tipul 31; 1 caz cu tipul 33; 2 cazuri cu tipul 52; 1 caz cu tipul 58)
45, 18	C	α7	5	1 caz cu tipul 45 la 26 de ani; 1 caz cu tipul 70 la 20 de ani
70	S			
51, 82	C	α5	4	4 (tipul 51: 2 cazuri la 30 de ani, 1 caz la 21 de ani; tipul 82: 1 caz la 25 de ani)
56	C	α6	5	2 cazuri cu tipul 66 la 24 şi la 25 de ani
66	PC			
6, 55	S	α10	7	5 cazuri cu tipul 6 (cate 2 cazuri la 21 si 22 de ani; 1 caz la 23 de ani)
42	S	α1	1	-
62, 81, 83, 84, CP6108	S	α3	5	1 caz cu tipul 83 la 23 de ani
HPV X **(neprecizat)**	-	-	2	1 caz la 21 de ani

TABELUL II

Asocieri de câte două tipuri de HPV /număr de cazuri în mediul urban

Asocieri de câte două tipuri de HPV/număr de cazuri/vârstă						
16, 52 (α9/α9) 1 caz la 20 de ani	16, 54 (α9/α13) 1 caz la 44 de ani	16, 55 (α9/α10) 1 caz la 29 de ani	16, 39 (α9/α7) 1 caz la 27de ani	16, 35 (α9/α9) 1 caz la 32 de ani	16, 61 (α9/α3) 1 caz la 42 de ani	16, 6 (α9/α10) 1 caz la 21 de ani
6, 11 (α10/α10) 1 caz la 16 ani	6, 74 (α10/α10) 1 caz la 38 de ani	6, 35 (α10/α9) 1 caz la 25 de ani	6, 68 (α10/α7) 1 caz la 25 de ani	6, 31 (α10/α9) 1 caz la 22 de ani	6, 66 (α10/α6) 2 cazuri: la 22 şi 31 de ani	51, 82 (α5/α5) 1 caz la 33 de ani
66, 51 (α6/α5) 1 caz la 23 de ani	66, 83 (α6/α3) 1 caz la 23 de ani	62, 58 (α3/α9) 1 caz la 29 de ani	62, 73 (α3/α11) 1 caz la 20 de ani	52, 11 (α9/α10) 1 caz la 35 de ani	52, 31 (α9/α9) 1 caz la 29 de ani	52, 53 (α9/α6) 1 caz la 43 de ani
53, 70 (α6/α7) 1 caz la 44 de ani	54, CP6108 (α13/α3) 1 caz la 25 de ani					

În mediul rural, din cele 7 cazuri investigate, la 3 cazuri au fost detectate *infecţii unice* cu HPV tipul 51 cu risc crescut (C) la o pacientă de 39 de ani (1caz), HPV tipul 58 cu risc crescut la o pacientă de 63 de ani (1caz) şi HPV tipul 84 cu risc scăzut la o

pacientă de 24 de ani (1 caz). *În mediul rural, infecțiile multiple cu HPV* au fost produse numai de asocieri de două HPV: tipul 16 cu risc crescut şi tipul 61 cu risc scăzut (la o pacientă de 23 de ani), iar la o pacientă de 20 de ani – tipul 18 (risc crescut) şi CP 6108 (risc scăzut).

TABELUL III

Asocieri de 3, 4, 5 şi 6 HPV detectate în mediul urban

Asocieri de HPV	**Tipuri de HPV asociate/număr de cazuri/vârstă**						
Asocieri de 3 HPV	16, 51, 52 (α9/α5/α9)	58, 81, CP6108 (α9/α3/α3)	52, 59, 62 (α9/α7/α3)	51, 66, 52 (α5/α6/α9)	16, 53, 73 (α9/α6/α11)	55,72,73 (α10/α3/α11)	52, 53, 82 (α9/α6/α5)
	1 caz la 20 de ani	1 caz la 22 de ani	1 caz la 28 de ani	1 caz la 22 de ani	2 cazuri: la 25 şi 36 de ani	1 caz la 22 de ani	1 caz la 23 de ani
Asocieri de 4 HPV	53, 31, 52, 54 (α6/α9/ α9/α13)	53, 66, 16, 54 (α6/α6/ α9/α13)	39, 31, 52, 54 (α7/α9/ α9/α13)	45, 51, 52, 62 (α7/α5/ α9/α3)	42, 52, 55, 81 (α1/α9/ α10/α3)	16, 35, 56, 61 (α9/α9/ α6/α3)	31, 53, 62, 81 (α9/α6/ α3/α3)
	1 caz la 31 de ani	1 caz la 20 de ani	1 caz la 24 de ani	1 caz la 34 de ani	1 caz la 27 de ani	1 caz la 26 de ani	1 caz la 42 de ani
Asocieri de 5 HPV	6, 16, 54, 73, 84 (α10/α9/ α13/α11/α3)	6, 31, 35, 39, 73 (α10/α9/α9 /α7/α11)	11, 18, 31, 33, 61 (α10/α7/ α9/α9/α3)	33, 53, 73, 82,CP6108 (α9/α6/α11 /α5/α3)			
	1 caz la 19 ani	1 caz la 23 de ani	1 caz la 21 de ani	1 caz la 22 de ani			
Asociere de 6 HPV	16, 26, 39, 42, 51, 59 (α9/α5/α7/ α1/α5/α7)						
	1 caz la 36 de ani						

Numai în cazurile cu infecții multiple, nu şi în cele cu infecții unice, am izolat următoarele HPV cu risc crescut: tipul 35 (4 infecții în mediul urban), tipul 39 (4 infecții în mediul urban), tipul 59 (2 infecții în mediul urban), tipul 68 (1 infecție în mediul urban), precum şi tipuri de HPV cu risc scăzut: 61 (3 infecții în mediul urban, 1 infecție în mediul rural), 72 (1 infecție în mediul urban), 54 (6 infecții în mediul urban), 11 (3 infecții în mediul urban), iar HPV cu risc probabil crescut sunt tipurile: 53 (9 infecții în mediul urban), 26 (1 infecție în mediul urban).

Am detectat 59 de infecții la paciente între 20 şi 30 de ani: 29 de infecții unice (dintre care 1 infecție în mediul rural) şi 30 multiple (dintre care 2 în mediul rural).

HPV 16 (grupul α9) cu risc crescut este implicat cel mai frecvent în infecții unice (10 cazuri) şi în infecții multiple: 14 în mediul urban (o pacientă infectată cu 6 virusuri, una cu 5 HPV, 2 paciente cu 4 HPV, 3 paciente cu 3 HPV, 7 paciente cu 2 HPV asociate) şi un caz cu 2 HPV asociate în mediul rural. HPV 52 (grupul α9) cu risc crescut a fost evidențiat în 16 cazuri (4 infecții unice, 8 cazuri cu infecții multiple

cu 2 sau 3 sau 4 HPV şi 4 cazuri cu 2 HPV asociate), predominant tot între 20 şi 30 de ani şi în infecţii multiple, fiind al doilea HPV izolat din infecţii, ca frecvenţă, după tipul 16. Tipul 6 cu risc scăzut este implicat în 6 infecţii unice. Tipurile cu risc crescut 31, 52 şi tipul 66 cu risc probabil crescut sunt implicate fiecare în câte 4 infecţii unice. HPV 51 cu risc crescut este izolat în 10 cazuri: 2 infecţii multiple cu 2 şi 3 HPV asociate şi într-un caz de infecţie multiplă cu 4 HPV asociate. HPV 55 (cu risc scazut) şi HPV 58 (cu risc crescut) sunt implicate fiecare în câte o infecţie unică şi în câte o infecţie multiplă cu 2, respectiv cu 3 HPV asociate. Tipul 55 se identifică şi într-o infecţie cu 4 HPV asociate. HPV 70 şi HPV 83 au fost identificate fiecare în câte o infecţie unică şi în câte o infecţie multiplă cu 2 HPV asociate. HPV CP6108 (cu risc scăzut) a fost implicat într-o infecţie unică şi în 3 infecţii multiple cu 2, 3, respectiv 5 HPV asociate. HPV 26 cu risc probabil crescut a fost izolat numai de la un caz cu infecţie multiplă cu 6 virusuri asociate, datorită posibilităţii de a fi rar implicat în infecţii; nu este exclus să nu fi fost depistat datorită numărului mic de cazuri investigate. Tipul 6 cu risc scăzut a fost implicat in 16 cazuri, fiind al treilea tip de HPV identificat ca frecvenţă.

Nu există diferenţe semnificative ale mediei de *vârstă* raportat la grupul filogenetic al HPV (p=0,26) (tab. IV). Grupele filogenetice din care fac parte HPV implicate în infecţii unice sunt: α1 (1 caz), α3 (5 cazuri), α5 (4 cazuri), α6 (5 cazuri), α7 (5 cazuri), α9 (21 cazuri), α10 (7 cazuri). Grupele filogenetice α11 şi α13 au fost implicate numai în infecţii multiple în mediul urban (HPV din grupul filogenetic α11 în 7 infecţii multiple şi α13 în 6 infecţii multiple).

TABELUL IV

Grupul filogenetic al HPV corelat cu vârsta

p=0,26	N	Media vârstei	Deviaţie standard	Eroare standard	Intervalul de confidenţă pentru medie 95%		Vârsta minimă	Vârsta maximă

Legendă: N = număr de HPV dintr-un grup filogenetic

DISCUŢII

Se consideră că utilizarea metodei hibridizării pentru detectarea HPV ca metodă de screening este mai sensibilă decât utilizarea numai a frotiului pentru detectarea koilocitelor (9), aspect care concordă cu rezultatele noastre.

În studiul prezent, HPV 16 a fost cel

mai frecvent izolat din infecții unice şi multiple în mediul urban şi rural (25 de cazuri = 13,7%), la fel cum rezultă şi din alte cercetări (10, 11). HPV 52 (grupul α9) cu risc crescut are incidență crescută în Asia şi Africa, unde determină 2 – 3 % din totalul cancerului cervical din lume (12); noi am constatat prevalența izolării acestui tip de HPV după tipul 16, situație relatată şi în alte studii (13, 14, 15, 16). Şi alți autori au depistat tipurile de HPV identificate în această lucrare, cum sunt HPV 31, 52, 51, 58, 84 (17) şi respectiv tipurile 26, 6, 55, 70, 83, CP6108 (18).

Numărul mic de cazuri investigate în mediul rural (7 cazuri) se poate datora gradului scăzut de educație; femeile nu se prezintă la medic pentru investigații atât de frecvent ca în mediul urban (19). Totuşi, rata de expunere a femeilor tinere pare a fi mai mare, cu implicarea mai multor tipuri de HPV, ceea ce sugerează deficiențe de educație sexuală.

Nu se constată diferențe semnificative ale mediei de vârstă ale pacientelor raportat la grupul filogenetic al HPV, la fel ca şi în alte cercetări (20). Grupul filogenetic α9 a fost cel mai frecvent implicat în infecția cu HPV, concordant cu alți autori (14).

În studiul din lucrarea prezentă, numai la 9 cazuri a fost efectuat examenul citologic Babeş-Papanicolaou, dintre care la un caz (femeie de 32 de ani din mediul urban) s-a evidențiat ASC-US şi atipii ale celulelor pavimentoase intermediare fără a se identifica vreun tip de HPV. Examenul citologic Babeş-Papanicolaou, deşi se ştie că are sensibilitate limitată, necesită repetare şi determină rate crescute de rezultate fals pozitive; el rămâne metoda standard pentru detectarea LSIL (leziuni intraepiteliale scuamoase de grad scăzut) la femei sub 35 de ani. Testarea prezenței HPV cu risc crescut nu este atât de importantă pentru detectarea LSIL la acest grup de femei. Deşi testarea HPV cu risc crescut este utilă pentru predicția riscului de progresie a bolii, pozitivarea HPV cu risc crescut în LSIL nu indică aplicarea unui tratament chirurgical (conizație) la aceste femei cu vârsta sub 35 de ani (21). Scăderea mortalității legate de cancerul cervical este atribuită implementării programelor de screening, care se recomandă să fie inițiat la aproximativ 3 ani după începerea vieții sexuale, dar nu mai târziu de vârsta de 21 de ani şi să se continue până la vârsta de 65 sau 70 de ani. Utilizarea atât a examenului citologic cât şi a testării HPV la intervale de 3 ani la femei în vârstă de 30 sau peste 30 de ani este comparabilă ca sensibilitate cu efectuarea anuală a examenului citologic pentru detectarea leziunilor precursoare ale cancerului cervical (22).

CONCLUZII

Frecvența infecției genitale cu HPV în populația feminină din arealul abordat este insuficient supravegheată şi cunoscută, fiind investigate eventual paciente cu probleme de sănătate în sfera genitală. Aspectul este mai grav în mediul rural.

Nu se constată diferențe semnificative ale mediei de vârstă funcție de grupul filogenetic al HPV.

HPV tipul 16 (grup α9) apare ca fiind prevalent în infecțiile unice şi multiple diagnosticate la pacientele investigate.

Proporția cazurilor cu infecție unică sau multiplă la femei active sexual din mediul urban este aproximativ egală, sugerând deficiențe generale de educație şi comportament sexual.

Răspândirea HPV – aşa cum este cunoscută acum – este un argument suficient în favoarea vaccinării HPV de masă.

INFLUENCES OF INTERNAL DIFFUSION ON THE LIPIDS BIO-DEGRADATION WITH IMMOBILIZED *BACILLUS SP*. CELLS IN FIXED BED OF BASKET TYPE (Abstract): **Aim:** This paper develops the previous studies on the transfer processes and biochemical reaction kinetics involved in the lipids biodegradation. **Material and methods**: The experiments were carried out in 10 l (8 l working volume) laboratory bioreactor with computer-controlled and recorded parameters. The basket was placed centered around the stirrer and was filed with *Bacillus sp.* cells immobilized in alginate. The optimum impellers combination was found to be of two Rushton turbines, the superior one placed outside the basket and the other inside the basket at its inferior extremity. **Results:** In the investigated case, the influences of the substrate internal diffusion on physical and biochemical processes have been quantified by means of the Biot number, Thiele modulus and reduction factor λ. Compared to the system with free bacterial cells, biochemical processes rate is reduced inside the biocatalyst particle for about 150 - 200 times, this effect being more important than in the case of the bioreactor with mobile bed of immobilized yeast cells. **Conclusions:** The utilisation of immobilized biocatalysts offers many advantages, but allows the unfolding of the internal diffusion of substrate or product, with negative effect on the overall biochemical process evolution. **Key words:** *BACILLUS SP.*, LIPIDS, BIOREACTOR, DIFFUSION.

Lipidele sunt biomolecule organice, de proveniență microbiană, vegetală sau animală, insolubile în apă, însă solubile în solvenți nepolari. Lipidele pot fi complexe (lipide saponificabile), care conțin în structură acizi graşi, incluzând acilgliceroli, fosfogliceride, sfingolipide şi ceruri, sau simple (nesaponificabile), care nu conțin în structură acizi graşi (1).

Dintre lipidele complexe, o clasă aparte o reprezintă triacilglicerolii sau trigliceridele. Această clasă este cea mai cuprinzătoare şi include grăsimile (lipidele în stare solidă la temperatura ambiantă) şi uleiurile. Circa 3% din producția modială de uleiuri vegetale o reprezintă uleiul de măsline, 82% dintre consumatorii săi provenind din Uniunea Europeană. Apele reziduale provenite din industria uleiului de măsline reprezintă un poluant important, datorită

încărcării sale organice ridicate, reprezentate de lipide (0,2-1%), acizi carboxilici (0,5-1,5%), zaharuri (1-8%), polifenoli şi pectine (1-1,5%), compuşi cu azot (0,5-2,4%), taninuri şi polialcooli (2). Majoritatea problemelor asociate cu poluarea generată de aceste ape sunt determinate de fracțiunea fenolică care afectează sever activitatea microorganismelor ecosistemului (3). Pentru epurarea acestor ape reziduale, au fost propuse metode fizice şi chimice (decantare, concentrare, ultrafiltrare, osmoză inversă, flotație, absorbție, oxidare şi fotooxidare), iar, mai recent, şi biologice (4).

Tratarea biologică a apelor cu conținut de ulei s-a realizat în condiții anaerobe sau aerobe, folosind microorganisme din clasa bacteriilor (*Burkholderia cepacia, Phormidium sp., Oscillatoria sp., Chroococcus sp., Enterobacter aerogenes, Mucor racenosus*), drojdiilor (*Candida oleophila, Candida tropicalis, Yarrowia lipolytica*), fungi (*Apergillus niger, Phanerochaete crysosporium, Lentinus edodes, Pleorotus ostreatus, Funalia trogii, Geotrichum candidum, Mucor rouxii, Absidia coerulea, Penicillium restrictum, Penicillium verucosum*) şi *lipaze* libere sau imobilizate. In acest sisteme, trigliceridele sunt biodegradate la acizi graşi cu catenă lungă, care sunt apoi oxidați în poziția β la acetat sau propionat (5). Coexistența unei activități metanogene a microorganismelor implicate în biodegradarea lipidelor manifestă un efect favorabil asupra hidrolizei trigliceridelor.

În acest context, în lucrare au fost analizate performanțele unui sistem de tratare biologică anaerobă a apelor reziduale provenite de la obținerea uleiului de măsline, prin folosirea celulelor de *Bacillus sp.* imobilizate. In acest scop, s-au investigat cinetica biodegradării lipidelor, simultan cu efectul difuziei interne a acestora în granulele de biocatalizatori dispuse într-un bioreactor cu strat fix de tip *"basket"*.

MATERIAL ŞI METODĂ

Echipamentul experimental utilizat a constat dintr-un bioreactor de laborator de 10 l (8 l volum util), de tip Fermac 310/60, Electrolab, prevăzut cu un sistem computerizat de monitorizare, control şi înregistrare a datelor. Stratul tip *„basket"* de biocatalizatori imobilizați a avut o configurație cilindrică, cu diametrul interior de 100 mm, înălțimea de 100 mm şi grosimea de 10 mm. Cilindrul staționar a fost plasat central în jurul axului agitatorului, la distanța de 100 mm de baza bioreactorului (fig. 1).

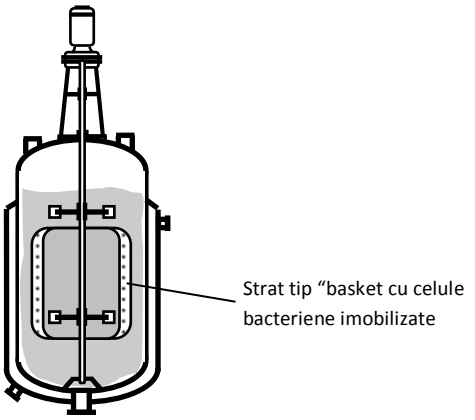

Fig. 1. Bioreactorul experimental tip *"basket"*

Stratul fix a conținut celule de *Bacillus sp.* (*Bacillus subtilis, Bacillus megaterium, Bacillus litheniformis, Bacillus ortoliquefaciens* în proporții egale) imobilizate în alginat de sodiu. Imobilizarea s-a realizat prin tehnica includerii prin reticulare, conform rețetelor existente în literatură (6). În experimente s-au utilizat granule de biocatalizator având diametrul de 3,6 mm. Fracția volumică a biocatalizatorilor a fost de 0,1.

Sistemul de amestecare a constat dintr-un agitator dublu tip turbină Rushton. Turația agitatorului a fost de 150 şi, respectiv,

300 rpm. Durata procesului de biodegradare a fost dictată de viteza de consum a lipidelor totale. Evoluţia procesului s-a realizat prin dozarea lipidelor totale, folosind metoda spectrofotometrică cu trioleină (7).

REZULTATE ŞI DISCUŢII

Pentru stabilirea valorii şi a distribuţiei concentraţiei lipidelor atât la interfaţa mediu-granulă de biocatalizator, cât şi în interiorul granulei de biocatalizator, se consideră bilanţul de materiale al acestora pentru o singură granulă de celule de *Bacillus sp.* imobilizate în alginat. În acest context, variaţia concentraţiei lipidelor cu raza particulei de biocatalizator este redată de expresia:

$$\frac{dC_{LT}}{dt} = D_{LTe} \cdot \left[\frac{1}{r^2} \cdot \frac{d}{dr} \left(r^2 \cdot \frac{dC_{LT}}{dr} \right) \right] - k_{dC} \cdot C_{LT} \qquad (1)$$

în care:

C_{LT} - concentraţia lipidelor totale din mediu, g/l

C_{LTi} - concentraţia lipidelor totale la suprafaţa biocatalizatorilor, g /l

C_{LTP} - concentraţia lipidelor totale în granula de biocatalizator, g/l

D_{LTe} - coeficientul efectiv de difuzie al lipidelor, m^2/s

k_{dC} - viteza specifică de biodegradare a lipidelor, h^{-1}

v_d - viteza de degradare a lipidelor, g/l.h

r - distanţa din centrul granulei de biocatalizator la punctul considerat, m

R_P - raza granulei de biocatalizator, m.

Bi reprezintă criteriul Biot, definit ca măsură a importanţei relative a rezistenţei la difuzie a unui compus prin filmul de lichid de la suprafaţa unei particule, comparativ cu difuzia internă în particulă. In cazul analizat, criteriul Bi se calculează cu expresia (8):

$$Bi = \frac{k_L \cdot R_P}{D_{LTe}} \qquad (2)$$

Variaţia criteriului Bi pentru acest sistem de biodegradare a lipidelor este descrisă grafic în figura 2. Se observă că valoarea acestui criteriu scade pe direcţie radială, datorită dependenţei directe dintre acest criteriul Bi şi coeficientul de transfer de masă al lipidelor prin filmul de lichid de la suprafaţa biocatalizatorilor. Din acelaşi motiv, valorile înregistrate pentru turaţia de 150 rpm sunt semnificativ mai reduse decât cele corespunzătoare turaţiei de 300 rpm.

Diferenţa înregistrată este consecinţa reducerii coeficientului de transfer de masă al lipidelor prin filmul de lichid de la suprafaţa biocatalizatorilor, datorată diminuării turbulenţei în stratul fix şi al creşterii rezistenţei suplimentare corespunzătoare difuziei prin strat.

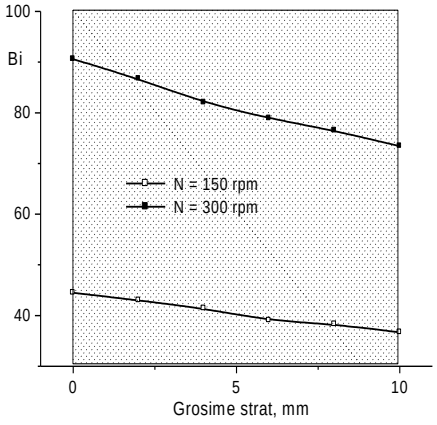

Fig. 2. Variaţia criteriului Biot pe direcţie radială în stratul de biocatalizatori

Un alt parametru ce descrie modul în care difuzia internă influenţează procesul biochimic de consum al lipidelor este modulul

Thiele, φ, definit în acest caz cu relația:

$$\varphi = \frac{R_P}{3} \cdot \sqrt{\frac{k_{dC}}{D_{LTe}}} \qquad (3)$$

Valoarea acestui modul pentru sistemul studiat este 4,10, fiind unică pentru o anumită dimensiune a biocatalizatorilor, indiferent de turația agitatorului. Această valoare, superioară nivelului de referință de 0,1 (9) şi mult mai mare decât în cazul celorlalte sisteme studiate, indică o limitare semnificativă a vitezei reacției biochimice de degradare a lipidelor datorată difuziei interne a acestor compuşi voluminoşi.

Pentru redarea cât mai exactă a efectului generat de difuzia internă asupra biodegradării lipidelor, se utilizează factorul λ, definit ca raportul dintre viteza reacției biochimice în prezența difuziei interne şi viteza aceleaşi reacții în sisteme cu celule libere de *Bacillus sp.* (9). În condiții de staționaritate, se poate considera că viteza reacției biochimice de consum a substratului în interiorul bio-catalizatorilor este egală cu viteza internă de difuzie a substratului. Astfel, în cazul specific al sistemului studiat de biodegradare a lipidelor, relația de calcul a factorului λ devine:

$$\lambda = \frac{4\pi \cdot R_P{}^2 \cdot D_{LTe} \cdot \left.\frac{dC_{LTP}}{dr}\right/_{r=R_P}}{\frac{4}{3}\pi \cdot R_P{}^3 \cdot k_{dC} \cdot C_{LT}} \qquad (4)$$

Deoarece concentrația lipidelor totale în granulele de biocatalizator, C_{LTP}, se calculează cu expresia:

$$C_{LTP} = \frac{Bi \cdot (C_{LT} - C_{LTi})}{\left[e^{-\left(\sqrt{9\cdot\varphi^2\cdot D_{LTe}^2 + R_P^2} + R_P\right)} - e^{\left(\sqrt{9\cdot\varphi\cdot D_{LTe}^2 + R_P^2} - R_P\right)} \right]} \cdot \left[\frac{e^{\left(\sqrt{9\cdot\varphi^2\cdot D_{LTe}^2 + R_P^2} - R_P\right)\cdot\frac{r}{R_P}}}{\sqrt{9\cdot\varphi^2\cdot D_{LTe}^2 + R_P^2} - R_P} - \frac{e^{-\left(\sqrt{9\cdot\varphi^2\cdot D_{LTe}^2 + R_P^2} + R_P\right)\cdot\frac{r}{R_P}}}{\sqrt{9\cdot\varphi^2\cdot D_{LTe}^2 + R_P^2} + R_P} \right] \qquad (5)$$

prin combinarea cu ecuația (4) şi efectuarea simplificărilor se obține:

$$\lambda = \frac{3 \cdot D_{LTe} \cdot Bi \cdot (C_{LT} - C_{LTi})}{R_P{}^2 \cdot k_{dC} \cdot C_{LT}} \cdot \frac{e^{-\left(\sqrt{9\cdot\varphi^2\cdot D_{LTe}^2 + R_P^2} + R_P\right)} + e^{\left(\sqrt{9\cdot\varphi\cdot D_{LTe}^2 + R_P^2} - R_P\right)}}{e^{-\left(\sqrt{9\cdot\varphi^2\cdot D_{LTe}^2 + R_P^2} + R_P\right)} - e^{\left(\sqrt{9\cdot\varphi\cdot D_{LTe}^2 + R_P^2} - R_P\right)}} \qquad (6)$$

Variația factorului λ în interiorul particulei de biocatalizator este indicată în figura 3.

Din analiza alurii dependențelor obținute pentru fiecare turație se poate concluziona că factorul λ variază lent în apropierea suprafeței şi a centrului granulelor. In apropierea suprafeței granulelor de biocatalizator, concentrația mai ridicată a lipidelor, apropiată de cea superficială, conduce la valori ale factorului λ apropiate de 1. Însă, grosimea acestei regiuni superficiale a granulelor se reduce la turația inferioară, datorită diminuării concentrației superficiale a lipidelor şi, implicit, al unei reduceri mai accentuate a concentrației sale pe direcție radială. Variația lentă a factorului λ în regiunea centrală a granulelor se datorează menținerii unui nivel constant redus al concentrației lipidelor în această regiune.

Pe baza acestor rezultate se poate afirma că prin imobilizarea celulelor de *Bacillus sp.* şi dispunerea lor într-un strat fix tip *basket* viteza procesului biochimic de degradare a lipidelor scade considerabil, de 1/λ ori comparativ cu viteza reacției corespunzătoare sistemului conținând celule libere de bacterii. Magnitudinea acestui efect este corelată cu poziția granulelor în interiorul stratului fix şi cu intensitatea amestecării mediului (fig. 4).

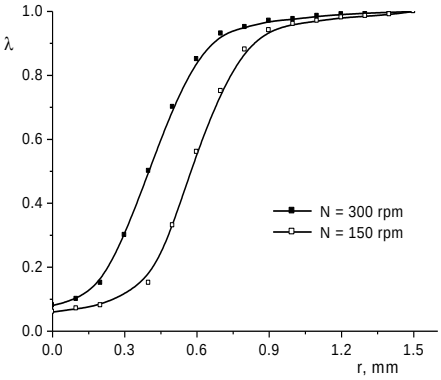

Fig. 3. Variaţia factorului λ cu distanţa de la centrul particulei de biocatalizator

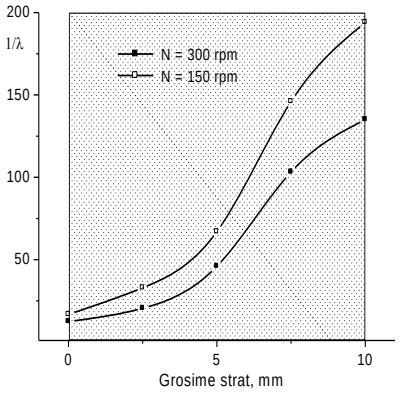

Fig. 4. Variaţia parametrului 1/λ în centrul biocatalizatorilor pe direcţie radială în stratul de biocatalizatori

În acest sens, din motivele discutate anterior, în centrul granulelor, parametrul 1/λ creşte de la suprafaţa interioară a cilindrului la cea exterioară de 10,8 - 11,6 ori, valori superioare fiind înregistrate pentru turaţia de 150 rpm.

CONCLUZII

Utilizarea celulelor imobilizate oferă numeroase avantaje, însă permite apariţia difuziei interne a substratului sau produsului, cu efecte negative asupra evoluţiei procesului biochimic în ansamblul său. In cazul biodegradării lipidelor cu celule de *Bacillus sp.* imobilizate, într-un bioreactor cu strat fix tip „basket", efectul difuziei interne s-a analizat prin intermediul criteriului Biot, al modulului Thiele şi al factorului de reducere λ. Astfel, comparativ cu sistemul conţinând celule libere de *Bacillus sp.,* viteza procesului de biodegradare a lipidelor cu celule imobilizate a scăzut de circa 150 - 200 de ori (valori mai reduse fiind înregistrate pentru turaţii mai ridicate).

EFFECTS OF A *CETRARIA ISLANDICA* EXTRACT IN MONOTHERAPY AND IN ASSOCIATION WITH MAGNESIUM IN AN EXPERIMENTAL-INDUCED HEPATOPATHY MODEL (Abstract): **Aim**: To investigate the effects of a *Cetraria islandica* extract in an animal model of hepatopathy. **Material and methods**: The experiments were carried out on Wistar rats, treated intraperitoneally (excepting carbon tetrachloride which was administered orally by esogastric tube), at single daily dose, for 28 days and divided in eight groups of 6 rats each: Group 1: Saline solution (0.5ml/100g bw/day); Group 2: $MgSO_4$ (5mg/kbw/day); Group 3: *C. islandica* (Ci) extract (21.56mg/kbw/day); Group 4: Ci+$MgSO_4$; Group 5: carbon tetrachloride (CT) (0.1ml/100g bw/day); Group 6: CT+$MgSO_4$; Group 7: CT+Ci; Group 8: CT+Ci+$MgSO_4$. At the end of the experiment blood samples were taken to assess the effects on the blood parameters,TGO, TGP, GGT, LDH, serum total billirubin, neutrophil phagocytic function (Nitroblue tetrazolium test) and serum complement activity. This parameters were determined with VITROS 750 XRC device, using Johnson&Johnson kits. The results were statistically processed with the help of „t-Student" test. $p<0.05$ was considered statistically significant. **Results**: In this carbon tetrachloride-induced hepatopathy animal model, *C. islandica* extract demonstrated hepatoprotective and immuno-stimulating effects (proved by normalization of glutamic-pyruvic transminase, glutamic-oxalocetic transminase, serum total billirubin, stimulation of neutrophils percentage and phagocytic functions, decreasing the carbon tetrachloride-induced basophilia and monocytosis, especially in association with magnesium). **Conclusions**: Further studies are required to confirm the benefits of this association in hepatoprotective and immunomodulating therapies.
Key words: *CETRARIA ISLANDICA*, MAGNESIUM, CARBON TETRACHLORIDE.

S-a demonstrat că un număr tot mai mare de principii active de origine vegetală prezintă efecte imunomodulatoare sau/şi antiinflamatoare, motiv pentru care în medicina tradiţională a unor ţări, constituie adjuvanţi de bază în tratamentul unor boli (medicina tradiţională indiană, chineză, japoneză, etc.) (1).

Dintre imunomodulatoarele vegetale, „adaptogenii" măresc capacitatea organismului de a se adapta la stres şi la alte situaţii cu risc pentru sănătate. Mecanismele prin care aceştia acţionează sunt încă neclare, dar

se pare că este vorba de o interacțiune a efectelor diverselor principii active (2).

Cetraria islandica face parte din familia *Parmeliaceae* cu denumirea populară: lichen de piatră, mușchi creț de munte, mușchi de piatră, lichenul renilor, lichen de Islanda. Crește în majoritatea țărilor nordice, pe stâncile și platourile din zona alpină. Date din literatură evidențiază acțiunea antitumorală și imunomodulatoare a polizaharidelor din structura acestei specii (3), iar asocierea magneziului ($MgSO_4$) potențează efectele extractului de *C. Islandica* (4, 5).

Scopul studiului a constat în cercetarea experimentală a efectelor unui extract din *C. islandica* în monoterapie sau în asociere cu $MgSO_4$ pe un model de hepatopatie indusă la animale de laborator.

MATERIAL ŞI METODĂ

Au fost utilizate 8 loturi de câte 6 șobolani Wistar, cu greutate cuprinsă între 180-200g, cu repartiție uniformă pe sexe, proveniți de la Institutul de Sănătate Publică din Iași, tratați conform schemei: L1 = SF = Ser fiziologic (0,5ml/100g c/zi); L2 = $MgSO_4$ = $MgSO_4$ (5mg/kg c/zi); L3 = Ci = Extract din C. islandica (21,56mg/kg c/zi, reprezentând 1/80 din DL_{50}); L4 = Ci + $MgSO_4$= Ci (21,56mg/kg c/zi) + $MgSO_4$ (5mg/kg c/zi); L5 = TC = Tetraclorură de carbon (0,1 ml/100g c/zi); L6 = TC+$MgSO_4$ = TC (0,1ml/100g c/zi) + $MgSO_4$ (5mg/kgc/zi); L7 = TC+Ci = TC (0,1 ml/100gc/zi) + Ci (21,56mg/kgc/zi); L8 = TC+Ci+MgSO4 = TC (0,1ml/100g c/zi) + Ci (21,56mg/kgc/zi) + MgSO4 (5mg/kgc/zi). Substanțele au fost administrate în doză unică zilnică, la ora 8 dimineața, timp de 28 zile, pe cale intraperitoneală, cu excepția TC, care a fost administrată pe cale orală, pe sondă esogastrică (6,7).

După 28 zile de tratament s-a recoltat sânge din plexul retroorbitar și au fost determinați următorii parametri: formula leucocitară, capacitatea de fagocitoză a PMN din sângele periferic (testul NBT), activitatea complementului seric, valorile transaminazei glutamice oxaloacetice (TGO), transaminazei glutamice piruvice (TGP), gama-glutamiltransferazei (GGT), lactat dehidrogenazei (LDH), bilirubinei serice totale, colesterolului total, LDL-colesterolului și HDL-colesterolului. Aceşti parametri au fost determinați cu un analizor pentru teste biochimice VITROS 750 XRC, folosind reactivi Johnson&Johnson. Rezultatele au fost prelucrate statistic folosind testul „t-Student". Valoarea $p<0,05$ a fost considerată semnificativă statistic.

Cercetările au fost realizate în conformitate cu recomandările Comisiei de Etică a Universității de Medicină și Farmacie „Gr. T. Popa" din Iași, în strictă concordanță cu reglementările etice internaționale, privind lucrul pe animale de laborator (8).

REZULTATE ŞI DISCUȚII

Tetraclorura de carbon (TC) a determinat o scădere semnificativă statistic a procentelor de PMN din sângele periferic, față de lotul martor tratat cu SF. Mg administrat sub forma $MgSO_4$ a determinat o creştere semnificativă statistic a procentelor de PMN din sângele periferic comparativ cu loturile martor tratate cu SF, similar cu cea determinată de extractul din *C. Islandica*. Asocierea Mg la extractul de *C. islandica* a produs o creştere a efectului stimulator asupra acestui parametru indus de *C. islandica*, dar fără semnificație statistică ($p>0,05$).

TC a determinat o scădere semnificativă statistic a procentelor de limfocite din sângele periferic față de lotul martor tratat cu SF. Mg şi extractul din *C. islandica* nu au determinat modificări semnificative statistic ($p>0,05$) ale procentelor de limfocite din sângele periferic comparativ cu lotul martor tratat cu SF. Asocierea Mg la extractul de *C.*

islandica a diminuat scăderea procentului de limfocite din sângele periferic determinată de TC.

La animalele din toate loturile testate nu au fost constatate modificări semnificative statistic ale procentelor de eozinofile din sângele periferic față de lotul martor tratat cu SF ($p>0,05$).

Administrarea TC a determinat o bazofilie şi o monocitoză semnificative statistic față de lotul martor ($p<0,05$). Atât extractul vegetal din *C. islandica*, la doza utilizată în acest experiment, cât şi Mg administrat sub forma $MgSO_4$, nu au antagonizat efectul produs de TC asupra acestor parametri. În schimb, asocierea Ci cu Mg a determinat diminuarea semnificativă statistic a efectului TC de creştere a procentelor de bazofile şi de monocite din sângele periferic comparativ cu lotul martor ($p<0,05$).

Administrarea TC a determinat o scădere semnificativă statistic ($p<0,05$) a capacității de fagocitoză a PMN din sângele periferic față de SF (fig. 1).

Extractul vegetal din *C. islandica*, la doza utilizată în acest experiment, a determinat o creştere semnificativă statistic a valorilor testului NBT comparativ cu SF, atât în cazul administrării în monoterapie, cât şi în cazul asocierii cu Mg. Efectul s-a menținut şi la animalele cu hepatită toxică indusă experimental, efectul fiind semnificativ statistic mai puternic în cazul asocierii Ci cu Mg ($p<0,01$).

La animalele din toate loturile testate nu au fost constatate modificări ale activității complementului seric (UCH_{50}) comparativ cu SF (fig. 2).

S-a constatat că TC a determinat o alterare hepatică profundă, evidențiată prin creşterea semnificativă statistic ($p<0,01$) a valorilor enzimelor TGP şi GGT, precum şi a bilirubinei serice totale față de lotul martor (fig. 3, 4, 5).

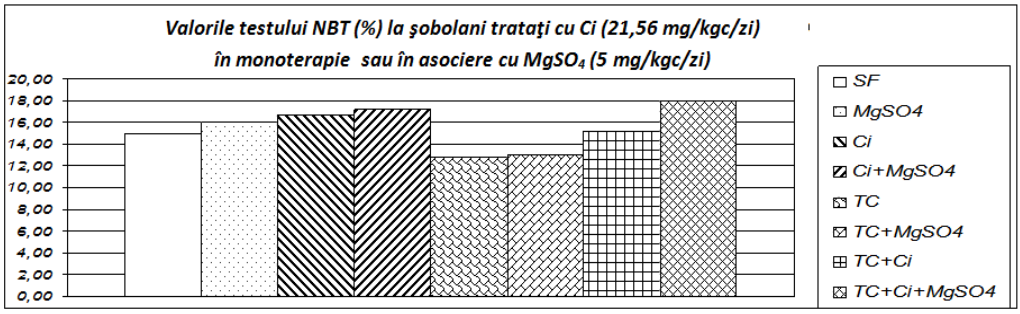

Fig. 1. Valorile testului NBT la 28 zile de la debutul studiului

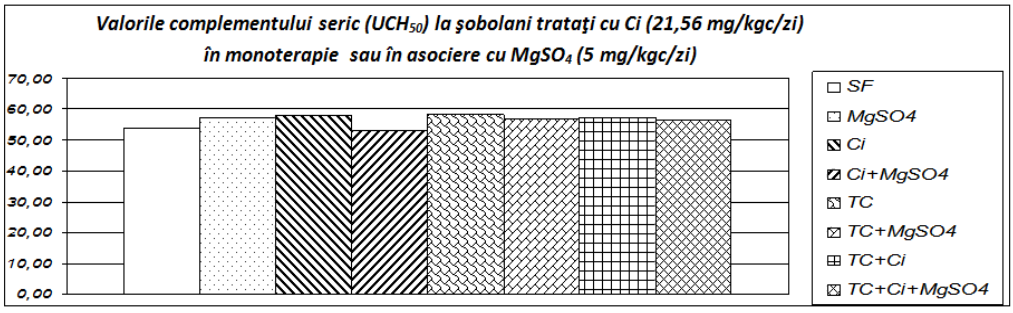

Fig. 2. Activitatea complementului seric la 28 zile de la debutul studiului

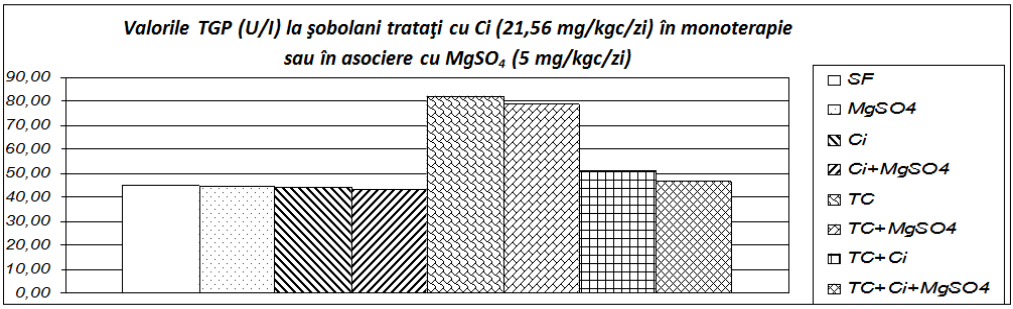

Fig. 3. Activitatea TGP la 28 zile de la debutul studiului

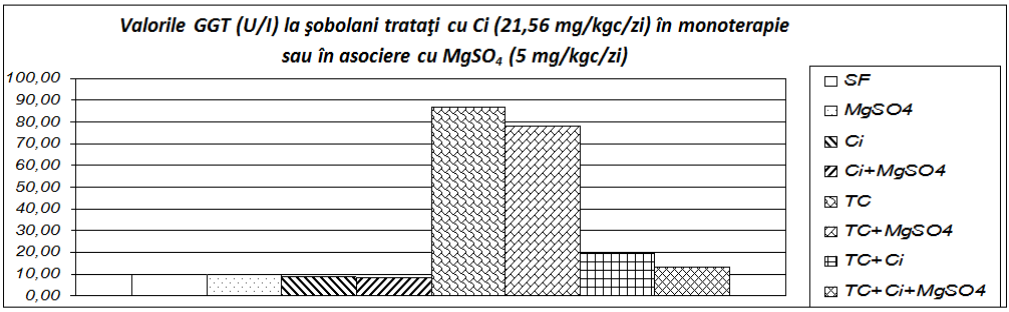

Fig. 4. Activitatea GGT la 28 zile de la debutul studiului

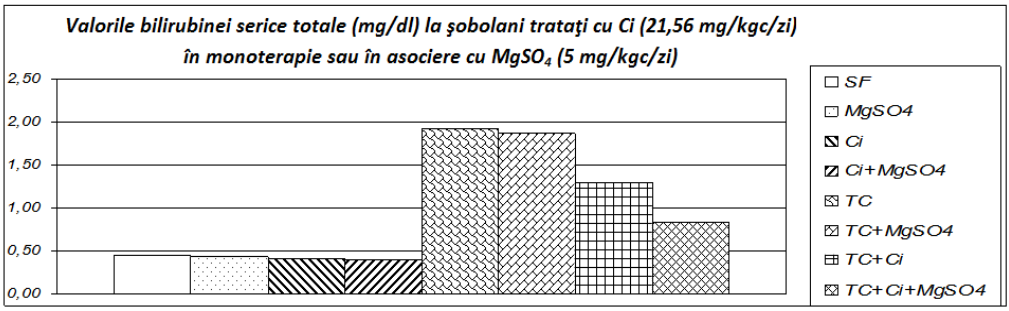

Fig. 5. Valorile bilirubinei serice totale la 28 zile de la debutul studiului

Extractul vegetal din *C. islandica* a determinat o scădere semnificativă statistic a valorilor enzimelor TGP şi GGT, precum şi a valorilor bilirubinei serice totale, atât în cazul administrării în monoterapie, cât şi în cazul asocierii cu Mg, nivelurile revenind la limitele normale. Efectul este semnificativ statistic mai puternic în cazul asocierii Ci cu Mg la animalele cu hepatită toxică indusă experimental, dar Mg în monoterapie nu influenţează aceşti parametri ($p>0,05$).

La animalele din toate loturile testate nu s-au constatat modificări semnificative statistic ($p>0,05$) ale valorilor TGO, LDH, colesterolului total, LDL-colesterolului şi HDL-colesterolului comparativ cu lotul martor tratat cu SF.

Extractul vegetal testat a determinat efecte imunostimulatoare şi hepatoprotectoare, care au fost potenţate prin asocierea cu Mg,

ceea ce sugerează ipoteza utilizării ulterioare a acestei asocieri, în urma unor multiple testări, ca alternativă de medicament sau adjuvant terapeutic hepatoprotector şi imunostimulator (2).

CONCLUZII

Studiile experimentale privind proprietăţile farmacologice ale extractului obţinut din produsul vegetal *C. islandica* (codificat Ci), în doză reprezentând 1/80 din DL_{50} (21,56mg/kgc/zi), administrat în monoterapie sau în asociere cu Mg, sub formă de $MgSO_4$, la animale cu hepatopatie indusă experimental cu tetraclorură de carbon, au condus la următoarele concluzii:

- Ci a determinat o creştere semnificativă statistic a procentului PMN şi a funcţiei fagocitare a acestora, efectul menţinându-se şi la animalele cu hepatopatie indusă experimental;
- în monoterapie, extractul testat nu a influenţat semnificativ statistic scăderea procentului limfocitelor la animalele cu hepatită indusă experimental, dar, în asociere cu Mg, s-a produs o ameliorare semnificativă a acestui parametru în condiţiile experimentale menţionate;
- în asociere cu Mg, extractul vegetal a determinat diminuarea bazofiliei şi a monocitozei la şobolanii Wistar, cu hepatită indusă experimental;
- extractul vegetal, atât în monoterapie cât şi în asociere cu Mg, nu a influenţat semnificativ statistic componenta umorală testată (activitatea complementului seric);
- extractul vegetal, atât în monoterapie cât şi în asociere cu Mg, a ameliorat afectarea hepatică indusă cu TC.

Efectele hepatoprotectoare şi imunostimulatoare au fost semnificative la animalele cu hepatopatie indusă experimental, situaţie ce ar putea fi speculată terapeutic în eventualitatea introducerii ulterioare a acestei asocieri în rândul produselor adjuvante hepatoprotectoare şi al terapiei imunomodulatorilor de generaţia a II-a (imunomodulatori de origine vegetală).

RARE CLINICAL SITUATONS OF THE DIVERTICULI OF THE COLON **(**Abstract): It is well known that the diverticuli of the colon gets inflamed in10-15% of cases, thus becoming clinical symptomatic as a diverticulitis, while in other 15% they will bleed, with the clinical aspect of an inferior digestive bleeding. Our study presents some clinical observations with diverticuli of the colon, that raised diagnostic and therapeutic problems. **Material and method:** Between 2001-2010, 17 patients were admitted in the 3rd Surgery Clinic, University Hospital "St.Spiridon", Iasi, with asymptomatic diverticuli of the colon, that were put in evidence imagistically , intraoperative or on specimens after removal of the colon for other conditions;meanwhile, there were 15 patients admitted with complications of the diverticuli:5 patients had perforated diverticulitis (4-pericolic abscesses and one with peritonitis in the lower abdomen), 4 had rectal bleeding and the other 6 raised particular problems of diagnostic and treatment, being included in the present study. **Results:** Five out of six underwent operation. One patient refused the surgical treatment. Postoperative evolution was favorable in 4 out of the 5 operated patients. **Conclusions:** The complications of colonic diverticuli present on admission under clinical aspects that usually mimic a colonic cancer. In these situations the imagistic examinations do not offer enough details to elucidate the diagnosis. Our six particular observations strengthen the dictum of avoiding the "mirage" of the first lesion. The extent of the surgical procedure in the case of patients with colonic diverticuli admitted under the clinical aspect of a complication is sometimes disproportionate and encumbered of increased mortality and complication rate. **Key words:** DIVERTICULI, DIVERTICULITIS, PERICOLIC ABSCESS

Este cunoscut faptul că diverticulii colonului, în procent de 10-15%, se pot inflama și se manifestă clinic prin tabloul diverticulitei (1; 2), pentru ca, în alte 15% din cazuri, să se complice cu hemoragie, exteriorizată sub forma hemoragiei digestive inferioare. Pacienții cu diverticulite pot prezenta la data diagnosticului una sau mai multe complicații: abcese peridiverticulare sau extinse în vecinătate, obstrucția colonului, perforația, fistulizarea sau o sângerare importantă. Este adevărat că cei mai mulți pacienți nu prezintă nici o simptomatologie până la internarea în spital, când se prezintă cu o complicație a diverticulozei. Tot atât de adevărat este faptul că un pacient cunoscut cu diverticuloză colică poate avea, la data internării în spital, o altă patologie colonică, după cum sunt posibile complicații rare ale diverticulitei. Lucrarea de față prezintă o serie de observații clinice care au pus probleme de diagnostic și atitudine terapeutică.

MATERIAL ȘI METODĂ

În perioada 2001-2010, în Clinica a III-a Chirurgie Iași, au fost internați 15 pacienți cu diverticulită colonică. Dintre aceștia, cinci pacienti au prezentat diverticulite perforate (cu abcese pericolice-4, și unul cu peritonită submezocolică), patru au prezentat tabloul clinic al unor rectoragii, iar celelalte șase observatii au ridicat probleme particulare privind diagnosticul și tratamentul, făcând obiectul acestei lucrări. În aceeași perioadă au fost internați în clinică, pentru alte afecțiuni (cancere colonice, polipoze colonice, sindroame subocluzive prin aderențe postoperatorii), alți 17 pacienți cu diverticuli colonici asimptomatici și care au fost puși în evidență prin clisma baritată, precum și intraoperator sau pe piesele de rezecție.

Bolnava I.E., 48 ani, se internează în clinică pentru constipație, durere hipogastrică, rectoragii minore, febră 38-39° C., cu caracter intermitent. Tușeul rectal constată ampula rectală goală, cu urme de sânge proaspăt pe mănușa degetului explorator. Rectosigmoidoscopia evidențiază mucoasa rectală edematiată și ușor eritematoasă până la 18 cm de marginea anală, pentru ca, de la acest nivel, să devină intens edematiata, hiperemică, cu îngustarea bruscă a lumenului, impiedicând progresia colonoscopului. Datele de laborator: hematurie microscopică, leucocitoză (16.000/mm³) și anemie moderată (Hb:7,8gr%, Ht:36%). Ecografic se constată o formațiune pelvină, ecogenă, situată retrouterin și deasupra domului vezical, în vecinătatea căreia se găsește o colecție de 4/5 cm. În acest context se formulează diagnosticul de cancer rectosigmoidian cu abces perineoplazic și răsunet septic; se intervine chirurgical, descoperindu-se un bloc pelvin sângerând ușor la manevrele de disecție; pe parcursul acesteia se deschide o colecție purulentă, fetidă, cu caracter de infecție cu E. Coli, care se evacuează și se drenează. Operatorul consideră că diagnosticul este de cancer rectosigmoidian și practică un anus iliac stâng în continuitate. Postoperator se administrează antibiotice conform antibiogramei din secreția evacuată și antiinflamatorii. I se recomandă pacientei control după trei săptămâni de la externare; revine în clinică după șase săptămâni, când se practica o rectosigmoidoscopie cu intenția efectuării unei biopsii, care să certifice diagnosticul de cancer. Surpriza este la examenul rectosigmoidoscopic, care constată lumen rectocolic permeabil până la stoma, cu mucoasa rectală cu discrete caractere inflamatorii. Se efectuează o clismă baritată care pune în evidență multipli diverticuli sigmoidieni; suspiciunea de cancer sigmoidian este infirmată. Se practică colectomie stângă joasă cu colorecto anastomoză, cu evoluție favorabilă. *Particularitatea* cazului: bolnava tânără, internată cu diagnosticul de cancer sigmoidian stenozant, cu abces perineoplazic, sângerând, diagnosticul fiind diverticulită.

Bolnava I.A., 70 ani, purtătoare de diverticuli pe colonul descendent și sigmoid (evidențiați prin clismă baritată), se internează pentru dureri în fosa iliacă stângă, constipație și febră 38°C. Examenul obiectiv constată o formațiune în fosa iliacă stângă, fixă și dureroasă. Radiografia abdominală simplă arată o moderată distensie a cadrului colic, iar din probele de laborator de reținut a fost leucocitoza (15.000/mm³). Clisma baritată pune în evidență o imagine de stop parțial pe bucla sigmoidiană, sugerând diagnosticul de cancer sigmoidian. Se formulează diagnosticul de cancer al colonului stâng cu abces perineoplazic și se intervine chirurgical. Se constată o formațiune cu caractere macroscopice de cancer, situată pe bucla sigmoi-

diană, fixată parietal prin aderențe inflamatorii, care prin liză duc la evacuarea unei colecții purulente. Se drenează abcesul și se practică operația Hartmann. Surpriza apare atunci când piesa de rezecție este secționată: pe peretele sigmoidian se găsesc numeroși diverticuli, dar în mijlocul masei pseudotumorale se află un os de pasăre, ascuțit (clavicula), înfipt în peretele colonului prin baza unui diverticul, pe care-l perforează. Evoluția postoperatorie a fost simplă. *Particularitatea* cazului: corp străin care perforează peretele sigmoidian la nivelul unui diverticul, mimând astfel tabloul clinic al unui cancer sigmoidian perforat, cu abces perineoplazic.

Bolnavul A.P. 66 ani, aflat sub tratament cronic cu anticoagulante dicumarinice pentru o afecțiune valvulară, se internează în clinică pentru rectoragii abundente, paloare, tahicardie (110 bătăi/min), tendință la lipotimie. Din probele de laborator, de reținut: anemie: Hb. 7,8gr.%, un indice de protrombină (I.P.) de 70% . Dupa șase zile de expandare volemică, hemostatice și administrare de plasmă, sângerarea se oprește și face posibilă efectuarea rectosigmoidoscopiei, care decelează un polip pediculat ulcerat lung de 5 cm, care se excizează pe cale endoscopică. Rectul și sigmoidul nu prezintă, aparent, alte leziuni. Pacientul se externează, dar după două luni se reinternează cu rectoragii și sensibilitate dureroasă în fosa iliacă stângă. Se instituie tratament hemostatic cu oprirea hemoragiei și efectuarea ulterioară a clismei baritate care deceleaza multipli diverticuli pe colonul sigmoid, descendent și a trei diverticuli pe colonul transvers. Se propune pacientului intervenția chirurgicală (fiind la a doua sângerare), dar pacientul refuză și se externează. Evolutia ulterioară a fost bună, pacientul fiind pierdut din evidență după un an de la ultima internare. *Particularitatea* cazului: un polip voluminos, pediculat și ulcerat, s-a comportat pentru endoscopist ca sursă sigură a sângerării, neexplorarea restului cadrului colic fiind pusă pe seama "mirajului" primei leziuni, sângerarea fiind dată de diverticulii colonului sigmoid.

Bolnava C.M., 83 ani, diagnosticată cu sindrom de colon iritabil și diverticuloză a colonului stâng, se internează pentru durere în fosa iliacă stângă, anorexie, diaree asociată cu rectoragii minore, stare subfebrilă. În antecedente se remarcă episoade dureroase de intensitate moderată în fosa iliacă stângă. Examenul fizic decelează moderată distensie abdominală și durere moderată la palparea cadranului inferior stâng al abdomenului. Întrucât există în antecedente diagnosticul de diverticuloză, se etichetează suferința în cadrul diverticulitei colonului stâng și se instituie antibioterapia, administrarea de antiinflamatorii, repaos digestiv, expandare volemică și alimentație parenterală timp de șapte zile. Tratamentul instituit duce la remiterea simptomelor de la internare, iar scaunul se normalizează; se reia alimentația per os și pacienta se externează. După cinci săptămâni reapar rectoragiile, cu tabloul clinic al unei anemii secundare, motiv pentru care pacienta se reinternează. Explorarea endoscopică, efectuată atent acum, decelează doi polipi de 17 și respectiv 10 mm, ulcerați și sângerânzi, localizați la 8 și respectiv 9 cm de marginea anală. Se practică polipectomia pe cale transanală; evoluția favorabila, la doi ani de supraveghere. *Particularitatea* cazului: bolnava vârstnică, cunoscută ca purtătoare de diverticuli colonici, sângerează iterativ din doi polipi adenomatoși și nu din diverticuli.

Bolnava S.E. 49 ani, fara un istoric personal de boală, se internează în urgență pentru dureri abdominale difuze, brusc instalate, după o perioada de trei zile de con-

stipație, febră, frisoane, contractură abdominală generalizată, prăbușirea T.A., tahicardie, tahipnee, sugerând diagnosticul de peritonită generalizată. Ecografia decelează lichid abundent în întreaga cavitate peritoneală. Laparotomia efectuată în urgență găsește lichid fecaloid abundent submezocolic și în cantitate mai mică supramezocolic; în hipogastru se găsește un bloc tumoral de aproximativ 20 cm, aparținând colonului sigmoid, care pare că invadează anexa stângă și fața posterioară a uterului. Detașarea acestei formațiuni de uter și anexa stangă fiind imposibil de realizat, se practică ablația monobloc a jumătății inferioare a sigmoidului înglobând tumora (piesa de rezecție: 22 cm), a uterului și a anexelor, cu închiderea bontului rectal, inflamat și îngroșat și colostomie terminală; lavaj și drenaj larg al peritoneului, cu evoluție postoperatorie favorabilă în cadrul terapiei intensive. Surpriza diagnostică e dată de examenul histopatologic la parafină, care constată un important proces inflamator, difuz, cu îngroșarea accentuată a peretelui colonic și prezența a numeroși diverticuli și a unui polip sesil cu displazie epitelială severă, situat la 8 cm de capătul distal al rezecției. Pacienta revine la 2 luni de la operație, când se efectuează colonoscopie pentru restul colonului, prin anusul iliac, și rectoscopie, care exclude existența altor polipi. Se efectuează repunerea în circuit, prin anastomoză mecanică. Evoluție postoperatorie favorabilă. *Particularitatea* cazului: bolnava tânără cu diverticulită perforată ca prim simptom, cu peritonită generalizată, sepsis sever, mimează ca diagnostic un cancer colonic perforat. Interesantă este asocierea polipului cu displazie epitelială severă, care a fost îndepartat odată cu tumora.

Bolnava I.B. 68 ani, se internează în clinică cu febră (38,7°C), frisoane și durere în flancul stâng. Laborator: leucocitoza: 16.000/mm³, uree:1,20gr/l, creatinina: 1,80 g/l. Ecografia decelează o colecție cu caracter purulent, localizată în flancul stâng, iar radiografia abdominală simplă arată o distensie moderată a cadrului colic. Tomografia computerizată (T.C.) cu substanță de contrast nu a putut fi efectuată datorită valorilor ridicate ale ureei și creatininei. Istoricul pacientei e nesemnificativ. Întrucât evoluția bolii s-a agravat, cu toata terapia intensiva aplicată, s-a intervenit chirurgical la 48 ore de la internare, găsindu-se o masă cu caracter tumoral situată pe colonul descendent și o colecție purulentă de vecinătate, fuzată retroperitoneal, în spațiul parietocolic stâng. Se evacuează colecția și, întrucât formațiunea părea stenozantă, destinzând colonul suprajacent, se practică o colectomie stângă înaltă cu colo-colo anastomoza. Piesa de exereză conține o formațiune de 6/4 cm, cu aspect tumoral, iar colonul din vecinătate numeroși diverticuli și important proces inflamator, extins și la ciucurii epiploici, mimând un adenocarcinom al colonului. Evoluția postoperatorie imediată a fost nefavorabilă, prin instalarea dezunirii anastomozei, peritonită și șoc septic. Examenul histopatologic infirmă diagnosticul de cancer și constată un proces inflamator cu importantă îngroșare a peretelui colic, cu tendință la stenoză, precum și prezența a numeroși diverticuli. *Particularitatea* cazului: diverticulita perforată cu abces de vecinătate fuzat retroperitoneal, la o pacientă cu fenomene subocluzive, a sugerat un cancer al colonului stâng, cu abces de vecinătate, diagnostic sugerat și de aspectul macroscopic al piesei de exereza. Examenul histopatologic a infirmat însă diagnosticul de adenocarcinom; evoluția nefavorabilă poate fi prevenită printr-o operație de tip Hartmann.

DISCUȚII

Mulți pacienți cu diverticuloză rămân asimptomatici pe tot parcursul vieții lor, și numai 10-25% vor deveni simptomatici în cadrul diverticulitei (1). Statisticile estimează că un număr de 15-20% dintre pacienți vor face hemoragie diverticulară și, din acest grup, 80% beneficiază numai de măsuri terapeutice vizând expandare volemică, administrare de hemostatice și sânge, fără a necesita tratament chirurgical. Aproape jumătate din pacienți au episoade anterioare de sângerare (2), iar examenul fizic nu poate să precizeze sediul sângerării. Colonoscopia, pentru o serie de autori, ar avea o acuratețe diagnostică de până la 86% din cazuri în privința depistării sursei sângerării (3). Ca și în alte situații întâlnite în explorarea imagistică, colonoscopia trebuie să evite mirajul primei leziuni; depistarea unui polip colonic ulcerat și ablația acestuia nu exclude explorarea ulterioara a întreg cadrului colic, pentru a nu scăpa sursa reală a sângerării, așa cum a fost la una din observațiile noastre. Pe de altă parte, diagnosticul de diverticuloză a colonului, stabilit imagistic cu ani în urmă, nu exclude existența altor cauze de sângerare exteriorizată prin rectoragie sau hematochezis; în acest sens, prezenta unor polipi rectali sau colonici poate fi cauza sângerării, situație întâlnită la o alta observație a noastră. Ca urmare, arteriografia mezenterica selectivă în urgență este o explorare imagistică utilă, permițând identificarea sursei sângerării în pana la 60% din cazuri (4), iar în același timp poate fi și o soluție terapeuticță pemițând oprirea sângerării (instilare de vasopresină sau embolizări). (5). Este adevărat ca la un pacient vârstnic, prezența unei suferințe abdominale acute localizată în fosa iliacă stângă sau flancul stâng sugerează diagnosticul spre o diverticulită, eventual cu abces de vecinătate. Totuși, trebuiesc luate în discuție și alte afecțiuni chirurgicale acute, cum ar fi cancerul colonului stâng perforat, cu abces perineoplazic, un abces perinefretic stâng sau uropionefroză. Din acest motiv trebuie apelat la T.C., care poate defini riscul individual și atitudinea terapeutică. (6). Cea mai mare acuratețe diagnostică o are T.C., cu condiția ca explorarea să se facă cu substanță de contrast, dacă nu există contraindicații, situație întâlnită și la una din observațiile noastre. Explorarea imagistică (colonoscopia, clisma baritată) în diverticulite, are riscul de a rupe abcese peridiverticulare, cu extravazarea bariului ca și a conținutului colonic în cavitatea peritoneală (7). Diverticulitele situate pe partea stângă, la pacienții tineri, s-au dovedit a fi, în cazuistica noastră, mai "virulente" și cu un risc crescut de perforație și recurență, așa cum se citează și în alte studii (8). Starea septică se instalează repede, iar răsunetul sistemic nu permite efectuarea C.T. cu substanță de contrast. Desigur, exista și situații foarte rare când un corp străin se inclavează într-un diverticul al colonului, declanșând un proces inflamator la nivelul peretelui și în final perforează diverticulul, cu apariția unui abces pericolic, așa cum s-a întamplat la una din observațiile noastre. Diverticulitele pot realiza progresiv o obstrucție a colonului, rareori completă. Se pot asocia cu abcese diverticulare, retroperitoneale, mezenterice sau pelvine. Uneori obstrucția colonului se asociază cu un abces pericolic, mimând un cancer, iar explorarea intraoperatorie nu poate face diferența între cele două afecțiuni. În literatura de specialitate nu există studii randomizate care să compare cele două procedee operatorii, operația Hartmann *versus* rezecția colonică cu anastomoză primară, la bolnavii cu diverticulită perforată. Există multiple publicații care compară rezultatele după cele doua procedee și care caută să arate un beneficiu privind scăderea morbidității și a mortalității după

anastomaza primară (9,10,11,12,13), dar pe un număr redus de pacienți, pe loturi neomogene ca leziuni anatomopatologice. Un studiu recent, pe pacienti atent selecționați, cu diverticulite perforate, demonstrează clar că operația Hartmann rămâne opțiunea sigură, în special la pacienții în vârstă, cu multiple comorbidități (14), atitudine la care ne raliem și noi.

CONCLUZII

Complicațiile diverticulozei colonice îmbracă uneori aspecte clinice mimând cel mai frecvent cancerul și la aceste cazuri explorarea imagistică nu oferă date suficiente pentru elucidarea diagnosticului.

Aceste observații particulare întăresc și mai mult dictonul de a evita, pe cât posibil, "mirajul" primei leziuni.

Amploarea intervenției chirurgicale în cazul diverticulilor colonici care se prezintă la internare sub forma complicațiilor este, uneori, disproporționată și grevată de complicații și mortalitate crescute.

MEDICAL-SOCIAL ISSUES OF THE MIGRATION OF THE MEDICAL STAFF (Abstract): The migration of the medical staff represents an increasingly worring reason for romanian health policy-makers. According to the Ministry of Health, in 2009 year, the human resources indicators pointed out 26.5 physicians/ 10,000 inhabitants (whereas the European Union average was 32.8) and 60,4 nurses and midwives (whereas the European Union average was 108.5). Between 2007-2010, over 9000 physicians requested professional certificates in order to practice abroad and the majority have left the country. This phenomenon is related to the Romania's entrance in European Union and it is supposed to continue in the coming years. The direct consequences of the migration of the medical staff consist of significant differences between the country's regions in the health workforce distribution, the most affected by the critical shortage of health service providers being the North-Eastern region, especially in rural area. In order to limit the migration phenomenon, the Ministry of Health elaborated some strategies and workforce policies on medium and long-term, but the results will be difficult to assess. **Key words**: MIGRATION, MEDICAL STAFF, CRITICAL SHORTAGE

După Al Doilea Război Mondial în țările Europei Centrale şi de Est, cu excepția Yugoslaviei, s-a impus modelul sovietic de tip Semaşko de organizare a îngrijirilor de sănătate.

Vreme de câteva decenii în România, ca şi în țările învecinate, s-a reuşit acoperirea întregii populații şi accesul gratuit la îngrijirile de sănătate. Sistemul sanitar era controlat de guvern printr-o planificare centralizată, personalul era remunerat pe bază de salariu, nu exista practică privată, şi totuşi starea de sănătate a populației din Europa Centrală şi de Est era comparabilă, până la mijlocul deceniului şase din secolul trecut, cu cea din Vestul Europei (1). A urmat o deteriorare progresivă a stării de sănătate a populației, consecință a înrăutățirii condițiilor de viață datorită cheltuielilor militare, subfinanțării serviciilor de sănătate şi a unei organizări ineficiente.

Din 1990 şi până în prezent, sistemul de sănătate din țara noastră a parcurs două decenii marcate de numeroase schimbări, prin trecerea de la un sistem centralizat, finanțat integral de la bugetul de stat, la unul bazat pe asigurările sociale de sănătate. În domeniul resurselor umane, România se

confruntă de mulți ani cu un deficit, având una dintre cele mai mici rate europene de acoperire cu personal medico-sanitar (2).

După aderarea României la Uniunea Europeană, începând cu 1 ianuarie 2007, emigrația (sau intenția de emigrare) a personalului medical a devenit o preocupare majoră pentru asociațiile profesionale din domeniu.

SITUAȚIA ACTUALĂ

O analiză a resurselor umane în România, evidențiază în ultimele patru decenii, creşterea treptată a numărului de medici, farmacişti şi asistente medicale (3) (tab. I).

TABELUL I

Evoluția unor indicatori ai resurselor umane din sănătate, 1969-2009

Anul	Nr. mediu de locuitori ce revin la un:			
	Medic*	Stomatolog	Farmacist	Asistent medical
1969	774	5535	4410	211
1974	762	3655	3996	179
1979	705	3247	3553	168
1984	580	3113	3471	171
1989	552	3253	3599	171
1994	567	3844	8078	175
1999	523	2914	3398	197
2004	450	2188	2473	178
2009	426	1718	1790	166

**exclusiv stomatologi*

Statisticile oficiale evidențiază că la sfârşitul anului 2009, în România erau: 50.386 medici (exclusiv stomatologi), din care 12.009 medici de familie; 12.497 medici dentişti (stomatologi); 11.996 farmacişti; 129.673 asistenți medicali şi moaşe (4).

Aceasta înseamnă că, în medie, la fiecare 10.000 locuitori există: 23,5 medici (exclusiv stomatologi); 5,8 medici dentişti (stomatologi); 5,6 farmacişti; 60,4 asistenți medicali şi moaşe.

În prezent, România, comparativ cu alte țări europene, se confruntă cu un deficit de resurse umane, deşi chiar în rândul țărilor industrializate există mari diferențe în ce priveşte indicatorii respectivi de evaluare (5) (tab. II).

Comparativ cu România (23,5 medici/10.000 locuitori), în majoritatea țărilor vest europene, indicele de asigurare cu medici depăşeşte media Uniunii Europene de 32,8, existând unele țări cu peste 40 medici/10.000 locuitori. Pentru asistenții medicali şi moaşe, media Uniunii Europene este de 108,5/10.000 locuitori (din care 79,4 asistenții medicali şi 29,1 moaşe), valori ce contrastează cu cele din România (6).

Libera circulație a forței de muncă şi-a făcut resimțit efectul şi în România, odată cu aderarea la Uniunea Europeană, după care migrația forței de muncă din sănătate a devenit o problemă majoră cu care se confruntă sistemul de sănătate, fiind afectată funcționarea normală şi calitatea serviciilor.

După 1 ianuarie 2007, diploma care atestă pregătirea personalului medical este recunoscută în spațiul UE, iar Ministerul Sănătății eliberează, la cerere, un certificat pentru recunoaşterea diplomei medicilor, asistentelor şi moaşelor. În intervalul 2007-2010, aproximativ 9.000 de medici au obținut certificatele de conformitate pentru a putea munci în străinătate, din aceştia 8000 fiind plecați deja (7,8).

TABELUL II

Resursele umane din domeniul sănătății în unele țări industrializate

Țara	Nr. resurse umane/ 10.000 locuitori	
	Medici	Asistente şi moaşe
Australia	25	97
Austria	37	66
Belgia	42	142
Canada	19	101
Danemarca	36	101
Elveția	40	110
Franța	34	80
Germania	34	80
Grecia	50	36
Irlanda	29	195
Israel	37	62
Italia	37	72
Japonia	21	95
Marea Britanie	23	128
Norvegia	38	162
Spania	33	76
Statele Unite	26	94

Numai în cursul anului 2010, un număr de 2779 de medici au solicitat certificate profesionale curente. Cele mai mari valori au fost înregistrate în Bucureşti – 947, urmat de Cluj – 403, Iaşi – 253 şi Timiş – 202 (8).

Acest fenomen corelat cu intrarea României în Uniunea Europeană, a fost observat în toate țările din Europa de Est şi în multe țări din Europa Occidentală (9).

Un studiu efectuat pe un eşantion reprezentativ la nivel național de asistente medicale, a evidențiat profilul asistentului medical din România, cu un înalt potențial de migrare, astfel: asistent medical generalist, absolvent al unui colegiu de asistenți medicali, cu vârsta cuprinsă între 26 - 35 de ani, care locuieşte într-o zonă urbană, în partea nord-estică sau sudică a țării (10).

Intenția de emigrare a unor cadre medicale este "susținută" şi de faptul că firmele de recrutare din domeniu şi-au intensificat activitatea în ultimii ani, organizând numai în toamna anului 2010 patru ediții (Cluj, Timişoara, Iaşi, Bucureşti) ale Târgului Internațional de Cariere Medicale şi Farmaceutice. Oferta a fost pentru țări ca Marea Britanie, Irlanda, Germania, Suedia, Danemarca, Franța, Elveția, Belgia, Norvegia sau Spania, cele mai mici salarii oferite fiind cuprinse între 80.000 – 120.0000 euro pe an, pentru medicii cu experiență existând şi şansa de a câştiga între 150.000-200.000 euro pe an (11).

Firmele care fac recrutări oferă medicilor cursuri de pregătire, o primă de instalare, dar şi facilități de angajare pentru soții sau soțiile lor, fiind solicitați, în special, medici generalişti, anestezişti şi oncologi. În anul 2010 cele mai multe cereri de certificate profesionale curente au fost pentru specialitatea de medicină generală/ medicină de familie, urmând chirurgia generală şi anestezie şi terapie intensivă.

CONSECINȚE ŞI PERSPECTIVE

Într-un Raport al Comisiei Prezidențiale pentru analiza şi elaborarea politicilor din domeniul sănătății publice din România, se arată că din perspectiva resurselor umane, există dezechilibre importante între diferitele regiuni ale țării. Astfel, în regiunea de Nord-Est a fost înregistrată cea mai slabă acoperire cu medici în mediul rural (2.778 locuitori/1 medic) (12).

Există încă un număr de 98 de comunități fără medic în mediul rural. Populația arondată localităților din mediul rural fără medici de familie era de 145.110 locuitori, reprezentând 1,48 % din totalul populației rurale.

Pentru o treime din teritoriul României, mai mult de 30% din specialitățile medicale nu sunt acoperite cu medici (cardiologie, medicină de urgență, terapie intensivă, diabetologie etc.); o situație similară apare şi în cazul asistentelor medicale. Acest lucru a dus la adâncirea inegalităților dintre populația rurală şi urbană sub aspectul accesului la serviciile de sănătate.

Ca urmare a posibilității personalului medical din România de a lucra în țările UE, se va asista în continuare la o reducere a densității personalului din domeniul medical, mai ales în rândul tinerilor şi a celor înalt specializați. Este de aşteptat ca structura pe vârste a medicilor de familie şi mobilitatea crescândă a forței de muncă, să supună sistemul de sănătate la presiuni considerabile.

De asemenea, în acelaşi Raport al Comisiei Prezidențiale, se arată că majoritatea medicilor de familie au vârsta cuprinsă între 45 şi 55 ani, urmând a se pensiona în 10-15 ani, şi că puțini sunt tinerii care practică medicina de familie. Dacă această tendință va continua, numărul medicilor, în general, şi al celor de familie, în special, va scădea dramatic, conducând la o scădere a accesului la îngrijiri şi creşterea cheltuielilor de funcționare a sistemului.

Analiştii economici şi financiari au elaborat prognoze conform cărora dacă se păstrează acelaşi ritm al intrărilor şi ieşirilor din sistem din ultimii doi ani, în anul 2021 nu vor mai fi medici care să lucreaze în România (13).

În prezent, media anuală a ieşirilor medicilor din sistem se ridică la 7.615 (3.333 prin migrație şi 4.282 ieşiri naturale).

La o medie anuală a intrărilor în sistem de 2.916, există în contrapondere o medie anuală a ieşirilor medicilor din sistem (prin migrație şi pensionare) de 7.615. Astfel, anual în România 4.699 de medici nu mai sunt înlocuiți, ceea ce înseamnă că raportarea la numărul total de medici din sistem înregistrat în 2009 (50.386), sugerează că, în aproximativ 11 ani, nu vor mai fi medici autohtoni care să asigure asistența pentru sănătate a populației.

CONCLUZII

Migrația forței de muncă din sănătate este un fenomen care in România a luat proporții îngrijorătoare, urmare a unui sistem de motivare insuficientă a personalului medical prin veniturile obținute, condițiile nesatisfăcătoare de muncă şi posibilitatea redusă de promovare profesională pe baza unor criterii obiective.

Principalele direcții de acțiune în vederea optimizării situației actuale a resurselor umane din sănătate sunt prezentate în Raportul Comisiei Prezidențiale privind politicile de sănătate publică (12).

1. *Elaborarea unor politici sectoriale coerente de formare, dezvoltare şi alocare a resurselor umane în sănătate.* În acest scop, Ministerul Sănătății trebuie să îşi îmbunătățească propria capacitate de analiză politică, planificare şi management de resurse umane la nivel central, concomitent

cu îmbunătățirea capacității de evaluare şi prognoză a numărului şi categoriilor/specialităților de personal adecvat, astfel încât să răspundă nevoilor de sănătate ale populației pe termen mediu şi lung.

2. *Creşterea disponibilității resurselor umane în sectorul de sănătate din România*. Este vorba de creşterea numărului de locuri în instituțiile de învățământ medical, concomitent cu limitarea pierderilor prin ieşirile din sistem. Pentru menținerea personalului factorii motivaționali trebuie corect identificați şi aplicați adecvat. Creşterea veniturilor până la atingerea unui nivel decent, ar însemna recunoaşterea imensei responsabilități a unei profesii făcute cu seriozitate şi dăruire.

3. *Stimularea dezvoltării carierei profesionale în domeniul medical.* Introducerea unui mecanism de recunoaştere şi încurajare a performanțelor profesionale şi a calității serviciilor la toate nivelurile sistemului de sănătate ar permite bun un sistem de motivare. La acesta ar contribui şi organizarea de cursuri de formare continuă pentru medici şi asistenți, în concordanță cu politicile de dezvoltare a sistemului de sănătate, neinfluențate de interesele comerciale ale distribuitorilor de medicamente sau aparatură medicală.

NECESARUL DE TRATAMENT ORTODONTIC LA STUDENŢII FACULTĂŢII DE MEDICINĂ DENTARĂ DIN IAŞI

Carina Balcoş, I. Dănilă, Iulia Săveanu
Universitatea de Medicină şi Farmacie „Gr.T. Popa" Iaşi
Facultatea de Medicină Dentară

ORTHODONTIC TREATMENT NEED OF THE STUDENTS OF THE FACULTY OF DENTAL MEDICINE FROM IASI (Abstract): Nowadays, people are becoming more aware of the importance ofaesthetics in the integration of the individual in society. The purpose of this study was to determine the need for orthodontic treatment and their aesthetic perception in agroup of medical students in Iasi. **Material and methods**. The clinical study was conducted on a sample of 254 subjects. Data were collected after completion of the clinical examination.The clinical evaluation of the status we used orthodontic index IOTN (Index Orthodontic Treatment Needs) and a questionnaire on aesthetic appreciation by the student. All subjects included in the study were informed verbally about the purpose of the study noting the consent form. Statistical data processing was done with SPSS14.00 program for Windows. **Results**: 20% of the subjects were dental IOTN 0, 33% of the value of a IOTN subjects, 28% of subjects IOTN value 2, 3 and 9% IOTN value IOTN 4and 5 values of 4% and 6% respectively. The need for orthodontic treatment is greater in subjects with IOTN 4 and 5 and 10% of the subjects presented severe dento-maxillary. IOTN aesthetic component of the index is divided into three groups: Group 1 - 4 with 91% of subjects, group 5-7 with 5% of subjects and group 8-10 with4% of subjects. **Conclusions**: The need for orthodontic treatment for subjects with IOTN4 and 5 is mare. There is an increasing number of orthodontic treatment in young people, the primary motivation being to improve the aesthetic appearance. **Key words**: IOTN, NECESSARY ORTHODONTIC TREATMENT, STUDENTS

Percepţia individului în ceea ce priveşte aspectul estetic şi integrarea socio-comportamentală a acestuia sunt factori care contribuie la motivarea pacientului în realizarea de tratamente ortodontice.

In trecut determinarea necesarului de tratament ortodontic se realiza strict din punct de vedere medical urmărindu-se prezenţa anomaliilor dentare, în prezent studiile subliniind rolul important al modului de percepţie a anomaliilor din punct de vedere estetic de către pacient, fapt ce motivează începerii acestor tratamente ortodontice. În acest scop indici precum Index of Orthodontic Treatment Need (IOTN), Dental Aesthetic Index (DAI) şi Index of Complexity Outcome and Need au fost dezvoltaţi pentru a ţine cont şi de percepŢia pacientului în ceea ce priveste anomalia dentara şi evaluarea rezultatelor tratamentului ortodontic (1,2).

IOTN este un sistem de notare al anomaliile dento-maxilare dezvoltat de Brook & Shaw (1989). Acest indice se compune din două componente independente: component dentară, care are un sistem de notare format din cinci grade de evaluare ce încadrează subiectul într-o grupă de risc în funcţie de anomaliile dentare pe care le prezintă (tab. I) şi componenta estetică care inregistrează perceptia estetica a anomaliilor dentomaxilare pe o scară de zece grade (fig.1)

Scopul acestui studiu a fost evaluarea statusului ortodontic la studenţilor medicinişti,

TABELUL 1
Componenta dentara a IOTN

IOTN 1	Ocluzie aproape perfecta
IOTN 2	Usoare anomalii dentare
IOTN 3	Anomalii dento-maxilare moderate dar care nu necesita tratamente ortodontice
IOTN 4	Anomalii dento-maxilare grave dar care necesita tratamente ortodontice
IOTN 5	Anomalii dento-maxilare foarte grave

stabilirea necesarului de tratament ortodontic dar şi percepţia acestora privind aspectul estetic al anomaliilor dento-maxilare.

MATERIAL ŞI METODĂ

Studiul a fost realizat pe 254 de subiecţi, studenti în anul II şi III la Facultăţii de Medicină Dentară, UMF Iaşi, în anul universitar 2009-2010. Lotul cuprinde 170 subiecţi de sex femenin(66.9%) şi 84 subiecţi de sex masculin(33.1%), cu o medie de vârstă de 22.7 ani(minim 21 ani, maxim 30 ani).

Datele s-au obţinut prin examenul clinic şi completarea fişei de observaţie la sediul Disciplinei de Prevenţie Oro-Dentara de către examinatori care au fost calibrati anterior.

Analiza statistica a datelor a fost realizata cu ajutorul programului informatic SPSS 14 pentru Windows.

REZULTATE

IOTN (Index Orthodontic Tretament Needs) prin cele două component IOTN dentar şi IOTN estetic subliniază necesarul de tratament ortodontic. Astfel, 20% dintre subiecţi au IOTN dentar valoarea 0, 33% dintre subiecţi IOTN valoarea 1, 28% dintre subiecţi IOTN valoarea 2, 9% IOTN valoarea 3 şi IOTN 4 şi 5 valorile de 4% şi respectiv 6%. Necesitatea realizării de tratamente ortodontice este mare în cazul subiectilor cu IOTN 4 şi 5, respective 10% dintre subiecţi prezintă anomalii dento-maxilare grave (fig.2).

Componenta estetică a indicelui IOTN se împarte în 3 grupe : grupa 1- 4 cu 91% dintre subiecţti, grupa 5-7 cu 5% dintre subiecţi şi grupa 8-10 cu 4% dintre subiecti.

Componenta estetică a indicelui IOTN se împarte în 3 grupe : grupa 1- 4 cu 91% dintre subiecţi care nu necesită tratamente ortodontice , grupa 5-7 cu 5% dintre subiecţi la care necesarul de tratament este “la graniţă” şi grupa 8-10 cu 4% dintre subiecţi care au nevoie de tratamente ortodontice complexe(fig.3).

In ceea ce priveşte tipul de anomalie dento-maxilară prezentată : 95% dintre subiecţi au prezentat anomalii dento-maxilare clasa I Angle cu uşoare anomalii dentare care nu modifică vizibil funcţional şi estetic starea pacientului şi 5% dintre subiecţi clasa aIIa Angle . Nu au existat subiecţi cu anomalie de clasa a III a Angle (fig.4).

Cele mai frecevente anomalii ortodontice semnalate au fost : anomaliile dentare izolate (89,1%), urmată de crossbite (44,5%), overbite marit (33,6%), a overjet mărit (33.6).

Situaţia tratamentelor ortodontice realizate pâna în prezent a fost următoarea : 4.3% dintre subiecţi sunt purtatori de aparate ortodontice fixe şi 2.8% de aparate mobile (aparate de contentie). 10, 6% dintre subiecţi au purtat aparate ortodontice mobile şi 7.5 % aparate fixe .

4		9	5		10	
Fig. 1. Componenta estetică a IOTN

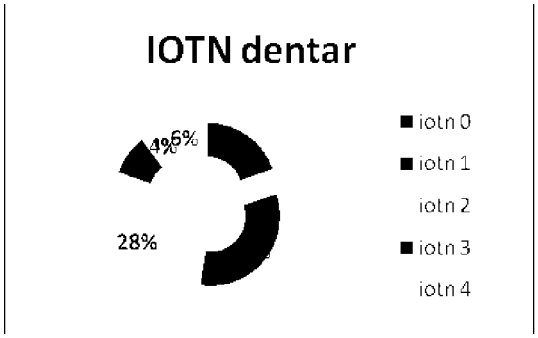

Fig. 2. Componenta dentara a IOTN-ului

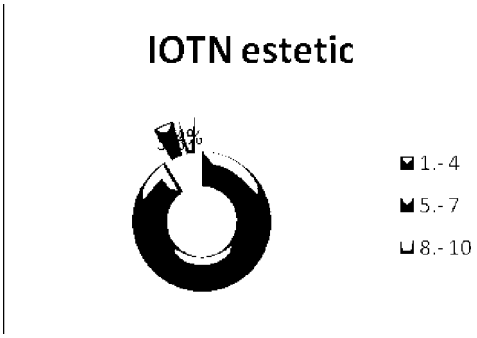

Fig. 3. Componenta estetica a IOTN-ului

La intrebarea "dacă există efecte secundare" 6% dintre subiecţi au raspuns "da", numai 80.7% declarându-se multumiţi de rezultatele tratamentelor efectuate. Subiecţii de sex femenin au fost mai nemulţumiţi de aspectul estetic în comparatie cu cei de sex masculine (p=o.o5).

Rezultatele obţinute subliniază necesarul mare de tratament ortodontic la populaţia adultă tânără din Romania, rezultate similare fiind întâlnite la populaţia tânără din Peru (3). Majoritatea studiilor epidemiologice publicate sunt realizate în populatia adultă tînără din Europa, unde tratamentul ortodontic este sustinut de către sistemul public de sănătate. In Finlanda 38.5% dintre studenţi au avut tratamente ortodontice,în Suedia 40%, Norvegia 61.5%(2), valori mari în comparatie cu cele obţinute în Romania unde aproximativ 20% dintre studenti au beneficiat de tratamente ortodontice .

CONCLUZII

Desi necesarul de tratament ortodontic

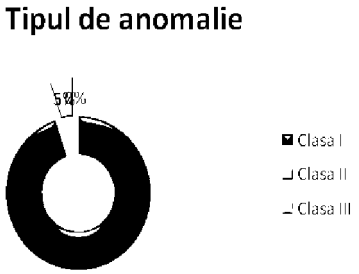

Fig. 4. Tipurile de anomalii dento maxilare

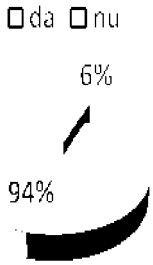

Fig. 5. Prezenţa efectelor secundare în urma tratamentului ortodontic

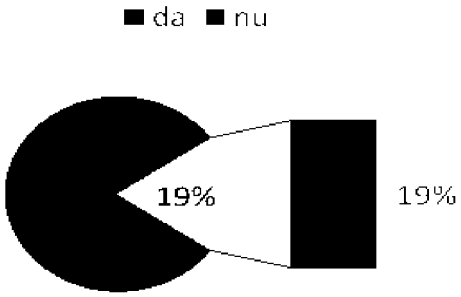

Fig. 6. Distribuţia răspunsurilor la întrebarea „Sunteţi multumiţi de rezultatele tratamentului ortodontic”

este mare la populaţia tânără se constată totuşi o creştere a numărului de tratamente ortodontice, majoritatea fiind motivate de necesitatea îmbunătăţirii aspectului estetic, componentă importantă în intergrarea socială a acestor tineri.

Procentul scăzut de tratamente ortodontice realizate la populaţia tânără este limitat din două motive : primul motiv ar fi numărul redus de medici specialişti din Romania care sunt concentraţi în oraşele mari făcând dificilă accesarea acestor servicii, iar cel de-al doilea motiv este reprezentat de susţinerea slabă a acestor tratamente de către sistemul de sănătate naţional, aceste tratamente fiind susţinute financiar în cea mai mare parte de către pacienti.

EATING HABITS IN AN ADOLESCENT POPULATION FROM TIMIŞ COUNTY (Abstract): Dietary patterns during adolescence may contribute to eating disorders and may increase the risk for several important chronic diseases later in life. **Objectives**: The aim of this study is to analyze eating behaviours among high school students residing in Timis county area. **Material and method**: We conducted a cross sectional study using a stratified cluster sample design to produce a representative sample of students for the Timis county. From 1083 primary sampling units (classes) 149 were randomly selected, stratified proportionally according to grades 9–12, high school profile (theoretical, industrial, vocational, and confessional), urban and rural environment. The study was carried out in 2004. **Results**: The overall response rate of 74.6%. A total of 2908 students were included in the survey. The proportion of students consuming less than daily milk & diary products, green salad and fruits was: 58.3% for milk & diary products, 71.2% for green salad and 59.1% for fruits. Based on multivariate analysis three common predictors for consuming fresh fruits, green salad and milk and diary products were identified: perceived weight, school performance and school grades. **Conclusions**: Through examination of prevalence rates of nutrition-related concerns we have identified priority areas to be targeted with future interventions. **Key words**: DIETARY PATTERNS, ADOLESCENTS, FOOD CONSUMPTION

Adolescence is considered an especially nutritionally vulnerable period of life for several reasons. First is the greater demand for nutrients because of the dramatic increase in physical growth and development. Second is the change of lifestyle and food habits of adolescents that affect both nutrient intake and needs. Third are those adolescents with special nutrient needs such as those who participate in sports, have a chronic illness, diet excessively, or those who use alcohol and drugs (1).

Dietary patterns during adolescence may contribute to eating disorders and may increase the risk for several important chronic diseases later in life (2,3). The main inadequate food consumption patterns are low consumption of fruits and vegetables (4,5). Dairy foods are the major source of calcium in youth diet and calcium intake is critical to achieving optimal peak bone mass and may play an important role in the prevention of degenerative bone disease in later years (6). Despite the importance of nutrition during adolescence, little is known about the eating behaviours of young people.

The aim of this study is to analyze eating behaviours among high school students residing in Timiş county area.

MATERIAL AND METHOD

We conducted a cross sectional study using a stratified cluster sample design to produce a representative sample of students for the Timis county, Romania. From 1083 primary sampling units (classes) 149 were randomly selected, stratified proportionally according to grades 9–12, high school profile (theoretical, industrial, vocational, and confessional), urban and rural environment. A 126-item questionnaire was developed to investigate health-risk behaviours of adolescents. Some of the questionnaire items were modified from other instruments, including the 1999 Youth Risk Behaviour Survey (YRBS) and the European School Survey Project on Alcohol and Other Drugs (ESPAD). The survey focused on health risk behaviours established during adolescence that result in the most significant mortality, morbidity, disability, and social problems for youths and, later, adults. The following issues were examined: family milieu, out-of-family entourage, tobacco use, alcohol use, illicit drug use, violence-related behaviours and school-related violent behaviours, suicide ideation, attempted suicides, and the seriousness of those attempts, preventive conduct in road traffic, sexual behaviours, dietary behaviours, overweight and weight control, physical activity, medical attendance. In total, 23 items were dedicated to dietary behaviours.

A pilot test was conducted to establish the validity and reliability of the instrument. The study was carried out between May–June 2004. The Timiş County Scholastic Supervision Board approved this study. The questionnaire was administered in a regular classroom setting and took students about 60 minutes to complete. No filter questions were used. By doing this, comparable amounts of time are required to complete the questionnaire, regardless of risk behaviour status and students cannot detect the risk behaviours of their colleagues simply by looking at the pattern of responses. Only students present the day of the survey were eligible for participation. Students were identified only by their classroom identification number. Trained public health residents and undergraduate students conducted the survey. The data collectors read aloud scripts that explained the survey procedures. Students were told that they do not have to put their names on answer sheets, and that obtained data would be used only for general assessment of the situation in the county and would not be ever associated with their schools or grades. A weighting factor was applied to each student record to adjust for non-response and for the varying probabilities of selection. The weights were scaled so that the weighted count of stu-

dents was equal to the total sample size.

Chi square test was used to compare categorical variables. Logistic regression modelling was used to detect predictors for certain behaviours. Using backward elimination procedures, the most parsimonious multivariate logistic regression model was produced. Odds ratios (OR) and their 95% confidence intervals (CI) were calculated. All *P* values were calculated based on two--sided statistical tests. Statistical tests were performed using Epi Info v. 3.3.2 or SPSS v.10 software.

RESULTS AND DISCUSSION

The class response rate was 97.9%, and the student response rate was 76.2%, resulting in an overall response rate of 74.6%. A total of 2908 students were included in the survey. Demographic characteristics of the sample are shown in table I.

Based on self-reported height and weight, 6.1% of students were overweight and 0.8% were obese. The overall mean (SD) body mass index (BMI) was 20.7 (2.9) kg/m^2. Male students were more likely than female students to be overweight or obese (OR= 2.0; 95%CI: 1.5-2.8).

A fundamental component of a healthy diet is to eat a balanced breakfast, which is important for nutritional adequacy. A good breakfast can contribute to a healthy diet rich in carbohydrates and micronutrients (7,8,9). We found that 9.8% of the students never eat breakfast and 34.3% rarely do. Girls were more likely than boys to skip

breakfast (OR=1.98; 95%CI: 1.53-2.57). Other studies also found more breakfast skippers among females than among males (5,10,11). In general, female and older adolescents tend to omit the morning meal. Various reasons for skipping breakfast such as lack of time or not being hungry in the morning have been observed (8,12). When it comes to frequency of eating, the highest prevalence (46.5%) is among those eating three meals each day. When asked about fresh juice intake, 34.2 % of the students responded they never drink such beverage. One third (33.0%) of the students reported eating fresh fruits between one and three times a week. Only 3.4% of the students reported never eating fruits during a week period. Green salad was consumed by 37.2% of the students between one and three times a week and never by 18.3% of the students.

The proportion of students consuming less than daily milk & diary products, green salad and fruits was: 58.3% for milk & diary products, 71.2% for green salad and 59.1% for fruits. Because of these high figures we decided to build multivariate logistic regression models to find out the most important predictors (tables II, III, IV).

Perceived weight was directly associated with inadequate consumption of fruit, green salad, milk and diary products among those who considered themselves as overweight or obese. Surprisingly, we did not find any association with body mass index.

Fruit, green salad, milk and diary products intake decreased among older adolescents in grades 11 and 12.

Students who were not satisfied with family financial situation were more likely not to eat fruit and green salad on a daily basis.

Primary school or less	0.108	1.30	0.94	1.80

Model chi-square test was 97.88 with 16 degrees of freedom ($P<0.001$).

We did not find any association between watching TV and playing computer games and low fruit and vegetables consumption as did other studies.21

No association between poor school achievement and inadequate consumption of fruits, green salad, milk and diary products was identified. Instead, we found that adolescents reporting average school marks (6-7.99) were protected against this kind of behaviour.

Students exercising to lose weight or to keep from gaining weight during the 30 days preceding the survey were more likely to eat fresh fruits less than daily (OR= 1.22; 95%CI: 1.04-1.44).

Parental educational level was related only to milk and diary products consumption, adolescents whose mothers finished vocational schools being at highest risk for inadequate consumption (OR=1.48; 95% CI: 1.12-1.95).

Assessment of dietary intake faces many problems, both related to the true nature of variation in an individual's diet and to a number of potential sources of error linked to the measurement instrument and to the reporting subject.9

Strengths of this study include the large and population-based sample of adolescents and a reasonably high response rate.

However, the study also has some limitations that should be taken into account in interpreting the findings. Although the study sample was large and diverse, it is not a nationally representative sample. Therefore, implications for other adolescent population should be made with caution. On the other hand, adolescents who gave up school were

not included in the study. Finally, body mass index was based on self-reported height and weight measures. Boys tend to overestimate their height, while girls have a tendency to underestimate their weight (13,14,15).

CONCLUSIONS

The area of nutrition may be neglected for several reasons : low priorities in comparison with other behaviours, difficulties in adequately assessing nutrition intake with a limited number of items and concerns about self-reported heights and weight (6).

Misreporting is a major problem in dietary surveys of adolescents and so all the dietary data collected should be interpreted with caution.

Through examination of prevalence rates of nutrition-related concerns we have identified priority areas to be targeted with future interventions.

We also identified three common predictors for consuming fresh fruits, green salad and milk and diary products : perceived weight, school performance and school grades.

The development of prevention programmes in school is vital as such programmes interfere with the trend of bad dietary habits among adolescent students. Associations between nutrition-related behaviours and other health behaviours indicate that eating behaviour do not occur in isolation (16,17). Interventions aimed at changes in eating behaviours should be integrated with other interventions aimed at promotion of healthy lifestyle (6). Counselling adolescents about nutrition is a true challenge. It can be very difficult to convince teenagers to modify their habits, unless they have a particular objective, are highly motivated and are capable of delaying immediate gratification for a larger future goal (2).

ACKNOWLEDGEMENT

This study is part of a type A grant financed by the National University Research Council between 2003 and 2005 (contract no.40549/2003, code 1167).

NOUTĂŢI

Cardioncologia : o nouă disciplină

Tratamentul chimioterapic este grevat de o serie de efecte adverse importante, în ultima perioadă de timp interesul îndreptându-se asupra efectelor adverse cardiace, datorită creşterii ratei de supravieţuire la pacienţii oncologici. Această creştere a supravieţuirii a adus cu sine demascarea efectelor cardiotoxice ale chimioterapiei. Se cunoaşte de multă vreme că antraciclinele au o cardiotoxicitate crecută, însă în prezent s-a demonstrat că şi noile clase de chimioterapice determină complicaţii cardiovasculare ameninţătoare de viaţă. Astfel, trastuzumabul (anticorp anti-HER2), imatinibul şi mai nou sunitinibul (inhibitor de tirozină) determină apariţia insuficienţei cardiace. Creşterea supravieţuirii pacienţilor oncologici este datorată apariţiei unei medicaţii chimioterapice eficiente, însă cu efecte adverse pe termen lung, care în mod ironic pot duce la decesul pacientului, care sunt dificil de tratat dar şi mai dificil de prevenit. Acesta este motivul pentru care s-a dezvoltat o nouă ramură medicală, cea a cardioncologiei, care este abia la început, existând puţine studii care să poată stabili care este tratamentul cardiovascular cel mai eficient în cazul pacienţilor oncologici ; aceasta deoarece marile firme de medicamente au exclus din studii pacienţii oncologici, care puteau influenţa în mod negativ supravieţuirea. Abia de curând s-au introdus în ghidurile de hipertensiune recomandări privind managementul hipertensiunii arteriale secundare tratamentului cu inhibitori de factor de creştere endotelial, precum bevacizumab (Avastin) şi sorafenib (Nexavar). În acest moment se deschide o nouă eră în tratamentul pacienţilor oncologici, în care se va putea vorbi în curând de prevenţie cardiovasculară, la un pacient aflat în remisiune sau vindecat de cancer (Mann DL, Krone RJ. Cardiac disease in cancer patients. *Prog Cardiovasc Dis* 2010 ; 53 (2) : 80-87).

OMEGA-3 FATTY ACIDS AND ACETYLCISTEINE DIET SUPPLEMENTATION EFFECTS ON LEARNING PERFORMANCE (Abstract): Omega-3 fatty acids are essential for human health, are crucial for the brain, body development and also in prevention of cardiovascular diseases. **Material and method**: We used 60 male Wistar rats, weight 180 ± 20 grams, divided into two study groups: normal control animals (M) and test animals (T) divided in groups I (N3-PUFA), II (ACC) and III (N3-PUFA and ACC). Administration of the substances was made for 36 weeks (nine months), after which the animals were evaluated and subsequently sacrificied for further biochemical analysis. As an evaluation method has been used multiple T maze labyrinth. **Results**: Group I recorded a time maze percentage decrease from -4.26% to -33.88%. In group II we recorded a decrease time maze percentage from -5.37% to -34.28%. During the experiment, group III recorded a decrease time maze percentage from -5.1% to -32.33% at the end of the experiment. The control group evolution for the maze recorded a decrease in time maze percentage, reaching 17-18% at the end of the experiment. **Conclusion**: By improving the diet with polyunsaturated fatty acids increased exponentially cognitive performance compared with normal diet, low in these acids. **Key words**: POLYUNSATURATED FATTY ACIDS, T MAZE, WISTAR RATS

Omega 3 sunt acizi graşi esenţiali pentru sănătatea umană. Omega 3 nu pot fi fabricaţi de către organismul nostru. Din acest motiv, acizii graşi omega 3 trebuie să fie obţinuti din alimentaţie sau suplimente alimentare. Acizii graşi omega-3 pot fi găsiţi în peşte (cum ar fi somon, ton sau halibut), în anumite alge şi în nuci. Acizii omega 3 mai sunt cunoscuţi şi cu denumirea de acizi graşi polinesaturaţi (PUFA) (1,2). Aceştia joacă un rol crucial pentru creier, precum şi pentru creşterea şi dezvoltarea normală a întregului organism. Există trei mari tipuri de acizi graşi omega 3, care sunt ingeraţi din alimentaţie şi utilizaţi de către organism: acid alpha-linolenic (ALA), acidul eicosapentaenoic (EPA) şi acidul docosahexaenoic (DHA). După ce mâncăm, organismul transformă ALA în EPA şi DHA, cele două tipuri de omega-3 acizi graşi mai uşor de utilizat de către corpul nostru.

Cercetările în domeniu indică faptul că, acizii graşi omega 3 reduc inflamaţiile şi ajută la prevenirea unor factori de risc asociaţi cu boli cronice cum ar fi bolile cardiace, cancerul şi de artrita. Aceşti acizi graşi esenţiali sunt foarte concentraţi în creier şi par a fi deosebit de importanţi pentru funcţia cognitivă (partea de memorie şi de performanţă intelectuală) şi funcţia de comportament (2). Copiii care nu primesc suficient omega-3 de la mamele lor în timpul sarcinii sunt expuşi riscului de a dezvolta patologii ale sistemului nervos,

deficite de vedere şi auz.

În ultimele decenii, odată cu creşterea galopantă a incidenţei bolilor cardiovasculare cu etiopatogenie aterosclerotică ce influenţează sistemul nervos central precum şi a patologiei neurodegenerative, a apărut preocuparea crescândă atât pentru cunoaşterea factorilor de risc aterogeni şi pentru îmbunătăţirea metodelor de evaluare a disfuncţiei endoteliale (element cheie în ambele stadii de evoluţie ale aterosclerozei), cât şi pentru încetinirea proceselor degenerative dar şi pentru găsirea unor noi modalităţi de prevenţie şi terapie.

Identificarea factorilor de risc favorizanţi, cât mai ales modularea factorilor cu rol protector, prin suplimente nutritive, poate avea o importanţă de prim ordin în scopul găsirii unei atitudini terapeutice pentru întârzierea sau ameliorarea bolilor sistemului nervos central şi eventual a complicaţiilor acestora (3,4,5).

MATERIAL ŞI METODĂ

În experiment au fost utilizaţi 60 de şobolani masculi, rasa Wistar, cu greutatea de 180±20 grame. Şobolanii masculi Wistar au fost împărţiţi în două grupe de studiu : animale normale martor (M) şi animale test (T).

Grupul test a fost ulterior divizat în câte trei loturi – fiecare lot fiind format din 15 animale, în raport cu tipul de substanţă administrată după cum urmează :

- Lot 1 – şobolani albi, masculi, rasa Wistar, administrare intraperitoneală de acetilcisteină (ACC) 35 mg/100 g animal ;
- Lot 2 – şobolani albi, masculi, rasa Wistar, administrare intraperitoneală de PUFA 50 mg/100 g animal ;
- Lot 3 – şobolani albi, masculi, rasa Wistar, administrare intraperitoneală de ACC 35 mg/100 g animal şi PUFA 50 mg/100 g animal ;

Grupul martor a curpins un singur lot de 15 animale care au primit doar dietă normală şi fără alte intervenţii

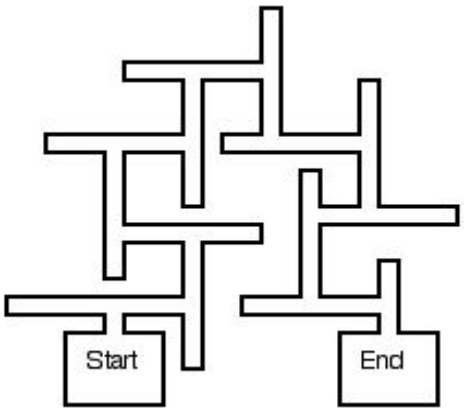

Fig. 1. Prezentare schematică a labirintului multiplu T

- Lot 4 – şobolani albi, masculi, rasa Wistar, cu dietă normală ;

Administrarea substanţelor s-a făcut timp de 36 săptămâni (9 luni), după care animalele au fost evaluate şi ulterior sacrificate.

Ca metoda de evaluare a fost folosit labirintul multiplu T. Labirintul multiplu T-este un labirint complex format din mai multe piese în formă de T. Performanţa în cadrul labirintului multiplu T este uşor de evaluat deoarece fiecare intersecţie este identică şi are un răspuns clar corect sau greşit (2,5,6). Labirintul multiplu T a fost folosit pentru a evalua răspunsul la învăţare şi elaborarea hărţilor cognitive la animalul de experienţă.

REZULTATE

Monitorizarea comportamentului în labirint a şobolanilor din Lotul I concretizat prin numărul de minute necesar traversării acestuia, pe parcursul celor 10 evaluări anterioare sacrificării, prezintă serii de valori cu varianţe ample, variind de la 10,40 CV% la a 2-a monitorizare până la 24,42 CV% la cea de a 5-a monitorizare (7,8).

La finalul experimentului, timpul necesar şobolanilor de a traversa labirintul a fost de 6,0 ori mai mic ($M_{iniţial}$ / M_{final} = 6,0), fiind semnificativ mai redus decât la

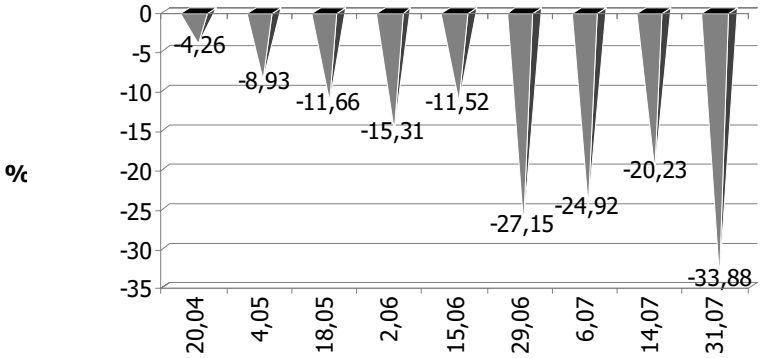

Fig. 2. Evoluţia procentuală a timpilor de labirint la lotul I pe parcursul monitorizării

debutul studiului (t= 25,24; GL= 28; p<0,001).

Pe cazuistica lotului I s-a evidenţiat o descreştere procentuală a timpului de labirint de la 4,26% până la -33,88%.

La lotul II de studiu, monitorizarea comportamentului în labirint a şobolanilor, pe parcursul celor 10 evaluări, prezintă serii de valori cu varianţe ample, variind de la 11,18 până la 23,08 CV%, cele mai omogene înregistrându-se la începutul experimentului, la a 2-a monitorizare (6).

La finalul experimentului, timpul necesar şobolanilor de a traversa labirintul a fost de 6,4 ori mai mic ($M_{iniţial}$ / M_{final} = 6,4), fiind semnificativ mai redus decât la debutul studiului (t= 19,97; GL= 28; p<0,001).

La lotul II s-a evidenţiat o descreştere procentuală a timpului de labirint de la 5,37% până la -34,28%.

La lotul III de studiu, monitorizarea comportamentului în labirint a şobolanilor, pe parcursul celor 10 evaluări anterioare sacrificării, prezintă serii de valori cu varianţe ample, variind de la 4,0 până la 21 57CV%, cele mai omogene înregistrându-se la finalul experimentului (1,7).

La finalul experimentului, timpul necesar şobolanilor de a traversa labirintul a fost de 6,2 ori mai mic ($M_{iniţial}$ / M_{final} = 6,2), fiind semnificativ mai redus decât la debutul studiului (t= 27,63; GL= 28; p<0,001).

Pe parcursul experimentului, la şobolanii din lotul III s-a observat descreşterea procentuală de la o etapă la alta a timpului de labirint până la 32,33% la sfârşitul experimentului (8,9).

La lotul martor, evaluarea comportamen-

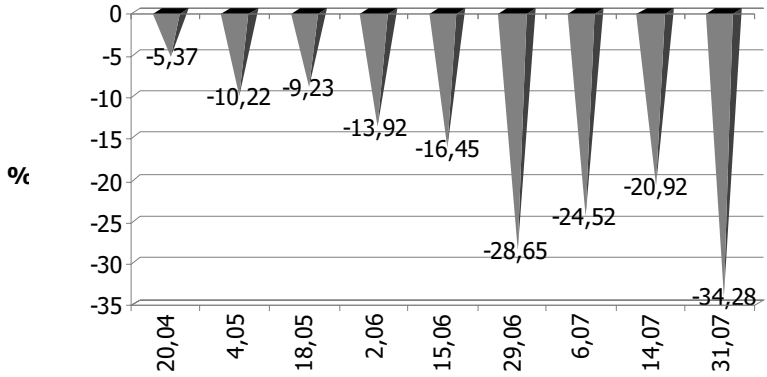

Fig. 3. Evoluţia procentuală a timpilor de labirint la lotul II pe parcursul monitorizării

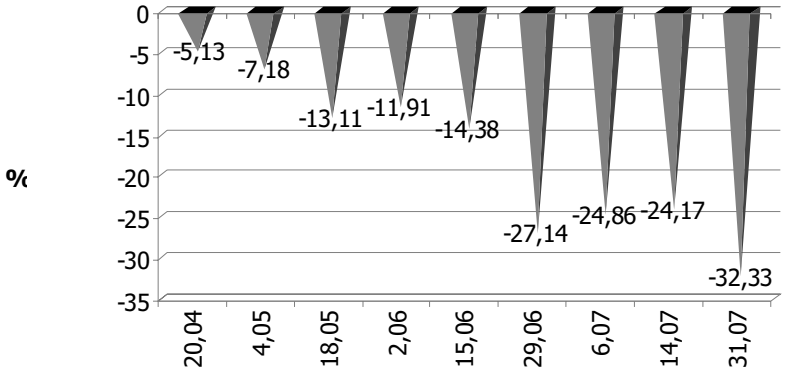

Fig. 4. Evoluţia procentuală a timpilor de labirint la lotul III pe parcursul monitorizării

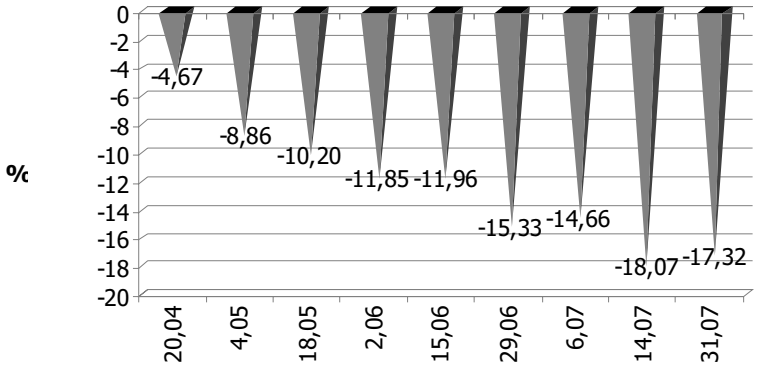

Fig. 5. Evoluţia procentuală a timpilor de labirint la lotul martor pe parcursul monitorizării

tului şobolanilor în labirint, pe parcursul celor 10 monitorizări, prezintă serii de valori cu varianţe ample, variind de la 6,73 până la 25,13 CV%, cele mai omogene înregistrându-se la a 3-a monitorizare de la debutul experimentului (7,9).

La finalul experimentului, timpul necesar şobolanilor de a traversa labirintul a fost de 3,4 ori mai mic ($M_{iniţial}$ / M_{final} = 2,8), fiind semnificativ mai redus decât la debutul studiului ($t = 27,92$; $GL = 28$; $p < 0,001$).

La lotul martor evoluţia timpilor de labirint a fost descrescătoare de la o etapă la alta, ajungând la 17-18% la finalul experimentului (10,11).

DISCUŢII

Comparând între loturi timpul de labirint se observă următoarele aspecte:

- la debutul studiului:

§ timpul mediu la labirint la lotul II, nu a prezentat diferenţe semnificative comparativ cu timpul mediu de labirint la lotul martor ($p > 0,05$);

§ animalele din loturile I ($p < 0,05$) şi III ($p < 0,001$) au prezentat diferenţe semnificative faţă de cele din lotul martor;

- la finalul experimentului:

§ timpul mediu de labirint la loturile de studiu a fost semnificativ mai mic la finalul experimentului comparativ cu cel obţinut la lotul martor ($p < 0,001$);

§ timpul mediu din lotul I nu a prezentat diferenţe semnificative comparativ cu cel obţinut la lotul II ($p > 0,05$), dar a fost semnificativ mai mare comparativ cu timpul mediu înregistrat la lotul III

($p < 0,05$) (10,11).

CONCLUZII

Cercetarea de faţă aduce un aport important în studiul acizilor graşi polinesaturaţi şi importanţa introducerii lor în alimentaţia zilnică. Astfel, prin îmbunătăţirea dietei cu acizi graşi polinesaturaţi performanţele cognitive au crescut exponenţial comparativ cu dieta normala, săracă în aceşti acizi.

Necesitatea utilizării pe scară largă a acizilor graşi polinesaturaţi este dovedită de multiplele experimente ştiinţifice, precum şi de rezultatele obţinute pe animalele de experienţă.

Studiul de faţă aduce o nouă lumină asupra importanţei existenţei unei balanţe între aportul de PUFA şi dieta zilnică.

Progresul semnificativ mai mare în cazul utilizării acestor acizi dovedeşte încă o dată necesitatea adopatării unei diete echilibrate şi bogate în nutrienţi esenţiali pentru funcţionarea organismului în condiţii optime.

POLYOMAVIRUS BK AND ITS ROLE IN ASSOCIATED KIDNEY TRANSPLANTATION PATHOLOGY (Abstract): In the last three decades kidney transplantation became a therapeutic approach in Romania but, unfortunately, the increasing of kidney transplantation procedures is related to an increasing rate of associated pathology such as Polyomavirus BK Associated Nephropathy (BKVAN). Studies published recently emphasize that BKVAN is a consequence of different risks factors, particular viral pathogenesis, humoral and cellular immunity and high doses of immunosuppressive drugs used for a long time are the main conditions that influence the BKVAN's evolution. Since there is no specific and effective treatment, optimal medical management is to diagnose nephropathy in early stages, to stop viral replication, limiting tubular lesions and prevent progress toward destruction by decreasing doses of immunosuppressive agents. **Key words**: POLYOMAVIRUS BK, NEPHROPATHY, IMMUNOSUPRESSION

EXPERIMENTAL RESEARCH FOR THE DETERMINATION OF BISOPROLOL FUMARATE IN BULK AND DOSAGE FORMS USING LIQUID CHROMATOGRAPHY

EXPERIMENTAL RESEARCH FOR THE DETERMINATION OF BISOPROLOL FUMARATE IN BULK AND DOSAGE FORMS USING LIQUID CHROMATOGRAPHY (Abstract) **Aim:** To develop a simple, economic, feasible, and effective RP-HPLC method for the quantitative determination of bisoprolol in bulk and pharmaceutical formulations. **Material and methods:** Chromatographic separation was achieved on a Zorbax SB-C18 chromatographic column. The mobile phase was a mixture of methanol and 0.02M potassium acetate (40:60) with a 1 mL/min flow rate. The UV detection was done at 225 nm. The method was validated in accordance with the current ICH guidelines in terms of linearity, limit of detection, limit of quantification, precision, accuracy, recovery, and system suitability. **Results:** The retention time for bisoprolol was 2.38 minutes. A linear response was observed over the concentration range 5-80 µg/mL of bisoprolol fumarate. The limit of detection and the limit of quantitation for bisoprolol fumarate were 1.15 and 3.81µg/mL, respectively. The precision of the method was satisfactory and the relative standard deviations did not exceed 1%. The accuracy of the method was proved and the mean recovery of drug was in the range 99.74-100.02%. **Conclusions:** The proposed method proved to be selective, simple, precise, accurate, and it was successfully applied for the determination of bisoprolol in tablets. **Keywords:** ANTIHYPERTENSIVE, BISOPROLOL, CHROMATOGRAPHIC ANALYSIS.

Bisoprolol fumarate (BF), chemically known as (±)-1-[4-[[2-(1-methylethoxy) ethoxy]methyl]phenoxy]-3-[(1-methylethyl) amino]-2-propanol(*E*)-2-butenedioate, is a synthetic, beta1-selective adrenoceptor blocking agent used in the treatment of hypertension. The two substituents present in the para position of the benzene ring might be the reason for its β1-adrenergic receptor selectivity. BF is used alone on in combination with other drugs to treat hypertension. BF is well absorbed following oral administration. The absolute bioavailability for a 10 mg dose is greater than 80%. Absorption is not influenced by meals. The first pass metabolism *of* bisoprolol fumarate is less than 20% and it is eliminated through renal and non-renal pathways, as about 50% of the dose is found unchanged in the urine and the remainder is eliminated as inactive metabolites (1-3).

Chemical analysis methods are widely used in pharmaceutical practice to ensure

the quality and safety of drugs. Quality control should be achieved through faster, more reliable and easily achievable processes. Several analytical methods for the determination of BF in bulk, dosage forms, and human plasma have been proposed, but they are devaluated by long retention times and the use of expensive chemicals (4-9). Hence, the aim of the present study was to develop a simple, economic, feasible, and effective RP-HPLC method for quantitative determination of BF in bulk and pharmaceutical formulations.

MATERIAL AND METHODS

Instrumentation and chromatographic conditions: The analysis of BF was carried out using an Agilent 1100 system equipped with a photodiode array detector. A reversed-phase HPLC column Zorbax SB-C18, 3 x 100 mm, 3.5 µm particle size was used. The column and autosampler temperature were maintained at 25°C. The chromatographic separation of BF was achieved by isocratic elution. The mobile phase used for the analysis was a mixture of methanol and 0.02M potassium acetate (40:60 v/v). A 0.45 µm membrane filter was used to filter and degas the mobile phase. The injection volume was 25 µL. The output signal was monitored and integrated at 225 nm.

Chemicals and Reagents: All solvents used were analytical grade. Milli-Q water, methanol, potassium acetate were obtained from Merck (Darmstadt, Germany). Pharmaceutical grade BF was produced by Unichem Laboratories LTD, India. Two tablet formulation of 5 mg BF (A) and 10 mg (B) were procured from the local pharmacies. Only class A standard volumetric glassware was used.

Standard solution preparation: 100 µg/mL BF standard stock solution was prepared by transferring 10 mg of BF reference standard into a 100-mL volumetric flask using 25 mL methanol. The solution was diluted up to the volume with mobile phase.

Extraction procedure for dosage forms: Twenty tablets labeled to contain 5 and 10 mg of BF were individually weighed, mixed and finely powdered. The amount of powder equivalent to one tablet was accurately weighed, transferred into 100 mL volumetric flask using the mobile phase and then sonicated for 15 minutes. The sample solution was filtered using 0.45 µm filter.

RESULTS AND DISCUSSION

To optimize the analysis method, a number of parameters (organic modifier, flow rate) have been investigated. Different mobile phases were used to achieve the best separation and resolution. BF was eluted with the optimum peak shape (fig. 1) achieved when using a mixture of methanol and 0.02M potassium acetate (40:60, v/v). The UV detection was set at 225 nm. System suitability tests, evaluating column efficiency (N), tailing factor, resolution, were done to prove that the chromatographic system was adequate for the analysis (tab. I). These tests were carried out on freshly prepared BF standard stock solutions.

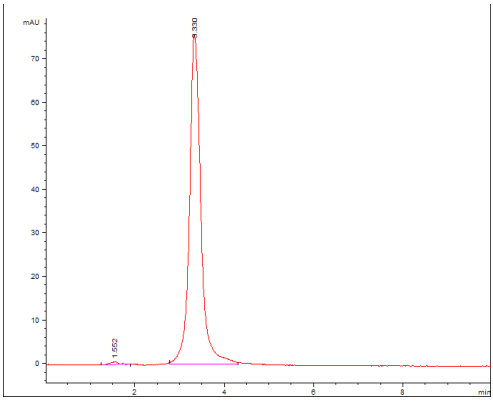

Fig. 1. Retention time of BF

TABLE I
System suitability parameters

Retention time	3.33
Area	2678
Tailing factor	1.20

Theoretical plates (N)	4210
Resolution	1.11

Linearity study: The standard stock solution was diluted to prepare three sets of BF standard solutions in the 5-80 µg/mL concentration range. Each set was analyzed to plot a calibration curve (fig. 2). To evaluate the linearity of the method (tab. II), standard deviation (SD), slope, intercept, regression coefficient (r2), limit of detection and quantification were calculated (10-12).

The precision of the method was studied for a 45 µg/mL BF solution through six replicate determinations (9). The percentage relative standard deviation (RSD%) was lower than 1.0% proving the high repeatability of the new method (tab. III).

The accuracy of the proposed method was established by means of the standard addition technique, by adding known amounts of standard substance to the 5µg/mL solution to reach three different concentration levels (25%, 100% and 125%) (10). The accuracy of the developed method for BF determination ranged from 99.74% to 100.07% (tab. IV).

As to the robustness studies, deliberate changes in the flow rate of mobile phase (± 0.2 mL/min) and column temperature (± 2°C) were made to evaluate the impact on the method. These small and deliberate variations had no significant effect on the measured system suitability parameters (tab. V).

The proposed method was successfully applied for the simultaneous determination of BF in tablets without interference from the excipients and without prior separation (tab. VI).

CONCLUSIONS

The RP-HPLC method we have developed offers various advantages, including minimal sample prepping before chromatographic separation, enough sensitivity for quantitative analysis of bisoprolol fumarate in pharmaceutical products, good precision and accuracy.

The method involves the use of easily available, inexpensive laboratory reagents and it can thus be used for routine analysis and quality control.

NEWS

STRUCTURE-BASED DESIGN, SYNTHESIS AND ANTITUMORAL EVALUATION OF ENULOSIDES

The purpose of this research is to designe and obtaine in high yields a new class of antitumoral agents with lower structural complexity. The general strategy for the synthesis of enulosides is based on the use of glycals as starting materials. From the pharmacological point of view, some synthetic enulosides exhibited activity against Mycobacterium tuberculosis H37Rv and they can also act as glycosidase inhibitors. All compounds exhibited high antitumoral activity in micromolar range against the tested tumor cell lines. (Santos JAM, Santos CS, Almeida CLA, et al. Structure-based design, synthesis and antitumoral evaluation of enulosides. *European Journal of Medicinal Chemistry* 2017, 128: 192-201).

SURVEILLANCE SEASONAL PROGRAM. ANTIBIOTIC RESISTANCE OF PATHOGENIC AGENTS ISOLATED FROM CHILDREN WITH ACUTE GASTROENTERITIS, IN A REGION OF NORTH-EAST ROMANIA (ABSTRACT): The acute gastroenteritis is a population health problem, frequently met everywhere in the world. In Romania, for certain etiologies the reporting is compulsory. Also, these infections are reported in the TESSy system, too *(The European Surveillance System)*. In this context, antibiotics therapy and antibiotics resistance have a particular importance. The study **aim** was to assess the prevalence of bacterial pathogens involved in the etiology of acute gastroenteritis (AGE) on the Iaşi County, Romania and the surrounding areas and the determination of the profile of resistance to the antibiotics for the identified agents. **Material and methods**: 72 strains of isolated and identified bacterial agents involved in the acute gastroenteritis (AGE) in the case of children (0-14 years), with the exception of the *Campylobacter spp*., in the municipality of Iasi and its surrounding areas were studied in 2012, during the surveillance period of AGE (May to October). **Results**: The most frequent has been the *Salmonella spp.* (63.9%) from which the *S. enterica Thyphimurium* in 21 cases (29.2%) and *S. enteritidis* in 7 cases (9.7%), followed by *E. coli* (20.8%) from which *E. coli* O:127 in 3 cases (4.2%), *Shigella sonnei S* (13.9%) and *Yersinia enterocolitica* (1.4%). In the case of the children from the group of 0-1 year, the *Salmonella enterica Thyphimurium* has been the pathogenic agent most frequently encountered (6 cases – 29.2%), followed by *Salmonella* Colindale, *S. enteritidis*, *Shigella sonnei S*, *E. coli* O:127 registered with a frequency of 5.6%. The antibiotic resistance rates are high in the case of ampicillin (43.1%), tetracycline (31.9%), amoxicillin – clavulanic acid (26.4%), trimethoprim/ sulfametoxazole (22.2%), sulfonamides (11.1%). **Conclusions**: The antibiotic resistance rates are high in the case of ampicillin, tetracycline, amoxicillin – clavulanic acid, trimethoprim/ sulfametoxazole, sulfonamides. **Keywords**: ANTIBIOTIC RESISTANCE, SURVEILLANCE, ACUTE GASTROENTERITIS.

Acute gastroenteritis (acute diarrheal disease - AGE) is one of the most common causes of morbidity and mortality worldwide. It is estimated that AGE is among the top 5 causes of death around the world, in particular towards younger age groups in developing countries. Worldwide, data show that $1x10^9$ episodes of AGE are reported yearly, resulted in nearly 5 million deaths, mostly recorded in children under 5 years old (1). In USA, it is estimated a number of more than 170 million episodes of AGE is estimated yearly (1, 2). In Europe, AGE is a major health problem nowadays, especially in the pediatric age and, most importantly, throughout the continent. In the European region, AGE is a disease responsible for a high number of days of hospitalization, high costs and average figures of mortality, but still cannot be neglected. In 2010, the WHO database shows that the number of deaths from intestinal infectious diseases in the age group of 0-14 years range from 28 (Ukraine), 24 in France, 31 in Romania, Germany - 12, Bulgaria - 6, Poland - 4, Czech Republic – 3, but 1 death in Switzerland, Sweden or 0 in Finland (2).

Despite the real progress, evidence-based, regarding surveillance, diagnostic techniques, prevention and therapeutic methods, AGE remains a global health population problem (3).

The aim of the present study is that to assess the prevalence of bacterial pathogens involved in the etiology of acute gastroenteritis (AGE) on the territory of the municipality of Iaşi, Romania and the surrounding areas and the determination of the profile of resistance to the antibiotics for the identified agents.

MATERIAL AND METHODS

We have studied 72 strains of isolated and identified bacterial agents involved in the acute gastroenteritis in the case of children (0-14 years), with the exception of the *Campylobacter spp*., in the municipality of Iasi and its surrounding areas, during the surveillance period of AGE (May to October 2012). The isolated strains have been transported to the "I. C. Cantacuzino" Institute, Bucharest, The Reference Laboratory of enteric bacterial infections, in order to confirm the enteric agents. In the case of all the strains identified the antibiotic resistance has been tested. 15 strains of *Campylobacter* from the feces samples collected from the Pediatric sections have been isolated, identified, and tested for the antibiotic resistance in the Regional Public Health Laboratory Centre of Iasi, at the same time. The isolation of the *Campylobacter spp*. by culture is not a current practice, and these 15 strains will be the subject of a separate study.

The database was realized in the MS EXCEL program. The statistical analysis has been performed with the SPSS 20.0 software. For the comparison, the $\chi 2$ (chi-square) test has been applied. The value of p (the materiality) that reflects the probability that the difference between the analyzed variables to be random, has been considered to be higher than 0.05.

RESULTS

From the 72 strains studied, 39 (54.2%) have been isolated from male subjects and 33 (45.8%) from female subjects and the distribution on age groups has been the following: 26 cases (36.1%) for 0-1 year, 25 for 1-4 years (34.7%), 14 from 4-10 years (19.4%) and 7 children aged 10-14 years (9.7%). During the active period of surveillance (May – October), it has been observed an incidence peak in the month of July (25 cases), followed by the same value

in the months of June and August (with 21 cases), and afterwards the rate of incidence decreases in September at 2 cases, and in October no other case of acute diarrheal disease has been registered (tab. I).

Referring to the isolated strains, the most frequent has been the *Salmonella spp.* (63.9%) from which the *S. enterica Typhimurium* in 21 cases (29.2%) and *S. enteritidis* in 7 cases (9.7%), followed by *E. coli* (20.8%) from which *E. coli* O:127 in 3 cases (4.2%), *Shigella sonnei S* (13.9%) and *Yersinia enterocolitica* (1.4%).

In the case of the children from the group of 0-1 year, the *Salmonella enterica Typhimurium* has been the pathogenic agent most frequently encountered (6 cases – 29.2%), followed by *Salmonella Colindale, S. enteritidis, Shigella sonnei S, E. coli* O:127 registered with a frequency of 5.6% (tab. II).

The antibiotic resistance rates are high in the case of ampicillin (43.1%), tetracycline (31.9%), amoxicillin – clavulanic acid (26.4%), trimethoprim / sulfametoxazole (22.2%), sulfonamides (11.1%) (fig. 1).

The *Salmonella spp.* (19 strains) and *E. coli* (10 strains) present resistance to the ampicillin and just one strain of *Shigella* from among the 10 studied has been resistant to this antibiotic. The *Salmonella* (13 strains) and *E. coli* (5 strains) present resistance also to the amoxicillin – clavulanic acid.

The most of the strains are sensitive to the most of the tested antibiotics; for example, a single strain of *Salmonella* has been resistant to the gentamicin (tab. III).

Legend: AMC – amoxicillin – clavulanic acid; AM – ampicillin; C – chloramphenicol; CIP - ciprofloxacin; CTX – cefotaxime; CF- cephalotin; E – erytromycine; GM – gentamicin; K- kanamycin; NA – nalidixic acid; SXT – trimethoprim/ sulfamethoxazole; TE – tetracycline; TM – tobramycin; CAZ – ceftazidime; IMP – imipenem; TZP – piperacillin /tazobactam; *NS – statistically not significant; ** SS – statistically significant

The tests of statistical significance confirm the resistance of the *Salmonella* to ampicillin (p=0.026). For the gentamicin (p=0.039) it can be spoken about the maintenance of the sensitivity of the *Salmonella* (a single resistant strain), compared to the resistance to other antibiotics: ceftazidime – 4 resistant strains, tetracycline – 15, trimethoprim/ sulfamethoxazole – 10, piperacillin/ tazobactam – 2, nalidixic acid - 4, sulfonamides – 5. In the case of ciprofloxacin and imipenem all the strains studied have been sensitive.

DISCUSSION

Acute gastroenteritis is a population health problem frequently met worldwide, responsible for higher levels of morbidity and even for mortality especially in the cases of the extremes of age and of the persons with a compromised immunity and especially in the developing countries (4).

In Romania, the epidemiological and microbiological surveillance of AGE is passive and it is developed at the level of all the county public health departments and at those of the Bucharest municipality. For certain etiologies *(Salmonella, Shigella, Campylobacter, Yersinia* and *E. coli* - VTEC/ STEC) the reporting is compulsory. Also, these infections are reported in the TESSy system, too *(The European Surveillance System)*. The microbiological diagnosis in the case of AGE in the current context, when there is a large number of known and identifiable pathogenic agents, implies the existence of a clear working methodology and especially accessible in the current medical practice and not only in the centers of reference and in the specialized laboratories (the case *E. coli* – the diarrhea genic pathotypes or *Campylobacter* – difficult to cultivate) (5, 6, 7).

Traditionally, *E. coli* is one of the most wide-spread microorganisms resistant to the antibiotics. The antibiotic resistance of *E. coli* is worrisome, because it may determine the most frequent infections with

gram negative bacteria, and the emergence of the phenotype producer of β-lactamase on a wide spectrum, which confers resistance to the third-generation of cephalosporin is in a continuous growth in Europe. Such strains isolated from the bacteremia have also shown an increased cross resistance to the fluoroquinolones (> 80%) and to gentamicin (> 40%) (8, 9).

The resistance to the fluoroquinolones is, also, frequent among the *E. coli* strains, which overexpresses plasmid genes *FomA* and *FomB* capable to inactivate the fosfomycin by means of the phosphorylation. The *E. coli* are, also, the most frequent pathogenic agents with transmission from animals to humans. Another enterohaemorrhagic strain, *E. coli* O104: H4, has infected more than 3.800 persons in Germany, in 2011, causing 54 deaths (8, 9).

According to the ECDC report from 2012, in Romania, Bulgaria, Slovenia and Italy, among 25-50% from the isolated strains of *E. coli* are resistant to the third-generation of cephalosporin, the same resistance being acknowledged also for the fluoroquinolones, only that this one is much more extended in Europe (10).

The results of a 5-year prospective surveillance study of the resistance to the antibiotics among *Salmonella enterica* isolates and the ceftriaxone therapy among children hospitalized for acute diarrhea ranks the tetracycline (60.6%) with the highest rate of resistance, then ampicillin (46.8%) and chloramphenicol (21.6%). The ceftriaxone resistance occurs rarely (1.9%). The resistance to the ciprofloxacin (8.7%) is more important than that to ceftriaxone. In all the 56 cases studied by authors from Italy, the ceftriaxone was indicated and effective (11).

In a study performed in Turkey, the first choice option drug was changed from TMP-SMX to cefixime because of the observed resistance to the TMP-SMX reported in proportions ranging from 47.4% to 96.5% in several regions of the country. The second choice drug, ampicillin, specific in the 1987-1994 interval, it was rarely indicated during the period 1995-2002 and for the period 2003-2009 only one patient in the study received a prescription with ampicillin. The resistance to the ampicillin in this study had high resistance rates of 58.4% and even 86% but with important differences between the strains of *Shigella spp., S. flexneri* being constantly resistant. For the *S. sonnei* a different evolution was reported. After a decline in resistance to 5.7% between 1995 and 2002, the resistance was observed in approximately 31.4% of isolates from 2003 to 2009. Most *Shigella* strains are sensitive to ampicillin in Turkey. The authors concluded that a better clinical management may help to reduce the transmission of these pathogens in the general population in the future (12).

CONCLUSIONS

Our study on surveillance of the resistance to the antibiotics in a territory may provide useful data for the elaboration of hospital guides with a regional specific, so that the emergence of new resistant phenotypes should be limited and the eventual self-medication with antibiotics should be discouraged, frequently encountered in certain areas.

In the context of global travelling, the close collaboration among the epidemiologist, microbiologist and the pediatrician is essential in the surveillance of AGE, and the laboratory diagnosis has a paramount importance in this system, at the national as well as at the international level.

STRESS IN PEDIATRIC PATIENTS–THE EFFECT OF PROLONGED HOSPITALIZATION (Abstract): Long-term hospitalization emotionally impacts any patient, especially children, and is defined as a long period of time during which the patient is hospitalized and experiences isolation from his or her family, friends and home. Stressful situations trigger a nonspecific response that involves multiple physiological mechanisms. Currently, because of the complexity of these mechanisms, there are no laboratory markers that allow the quantification of the stress intensity felt by the patient. Laboratory determinations currently used in evaluating the response to stress are neuroendocrine, immunological and metabolic. The neuroendocrine system is the first to respond to stressful events. Stress stimulates the hypothalamus, leading to the release of CRH, which stimulates the pituitary gland to produce ACTH. Chronic stress directs the synthesis towards cortisol, which may lead to hypo secretion of the other adrenal steroid hormones. The hospital and the disease are stressors for children and caregivers, since stress can interfere with the normal development of young patients, affecting them in the long term. Admitting a child to hospital means interrupting his or her normal daily life and changing the environment that is familiar to him or her. Therefore, the involvement of the family doctor is very important, as many conditions can be solved by visiting his or her office and thus eliminating the need for hospitalization in a pediatric hospital. If, however, the nature of the condition requires that the child should be seen by a pediatrician, the period of hospitalization should not be much extended so as to prevent the appearance of other possible problems that might influence the child's state. **Keywords**: LONG-TERM HOSPITALIZATION, STRESS IN PEDIATRIC PATIENTS, CHROMOGRANIN A, SALIVARY ALPHA AMYLASE.

Long-term hospitalization has a significant emotional impact on any patient, and especially on pediatric patients. The concept of long-term hospitalization is defined as a period of time during which the patient is hospitalized and he or she feels and / or becomes aware of his or her isolation from family, friends and home. Long-term hospi-

talization involves not only a particular period of time, but also the moment when a person loses emotional balance. Pediatric patients are in the process of determining their own identity, and they are psychologically, emotionally and physically dependent on their family and friends. Fortunately, medical advances have increased survival rates, while decreasing mortality rates. Children go through "normal developmental stress", doubled by the negative impact that the long-term hospitalization can have on their neuropsychological, emotional and physical development (1).

Compared to adults, infants and young children are significantly influenced by the hospital environment and its adjacent factors. Children's lack of proper and full understanding of what is happening, their communication skills that are insufficiently developed to transmit their needs, as well as their emotions and experiences may often go unnoticed by caregivers. At the same time, young patients' state of anxiety increases (2).

For all patients, temporarily giving up their personal belongings, intimacy, entourage and known environment, trigger anxiety. Wearing a certain outfit during their hospital stay, sleeping in a different bed, being imposed a certain program, diet, medication, as well as going through all the tests increases stress. On top of all this, patients come into contact with many strangers; this causes them to feel deprived of almost all aspects related to their personal space. Patients find themselves in an unfamiliar environment, which is worrying for most adults, and especially for children. In addition, hospitalization has different effects on newborn patients' long-term development, compared to adolescent patients (2, 3). Infants often get scared by unexpected noises, sudden maneuvers and movements. Starting with the age of 6 months, children already have a strong attachment towards the people who take care of them (and especially towards their mothers). Separation from these people can generate a significant discomfort in young patients, leading to the fear of separation. Moreover, children begin to be afraid of strangers and of people with atypical appearance or traits they are not used to (e.g., people wearing protective masks on their face). Up to 1 year, children acquire a lot of new skills; if they are admitted to hospital for a long period of time, developmental delays may occur. They may lack the sensory stimulation that would help them develop (music, light, reading stories, playing with the people who take care of them, toys, etc.). If parents do not spend enough time with their children in hospital, the relationships between them can be affected. The development of children aged between 1-2 years may be delayed due to the fact that the time spent in hospital interferes with the activities that could help stimulate new skills. Sleep problems may occur (2, 3, 5). Dietary imbalances are a result of home routine change and stress. At this age, children are very afraid of strangers, thus the presence of nurses and doctors increases their level of anxiety. Children are irritated, frustrated and frightened because, at this age, it is hard for them to understand why they are hospitalized. For children between 2-5 years, the main negative impact is the stress of being away from everything that is familiar to them. They may exhibit phobia towards medical procedures, which are perceived like something that can hurt them; they also feel threatened, restricted, punished and tortured (1, 3). They may feel that they have done something wrong and that this is why they are in hospital. They roughly know their bodies, but their under-

standing on how the body works is far from clear to them, and this can create frustration. Language is largely developed by the age of 5 years, but children may misinterpret what they hear. Starting with the age of 2-3 years, children begin to have the conscience of the self and their fears start to become somewhat specific. In general, at this age stage, children are afraid of things or phenomena they do not understand or cannot control (3, 6). Young children have a limited understanding of the dimensions of the things surrounding them and of the relation between cause and effect, which triggers irrational fears. The fear of separation from the people who take care of them is still present at this age. Other fears that appear are the fear of large animals, of water, of the unknown and of pain. Children's active imagination and their limited ability to distinguish between real and imaginary things cause them to be afraid of real characters. Between 3 and 6 years old, children are often afraid of being left alone or getting lost from parents. They are afraid of things such as insects, darkness, noise and actions they cannot explain or they have not come across with, imaginary creatures, physical injuries, going to the doctor, thunder and lightning (3, 7). Children aged 5-12 years may experience any of the states listed above, plus the fact that, during this period, they show normal fear of doctors, needles and pain. As children learn more about the complexity of the world that surrounds them, many childhood fears disappear; yet, they are replaced by other fears. As children's social life becomes increasingly important, many fears appear which are related to their way of interacting with other children and even with adults. In addition, abstract thinking gradually begins to develop, and children's fears also "shift" from concrete to abstract things. Fears gradually shift from the present to the future and from the certain to the hypothetical or the potential (2, 6, 7). Children begin to fear that someone in the family could be hurt or die. Other fears appear, i.e. the fear of being rejected by other children or not having friends, being ridiculed, humiliated, as well as the fear of not meeting the expectations their parents or other adults (e.g. teachers) might have related to their performance (at school or in other activities) (3, 4). Other fears continue to be normal, such as the fear of doctors and of medical procedures, the fear of natural disasters and, in general, of any potentially destructive phenomenon over which the child has no control. In addition, what is new is the appearance of a certain discomfort caused by the invasion of own privacy. As children grow, they begin to understand that they are suffering from a serious illness or that something bad is happening, with major physiological consequences. Chemotherapy, medical tests, surgery, invasive maneuvers cause a constant fluctuation of the stress level in children. Some children tend to associate the restriction of movement with death, while for older children the loss of interaction represents the isolation from the processes of everyday life (5.7).

The combination between these states and the boredom caused by the interruption of the activities that children were used to doing can cause extreme rises in the levels of anxiety and stress. Some children, after being hospitalized for a long period of time, may exhibit low self-esteem and a distorted image of own body. They may feel harassed and ignored to such an extent that they end up feeling unprepared for the transition back to normality. Because of a severe diagnosis and of prolonged hospitalization, some children and adolescents may

feel incapable of keeping up with school activities; they may feel marginalized and "left behind" (3, 4, 5). Isolation and emotional regression are also serious consequences of an illness occurring in childhood. After setting the diagnosis and initiating the treatment of a serious illness, such children often tend to become more mature than their friends. At school, it is difficult for them to find friends with whom they can socialize. Their health status often limits their participation in sport activities and causes them to end certain relationships, feel lonely and emotionally isolated. In addition, their school performance declines (2, 7). Given the factors causing isolation and a bad self-image, these patients may show depressive disorders from an early age. The complexity of fears in adolescence reflects the cognitive level and the physical and mental transformations specific to this stage. Adolescents are afraid of academic failure, parents' disappointment and rejection from friends. They are also afraid they might be put in an unfavorable light or ridiculed in front of others. In addition, they are worried about physical imperfections (e.g. acne, too high or too low body weight), death, physical and emotional harassment. During this period, great emphasis is placed on physical appearance, self-image, other people's opinion about them, the feeling of belonging to a group and peers' acceptance, as well as individual performance (3, 5).

Stressful situations trigger a nonspecific response that involves multiple physiological mechanisms. Due to the complexity of these mechanisms, there are still no specific laboratory markers that allow the quantification of stress intensity experienced by the patient. Laboratory determinations currently used in evaluating the response to stress are neuroendocrine, immunological and metabolic. The neuroendocrine system is the first to respond to stressful events. Stress stimulates the hypothalamus, leading to the release of CRH (corticotropin releasing hormone), which stimulates the pituitary gland to produce ACTH (adrenocorticotropic hormone). Under the action of ACTH on the adrenal gland, adrenaline and norepinephrine are released (from medulla) along with cortisol (from cortical area) (8). Chronic stress directs the synthesis towards cortisol, which may lead to hyposecretion of the other adrenal steroid hormones.

Cortisol exerts immunosuppressive and anti-inflammatory effects. Secretion of cortisol has a circadian rhythm, with elevated levels in the morning. Cortisol levels peak 20-40 minutes after acute stressful events. Cortisol blood levels are influenced by other factors (genetic factors, obesity). Cortisol may be measured in urine, saliva and serum, but salivary cortisol is often considered a better marker. In saliva, cortisol appears mainly in free form, not bound to proteins (such as blood); it is relatively resistant to the enzymatic degradation and it is unaffected by the salivary flow concentration. In addition to that, the procedure is less invasive (9,10).

Catecholamines: adrenaline and noradrenaline are secreted by the adrenal medulla in response to the stimulation of the sympathetic nervous system. The blood peak is recorded 60 minutes after the stressful event. The measurement of catecholamine levels in saliva requires immediate processing, as catecholamines are rapidly oxidized (9).

Salivary alpha amylase represents the major salivary protein (40-50% of the total proteins) and it is considered a marker of the sympathetic nervous system activity. The determination of salivary alpha amyl-

ase has a number of advantages: the sensitivity of determination, the immediate response to stress, the diurnal variation favorable to collecting morning samples and the low cost. However, the enzyme's levels vary with age, medication, diet, intake of caffeine or alcohol, physical exercise and associated pathologies (9, 10).

Chromogranin A is a protein with a single polypeptide chain, rich in acidic amino acid residues, which belongs to a family of neuroendocrine secretory protein named cromogranins / secretogranins. These proteins are located in the secretory vesicles of the neurons and the endocrine cells. The largest amount of chromogranin A is found in the granulations of the adrenal chromaffin vesicles and of the sympathetic nervous system. Chromogranin A is considered a stress hormone and the precursor of a number of peptides with biological functions (vasostatin, pancreastatin, catestatin, parastatin) with roles in inflammations and oxidative processes. It is associated with increased sympathetic nervous system activity induced by psychological stress (11).

Submandibular salivary glands secrete Chromogranin A, making it possible for it to be measured in saliva. The correlation between blood and salivary concentrations is not yet fully understood. A circadian rhythm has been described for human subjects, with peaks around 11 pm and minimum levels around 8 am.

Salivary chromogranin A level changes faster and is more sensitive to psychological stressors compared to salivary cortisol. After the cessation of the stress factor, chromogranin levels quickly return to the basal state (12).

Cytokines. Initially, it was assumed that stress had an immunosuppressive effect, thus explaining the infections and malignancies reported in people subjected to chronic stress. Recent studies have changed the concept of stress seen as an immunosuppressive factor, considering stress as an immunomodulatory process. These studies have focused on measuring the levels of cytokines secreted by Th1 and Th2 lymphocytes. Th1 cytokines (IL-2, TNF alpha, interferon gamma) are involved in cell-mediated immunity, while Th2 (IL 4, IL 5, IL 9 IL10) are involved in the humoral-mediated immunity. Stress affects the secretion of both types of cytokines; these cytokines are involved in the pathophysiology of inflammatory diseases (rheumatoid arthritis, asthma). Studies have proved that stress does not suppress, but acts differently on the cytokines secreted by Th1 and Th2.

Acute stress events determine a decrease in Th1 levels and an increase in Th2 cytokines levels; since Th1 cytokines are involved in cell-mediated immune response, this would increase the vulnerability to viruses and bacteria. Chronic stress leads to decreased Th1 and Th2 levels. Stress hormones, especially cortisol, affects the differentiation of naive Th0 cells into Th1 and Th2 with inhibitory effects on Th1 and potentiating effects on Th2 cytokines. Glucocorticoids suppress the production of IL12 by antigen-presenting cells (IL12 is necessary for the transformation of Th0 into Th1) and decrease the expression of IL 12 receptors by T cells and natural killer lymphocytes. They prevent the production of IFN gamma by Th1 lymphocytes stimulated by IL12. Glucocorticoid hormones also induce the production of IL 4 and IL 10. Studies have reported that chronic stress may lead to low levels of cortisol. A possible explanation could be the cortisol resistance theory: high levels of cortisol determine a decrease in the number of receptors (down regulation), which leads to

the inability of the immune system to respond to chronic stress.

It is difficult to determine the levels of cytokines, because they degrade rapidly in the tissue, thus reaching the bloodstream in small amounts. Ongoing infections and exposure to allergens also influence the basal cytokine concentrations (13, 14, 15).

CONCLUSIONS

Following the evaluation of the bibliographic information, which added to our clinical experience, we have concluded that children's admission to hospital involves changing their familial and familiar environment. Both the hospital and the illness are major stressors for children as well as for their caregivers, as stress can interfere with the normal development of pediatric patients and it can affect them in the long term. Admitting a child to hospital means interrupting his or her normal daily life and changing the environment that is familiar to him or her. Therefore, the involvement of the family doctor is very important, as many conditions can be solved by visiting his or her office and thus eliminating the need for hospitalization in a pediatric hospital. If, however, the nature of the condition requires that the child should be seen by a pediatrician, the period of hospitalization should not be much extended so as to prevent the occurence of other possible problems that might influence the child's status.

MYOEPITHELIAL CELLS (MEC) OF THE SALIVARY GLANDS IN HEALTH AND TUMOURS

In many exocrine organs, the secretory end pieces and the ducts are partly covered by cells with long processes that form an interlacing network. These cells resemble smooth muscle cells in several important aspects, yet clearly are epithelial cells, and thus are referred to as myoepithelial cells (MEC). The MEC were first discovered in the breast tissue by Krause in 1865. Since then it has been observed in the terminal end pieces and ducts of most of the exocrine glands such as salivary, mammary, sweat, lacrimal and bronchial glands. The description of these cells is diverse. Various authors have described them as "spindle shaped cells", "star shaped cells" or "basket cells" until the term "myoepithelial cells" was conferred to it. Most of the authors have studied this cell in detail in the mammary glands only until it was Tamarin in 1966 that provided a vivid image of a typical acinus-associated MEC in the salivary gland. He typically described the appearance of the cell on the acinar unit as being "like an octopus sitting on a rock". These cells lie between the basal lamina of the acinar and ductal cells at the terminal portion of the salivary glands. Positive identification of salivary gland MEC on routine microscopic preparations is very difficult. Fortunately modern sophisticated microscopic techniques have resulted in a surge of new information on this cell such as exposure of MEC by chemical removal of periacinar connective tissue and basement membrane deposits. MEC have many cytoplasmic processes which embrace glandular cells. Their nuclei are localized in the cell body. Most of the cytoplasmic organelles are found in the small areas around the nucleus. The remainder of the cytoplasm is filled with filaments and vesicles which are morphologically similar to those found in smooth muscle cells. After studying the structure of MEC in detail researchers focussed on identifying the physiological functions of these cells. The function of MEC was identified by an essential term in biologic kinetics (kinesiology) which states "form defines the function". The shape of the MEC suggested that its contraction might reduce the luminal volume in glandular endpieces, and these cells may play a role in expelling secretory products from glandular endpieces to the excretory duct system which was later proved experimentally. Thus one of the chief functions of MEC was determined. Association of tumours with MEC was determined when scientists found that a variety of tumours occurred in salivary glands and breast as compared to pancreas and concluded that this was because of presence of MEC in the former two glands. In conclusion, this paper brings about a thorough description of this cell in both physiological and pathological aspects (Chitturi RT, Veeravarmal V, Nirmal RM, B. et al.Myoepithelial Cells (MEC) of the Salivary Glands in Health and Tumours. *Journal of Clinical and Diagnostic Research*. 2015 Mar, Vol-9(3): 14-18).

ANTIINFLAMMATORY ACTIVITY OF AN N, N'-DISALICYLIDENEMETHYLEN-DIAMINE-DERIVED SCHIFF BIS BASE AND ITS COPPER(II) COMPLEX. (Abstract) **Aim:** The cooper(II) complex combination of N, N'-disalicylidenemethylenediamine and the Schiff bis base were investigated for anti-inflammatory activity. **Material and methods:** *In vivo*, the anti-inflammatory activity of the metallic complex in comparison with the activity of the Schiff bis base was tested by the method of Winter and co-workers using the Levy technique. **Results and discussions:** Our study on the anti-inflammatory activity of a new Schiff bis base and its complex cooper(II) combination showed that the Schiff bis bases exhibited significant anti-inflammatory action in acute experimental inflammation when compared to the control group. The copper cation from the complex combination enhanced the anti-inflammatory effect of the Schiff bis base, the effect being stronger at doses of 10 mg/kg cooper(II) complex. **Conclusions:** The Schiff bis base and its cooper(II) complex had an anti-inflammatory effect comparable to that of indomethacin. **Keywords**: COPPER, SCHIFF BIS BASE, COMPLEX, ANTI-INFLAMMATORY ACTIVITY.

The Schiff bis base compounds represent an important class of ligands that have been extensively studied in coordination chemistry, mainly due to their simple synthesis and easy tunable steric, electronic and catalytic properties (1-6). The complex combinations of Schiff bis bases with various cations represent a class of compounds with very important properties from a chemical and biological point of view (7).

There have already been reported many complex combinations of Schiff bis bases with different cations that showed antimicrobial, anti-inflammatory and antioxidant effect (8-11).

This paper describes the evaluation of the anti-inflammatory action of a new Schiff bis base derived from N,N'-disalicylidenemethylendiamine and its copper (II) complex that was previously synthesized and characterized (10-11).

MATERIAL AND METHODS

For the study of the anti-inflammatory activity of the Schiff bis base and its cooper(II) complex (fig. 1) the following

reagents were used: carrageenan kalium salt, indomethacin and carboxymethyl cellulose purchased from Merk - Germany. The method used to test the inflammation was edema experimentally induced through carrageenan in rats (adult Wistar rats, male of 180-200 g purchased from Cantacuzino Institute - Bucharest).

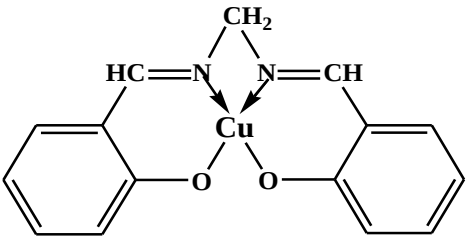

Fig. 1. Structure of cooper(II) complex combination

The evaluation of the anti-inflammatory effect was performed using the carrageenan-induced rat paw edema assay (14, 15). For each substance we used six groups of adult male Wistar rats, 180-200 g, bred in laboratory condition and identically fed. Acute inflammatory paw edema was induced by injecting 0.2 mL carrageenan 2% solution in the left posterior paw of the rat. Paw volume was determined before and after the test substance was administered and also after 1h, 2h, 4h, 6h, 8h or 24h. A control group of six Wistar received an identical carrageenan injection in order to achieve acute inflammatory paw edema, but no any other substance. Paw volume of the control group was determined at the same intervals as the test groups.

We used the following groups of rats: Group I was the control group, group II received indomethacin sodium salts 10 mg/kg i.p., group III received 10 mg/Kg of Schiff bis base, group IV received 10mg/kg cooper(II) complex and group V received 5 mg/Kg cooper(II) complex. The anti-inflammatory activity was evaluated as the variation of inflammation volume (tenths of mL). The average sum and standard deviation of that parameter were calculated for every group of rats and then they were compared to those of the control group. The obtained data were statistically analyzed using ANOVA one way test.

In *vivo*, the anti-inflammatory activity of the cooper(II) complex in comparison with that of the Schiff bis base was tested using 2% (w/v) carrageenan potassium salt solutions and 2% (w/v) indomethacin in 0.1% sodium carboxymethyl cellulose solution. The stock solutions of the complex and ligand were prepared in concentrations of 0.1% (w/v) in methanol.

RESULTS AND DISCUSSION

Several studies proved that Schiff bis bases and their complexes with various cations (Cu(II), Mg(II), Ni(II), Co(II) etc.) reduce the synthesis of some chemical mediators of acute inflammation such as leukotrienes which are involved in the formation of free radicals (9, 12, 13).

The data showed that the anti-inflammatory effect of the Schiff bis base (10 mg/kg) was statistically significant compared to the control group, after 4h ($P<0.05$). The effect increases at 6h and 8h, respectively ($P<0.001$) (tab. I).

The cooper(II) complex presented anti-inflammatory activity compared with control group, the effect being significantly stronger at a dose of 10 mg/kg, beginning with 4h ($P<0.001$). The cooper(II) complex at a dose of 5 mg/kg also presented strong anti-inflammatory effect at 4h, 6h and 8h ($P<0.001$), compared with the Schiff bis base (10 mg/kg).

TABLE I

Influence of the Schiff bis base (10mg/kg) and cooper(II) complex (10mg/kg and 5mg/kg) on carrageenan-induced inflammatory edema in rats (mean edema volume variation (tenths of mL) ± SD)

CONCLUSIONS

Our study on the anti-inflammatory activity of a new Schiff bis base and of its cooper(II) complex combination showed that the Schiff bis base exhibited significant anti-inflammatory action in acute experimental inflammation when compared to the control group.

The copper ions enhanced the anti-inflammatory effect of the Schiff bis base in its complex combination, the effect being stronger at doses of 10 mg/kg cooper(II) complex.

The Schiff bis bases and its cooper(II) complex had an anti-inflammatory effect comparable to that of indomethacin.

INFLAMMATION AND HEART DISEASES: ROLE OF TOLL-LIKE RECEPTOR SIGNALING

Myocardial inflammation is a common theme of a group of diseases that include severe sepsis, ischemic myocardial injury and acute myocarditis, and contributes to their pathogenesis. Under these critical conditions, foreign pathogens (e.g., bacteria or virus) or endogenous danger molecules (e.g., heat shock proteins [HSPs] or RNA) released from injured tissues induce local and systemic innate immune responses that lead to myocardial inflammation. Such innate immune responses could be both detrimental and beneficial in nature. Toll-like receptors (TLRs) are a critical part of human innate immune system. TLRs recognize pathogens via pathogen-associated molecular pattern (PAMP) (1) and endogenous danger molecules via danger-associated molecular pattern (DAMP) (2). TLRs also contribute to the development of inflammation in atherosclerosis that leads to myocardial ischemic injury and acute coronary syndromes. By mediating the complex cardiac inflammatory signaling, either beneficial or deleterious in nature, TLRs play a pivotal role in the development of these cardiac diseases. Several important future directions should be considered. While numerous studies have indicated the contributory role of TLRs in the development of septic cardiomyopathy, ischemic myocardial injury and myocarditis, there are many unanswered questions (including TLRs involvement in polymicrobial sepsis) that are critical for our ultimate understanding of the role of TLR signaling (Wei Chao. Inflammation and heart diseases: role of toll- like receptor signaling. J Anesth Perioper Med 2014; 1: 104-17).

ETHICAL INTERPRETATIONS OF PATIENT AUTONOMY IN CHRONIC CARE WITH SPECIAL REFERENCE TO CANCER CARE

Liana Rada Borza*, Cristina Gavrilovici

ETHICAL INTERPRETATIONS OF PATIENT AUTONOMY IN CHRONIC CARE WITH SPECIAL REFERENCE TO CANCER CARE (Abstract): The present review analyzes the ethical interpretations of patient autonomy in chronic care with special reference to the advanced cancer patient and to the transition from curative to palliative. Thus, in the context of chronic care, studies indicate that a positive conceptualization of autonomy, which is compatible with the assumption that people are interdependent, is preferred over a negative conceptualization that presents autonomy as non-interference. Moreover, it has been shown that the concept of "Socratic autonomy", which promotes an ethics of care and of interdependence, represents the standard for assessing autonomy in chronic care. With regard to cancer care, several studies illustrate that most patients decide to delegate the decisional responsibility completely to their physician and such evidence support the interpretation of autonomy as critical reflection. This paper also reviews the ethical challenges that may derive from delivering bad news to advanced cancer patients, pointing out that disclosure of a cancer diagnosis or of a poor prognosis can facilitate a so-called conspiracy of silence. **Keywords:** PATIENT AUTONOMY, CHRONIC CARE, SOCRATIC AUTONOMY, ADVANCED CANCER, CONSPIRACY OF SILENCE.

Studies note that Beauchamp and Childress' liberal individualist concept of autonomy seems to be the prevailing interpretation of autonomy in the medical literature. Stiggelbout and collaborators (1) provide, from the ethics literature, five moral alternative concepts to the one of patient autonomy defined by Beauchamp and Childress, namely, the liberal legal concept of respect for autonomy based on Berlin's negative concept of freedom, autonomy as critical reflection, actual autonomy as identification, Socratic autonomy, and autonomy as negotiated consent, but underline that "the medical literature seldom refers to these concepts of autonomy, although they are potentially of great use".

Moreover, the concept of psychological autonomy has been defined as the capacity of a person to become informed so that he/she can exercise his/her right to self-determination (2). Respect for patient autonomy can be promoted by understanding the patient's values and goals by firstly exploring patient preferences for information sharing and decision making, but also who should be involved in these processes (3).

However, Mars and collaborators (4) have emphasized that it remains unclear how the different conceptualizations of autonomy should be understood with respect to chronic diseases.

In this regard, this review explores the ethical interpretations of patient autonomy in chronic care with special reference to the advanced cancer patient and to the transition from curative to palliative care in cancer, as studies point out that cancer implies making complex and difficult decisions (5). It has also been noted that cancer-related mortality remains high, as more than 50% of cancer patients develop incurable, advanced forms of cancer, which constitute a major challenge (6).

AUTONOMY INTERPRETATIONS IN CHRONIC CARE

The liberal individualist interpretation of patient autonomy identifies autonomous decisions as those made intentionally and with substantial understanding and freedom from controlling influences (1, 7). However, Entwistle and collaborators (7) highlight the significance for autonomy of our interactions with other people and sociocultural systems, focusing on relational understandings of patient autonomy which imply that our individual capability for autonomy is socially and situationally shaped, and which thus support the value of good patient-physician relationships. In addition, Baumann (8) reconsiders the concept of relational autonomy by acknowledging the social dimension of autonomy in such a way that certain relationships and social environments can have an impact on the autonomy of a person. In this regard, Mars and collaborators (4) plead for a relational conceptualization of autonomy in the context of chronic care. The relational understandings of autonomy are thought to deemphasize independence and thus enrich the concept of autonomy (7).

The distinction between autonomy as negative liberty and autonomy as positive liberty also appears to be important in the context of chronic physical illnesses. In this regard, a negative conceptualization of autonomy seems unsatisfactory in the context of chronic care, because a person is considered autonomous if no one interferes with his/her actions. In such a context, a positive conceptualization of autonomy would be preferred, as it takes into account people's actual needs, being compatible with social models of disability and with the assumption that people are interdependent (4).

Furthermore, Naik and collaborators (9) have indicated that the nature and exercise of patient autonomy in chronic care cannot be adequately conceptualized or clinically assessed by appealing to a concept of autonomy that includes only decisional autonomy, which refers to the patient's capacity to understand information and to make voluntary decisions, pointing out the need for an expansion of the concept of patient autonomy to also include the patient's capacity to play an essential role in executing the plan of care, namely, the executive autonomy. Nevertheless, the presence of decisional autonomy with lack of executive capacity is met in the routine care and management of persons with chronic disease.

Studies also draw attention to "actual autonomy as identification", an interpretation according to which it is more important for a patient "to identify him or herself with the decision made" than to make the decision him or herself. In this view, dependence does not seem to be problematic, as identity

refers to identity as a social being in interaction with others rather than to identity as an independent being. With respect to this interpretation of autonomy in chronic care, it has been noted that "People have to integrate the course of illness into their biography", "they must reconstruct their identity, and finally, they must give their biography a new direction" (1, 4).

The "normative value", the "standard for assessing actual autonomy in chronic health care", is considered to be represented by the concept of "Socratic autonomy" which links autonomy with the fragility of human existence and patients' vulnerability by promoting an ethics of care and of interdependence, as "a human being is not only free and autonomous, but also vulnerable and dependent" (1, 10).

SPECIAL FEATURES OF ADVANCED CANCER PATIENT AUTONOMY

Decision making for cancer treatment provides challenges as it is made under high levels of distress and uncertainty and often under perceived or real time pressure (11).

Studies have outlined that telling about poor prognosis to a cancer patient may cause psychological harm to him/her (12, 13). In this regard, physicians may limit prognostic information to preserve hope. However, Mack and collaborators (14) have noted that prognostic disclosure with sensitivity and realism can sustain hope and can increase trust in the physician, even when the prognosis is poor. Thus, their study shows that honest disclosure by the physician supports patient autonomy, desire for information and abilities to make appropriate decisions. Furthermore, studies have pointed out that the breast cancer patients who were more communicatively involved in treatment decision making reported significantly less decision regret (15).

It has also been noticed that advanced cancer patients prefer to get information about their condition directly from their physician and that accepting information about imminent death would be easier if presented with sensitivity and compassion (16). Moreover, Rosner (17) emphasized that disclosure of a fatal disease diagnosis needs to be done "with compassion, sensitivity and hope thus giving the patient an opportunity to «set his house in order»".

In addition, studies underline that, when discussing a bad prognosis, the physician should firstly assess how much information the cancer patient wants to know. In this regard, the following situations have been described in the literature: the cancer patient wants to know about prognosis, but the desired amount of information varies among patients; the cancer patient does not want to know about prognosis – the right not to know has been described in the literature as "an enhancement of autonomy", being based on the idea that individuals should be free to make their own decisions (to know or not to know) with regard to information; the patient is ambivalent about knowing prognosis – the patient seems to be involved in "an ambiguous process of knowing and not knowing at the same time" (18, 19, 20, 21).

Billings & Krakauer (3) have also noted that, in order to respect patient autonomy in end-of-life care, the physician should share only as much information as the patient wishes, pointing out that forcing information or forcing decision making on a patient or family member does not promote autonomy, but it rather overrides it.

Moreover, a qualitative study on advanced cancer patients' preferences for

participation in treatment decision making has shown that all interviewed patients wanted their physician to participate in the decision making process because of his/her knowledge and clinical experience, but there were differences with regard to the extent to which patients themselves wanted to participate in treatment decision making, being emphasized that individual patients' preferences may change along with the illness trajectory (22).

A study assessing satisfaction with oncology care has also revealed that the caregivers of patients with advanced cancer seem to desire greater involvement in treatment decisions (23).

AUTONOMY AS CRITICAL REFLECTION

One of the moral concepts that has been presented in the literature as an alternative to the Beauchamp and Childress' liberal individualist concept of autonomy is the interpretation of autonomy as critical reflection, which has been defined as follows: after a critical reflection on his/her desires and preferences, the patient might decide to leave all the decisions to his/her physician (1).

In this regard, a systematic review on decision making and information provision in patients with advanced cancer has supported this interpretation by illustrating that "almost all patients expressed a desire for full information, but only about two-thirds wished to participate actively in decision making" (24).

Another study that examined the relationship between cancer patients' desire for information and their preference for participation in treatment decision making has shown that, although most of the patients actively sought information, a majority preferred the physician to assume the role of primary decision maker. Therefore, these cancer patients have chosen to express their autonomy by authorizing their physicians to make the decisions – patients "decide not to decide" (2).

Moreover, a cross-sectional study assessing Greek breast cancer patients' preferences for participation in treatment decision making and their information needs has revealed that the majority of patients wanted to play a passive role in decision making, with most of them choosing to delegate decisional responsibility completely to their physician (13).

Another study on cancer patients has emphasized that "Being freed of responsibility for making treatment decisions can produce an immense sense of relief, with treatment failures becoming the responsibility of the practitioner rather than the patient." (25, 26)

Therefore, Gessert (27) underlines that autonomy at the end of life is not universally valued by patients and their families, suggesting that "an appeal to autonomy may actually be a disservice to the peace of mind and well-being of the family".

CONSPIRACY OF SILENCE IN ONCOLOGY

It has been noted that the communication of a poor prognosis is considered one of the most difficult moments to handle in the relationship between physician and advanced cancer patient (28). Moreover, it has been pointed out that the duty of a health care professional to break bad news by giving information about disease and prognosis to terminally ill cancer patients becomes more difficult when family members ask to hold back the diagnosis from these patients (12).

Studies have emphasized that the issue of disclosure of a cancer diagnosis or of a poor prognosis facilitates a "conspiracy of silence", also known in the literature as "collusion", which is considered a universal phenomenon and which has been defined as "a secret agreement between two or more people who are trying to deceive" (29, 30). In this regard, the physician often colludes with the patient's relatives to not inform the patient about his/her diagnosis and poor prognosis, or the physician colludes with the patient to not inform the family about the patient's diagnosis and prognosis. Moreover, it has been noticed that the collusion may be complete or partial – for instance, the physician discloses the diagnosis to the patient, but withholds information about the prognosis (30). The result of withholding information from patients consists of a "false optimism" about recovery, patients becoming dominated by their recovery story and thus focusing on the present and avoiding thinking about the future. Studies also present examples of "unintentional ambiguity" generated by the physician, such as when the physician stated that "this tumor can be treated", but the patient heard that he/she can be "cured" (20).

In addition, it has been shown that close relatives frequently demand the diagnosis of malignancy to be concealed from the patients (13). Similarly, another study on cancer care highlights that a common challenge derives from the relatives seeking to avoid disclosure of bad news to patients (31). With regard to breaking bad news, it has also been noted that informing the relatives before the patient and without his/her consent still represents a common practice that can prove to be really damaging (32). It has thus been outlined that "the long-term consequences of denying patients autonomy at the end of life can be harmful to patients and can leave doctors and nurses distressed and confused" (33). Although the initial purpose is to protect a loved one from bad news, the collusive situation is observed to cause psychological suffering for all the protagonists involved (29).

Studies have thus indicated that it is important to break collusion by initiating a dialogue (29, 30). In this regard, the solution proposed at the end of an ethnographic study on patients with small lung cancer would be to implicate "treatment brokers" – people who are trusted by both the physician and the patient (20).

TRANSITION FROM CURATIVE TO PALLIATIVE CARE IN CANCER

There are only a few studies that approach the transition from curative to palliative cancer care. However, it has been noticed that, from the perspective of both patient and physician, the transition from curative to palliative is one of the most challenging phases of cancer care (34).

A study on women with advanced breast cancer has illustrated two main types of transitions: a personal transition including physical, emotional and social changes that occur over time, and a care transition reflecting shifts in cancer status, treatment and approach to care (curative, palliative or hospice care) (35).

With regard to communicating bad news in the transition from curative to palliative cancer care, studies point out that the information should be passed slowly to the patient and family without destroying hope, but also without giving false hope, and the physician should also be careful not to convey to the cancer patient a sense of

abandonment or failure (18, 34).

Another study which focused on breaking bad news in the transition from curative to palliative care in cancer has identified six types of physicians, as described by their patients, and these types have been named in a suggestive manner, as follows: "the inexperienced messenger", "the emotionally burdened", "the rough and ready expert", "the benevolent but tactless expert", "the «distanced» doctor" and "the empathic professional" (36).

Additionally, it has been indicated that the transition from curative to palliative care is a topic that often involves collusive situations (30). On the other hand, studies have emphasized that the reluctance to communicate the real situation of an incurable stage constitutes a significant barrier in implementing a transition from curative to palliative care in cancer (34, 37).

Furthermore, Jeffrey (38) outlines that a model of care based on respect for patient autonomy will allow choosing the right timing of the switch from curative to palliative care.

CONCLUSIONS

The present review provides evidence that, in the context of chronic disorders, the liberal individualist concept of autonomy has proven to be problematic, so autonomy must be re-conceptualized, the Socratic autonomy representing the normative value.

In this regard, papers on chronic care suggest that the relationship between autonomy and dependence has to be reconsidered and that these ethical concepts should not be referred to as two mutually exclusive categories.

With respect to cancer care, this review emphasizes that autonomy as critical reflection seems to be the prevailing interpretation of autonomy in several studies.

Moreover, truth telling about diagnosis and prognosis, how to break bad news, how much to tell and to whom (to the patient and/or to the relatives) represent common ethical dilemmas that health care professionals must face when interacting with advanced cancer patients.

NEWS

COPEPTIN IS AN INDEPENDENT PREDICTOR OF DIABETIC HEART DISEASE AND DEATH

It is known that high copeptin is associated with incidence of diabetes mellitus (diabetes), abdominal obesity, and albuminuria. Furthermore, copeptin predicts cardiovascular events after myocardial infarction in diabetic patients, but whether it is associated with heart disease and death in individuals without diabetes and prevalent cardiovascular disease is unknown. Vasopressin (AVP), also called antidiuretic hormone, is a peptide involved in diverse physiological functions and released from the posterior pituitary gland in conditions of decreased blood volume or high plasma osmolality. Vasopressin exerts its antidiuretic effects through the AVP 2 receptor in the kidney. The AVP 1a receptor is involved in blood platelet aggregation and vasoconstriction in the vessels and gluconeogenesis and glycogenolysis in the liver, whereas the AVP 1b receptor is found in the anterior hypophysis and the Langerhans islets of the pancreas, where it mediate secretion of adrenocorticotrophic hormone, insulin, and glucagon. Thus, AVP may affect glucose metabolism through several different mechanisms. Vasopressin is a small, short-lived peptide, and most assays measuring AVP have relatively limited sensitivity. An assay has been developed to measure plasma copeptin (copeptin), the C-terminal portion of the AVP precursor. Copeptin is considered to be a stable, reliable, and clinically useful surrogate marker for AVP. Recently, was found elevated copeptin to be associated with incident diabetes mellitus (diabetes) independently of a range of different clinically used diabetes risk factors including plasma glucose and insulin, as well as independently associated with incident abdominal obesity. Furthermore, copeptin is proposed as a useful biomarker in cardiovascular and renal disease, and is suggested to contribute to the progression and predict prognosis in heart failure (HF) and to predict prognosis in stroke and myocardial infarction. However, it is not known whether copeptin predicts heart disease or death in unselected diabetic and nondiabetic individuals in the population. Based on the previous findings that copeptin predicts diabetes, and its predictive role in diabetes patients with hemodialysis and myocardial infarction, the authors hypothesized that elevated copeptin predicts coronary artery disease (CAD), HF, and death differentially in individuals with diabetes and individuals without diabetes. The results suggested that copeptin is a promising prognostic marker for diabetic heart disease and death. Furthermore, the pharmacologically modifiable AVP system may be a new therapeutic target in the prevention of secondary diseases and premature death among individuals with diabetes (Enhörning S, Hedblad B, Nilsson PM, et al. Copeptin is an independent predictor of diabetic heart disease and death. Am Heart J 2015;169:549-556.e1).

RETROSPECTIVE EPIDEMIOLOGIC RESEARCH ON PREVALENCE OF INFECTIONS IN SURGICALLY TREATED ONCOLOGIC PATIENTS (Abstract): The **aim** of this work was the retrospective study of the frequency of infections in surgically treated oncologic patients. **Material and methods:** Our research included 753 oncologic patients treated at the Second Surgical Clinic of the Regional Institute of Oncology, Iaşi, between January 2013 and December 2014, with the selection of cases which had infectious complications. **Results:** The lot of patients was structured in 7 age groups and the most frequent oncologic patients had ages between 60-79 years. The most frequent malignancies were large bowel, breast, rectal, esophageal cancers, malignant hemopathies, gastric and liver malignant tumors. In our lot of 753 oncologic patients we depicted 113 (15.01%) infections. **Conclusions:** Our study proved that the anatomic location of the cancer, the hospitalization duration and the number of the hospitalizations has an important role in appearance of the infectious complications. The gastrointestinal malignant tumors were the most frequent malignancies associated with postoperative infections. The patients with gastrointestinal cancers from urban area, with ages between 50 and 79 years had the highest risk of infectious complications. For main causative organism was proved a high sensitivity for colistin. Clinical, paraclinical and epidemiological exams did not emphasize any decisive factors; we took into account the risks of infection during multiple pre-, intra- and postoperative procedures; all these have been associated with increased receptivity of immunosuppressed oncologic patients. **Keywords**: INFECTION, ONCOLOGY, EPIDEMIOLOGY, GASTROINTESTINAL NEOPLASM.

Oncologic pathology produces severe changes in patient's life; the immunosuppression associated with the malignancy favors the infections with various germs, the most dangerous of all being the ones given by organisms with high aggressiveness (1, 2). For oncologic patients with advanced disease, the most frequent complication with vital risk and the main cause of death are the infectious complications

(3, 4). The causative organisms determining the infections in case of patients with cancer are the opportunist organisms. The risk of selection of antibiotic resistant germs increases along with the hospitalisation duration and antibiotherapy (5, 6). The risk factors which favor the infections of an immunocompromised host are the dysfunctions of the immune system, neutropaenia, misbalances of central nervous system, the obstructive phenomena, medical invasive maneuvers, splenectomy, dysbacteriosis and the presence of microorganisms (7, 8).

MATERIAL AND METHODS

Our research included 753 patients with malignancies (354 in 2013 and 399 in 2014), treated at Second Surgical Clinic of the Regional Institute of Oncology, Iaşi, between January 2013 and December 2014. The information was obtained in collaboration with the Department of Prevention and Control of Nosocomial Infections and by studying the registers containing surgical protocols. The data were processed and interpreted with epidemiologic (prevalence, inquiry), statistic and computerized methods In order to calculate the quantitative differences we used $\chi 2$, p and t-student tests. The linear regression was calculated with the following formula y=a+bx and had underlined the evolution of the phenomenon.

RESULTS AND DISCUSSION

The distribution according to the age groups. The lot of patients was structured on 7 age groups: 20-29 years (13 patients, 1.72%), 30-39 (32; 4.24%), 40-49 (76; 10.09%), 50-59 (169; 22.44%), 60-69 (256; 33.99%), 70-79 (165; 21.91%) and over 80 (42; 5.57%) (fig. 1).

The evaluation of the oncologic patients according to the age groups. We observed that 18.06% of the patients were from the 60-64 years group, followed by 65-69 (15.93%) and 55-59 (14.20%), which shows the socio-economic and familial implications (fig. 2).

The structure of the lot of patients according to the gender. The differences of prevalence between the two genders were not significant ($p>0.05$), 50.19% of patients were males and 49.80% females.

According to the residence, 61.08% of patients lived in urban area and 38.91% in rural area, with a difference statistically significant ($p<0.05$). This situation can be explained by the differences of education and lack of accessibility to the medical assistance in case of the rural residents.

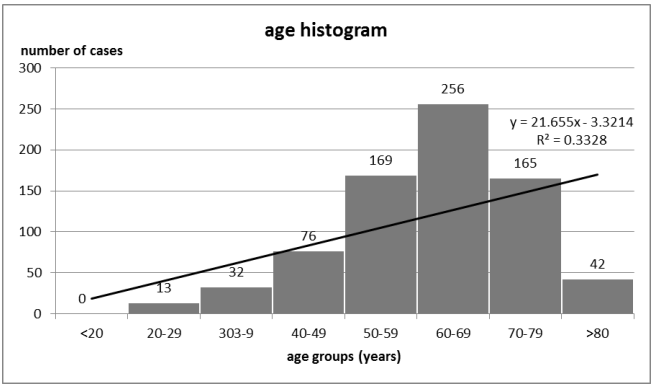

Fig. 1. The distribution by age groups of the oncologic patients included in the study

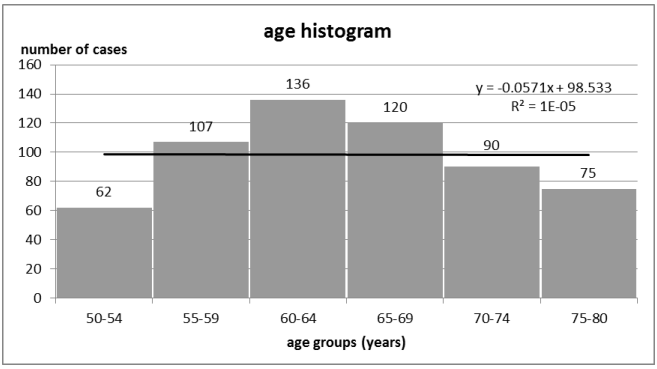

Fig. 2. The age groups distribution of the patients with frequent malignancies

Evaluation of the prevalence of certain forms of cancer. The patients we had studied had the following malignancies: large bowel (96 cases; 12.75%), breast (88 patients; 11.68%), rectum (87; 11.55%), esophagus (64; 8.49%), malignant hemopathies (59; 7.83%), gastric (55; 7.31%), liver (34; 4.51%), uterus (34; 4.51%), ovary (29; 3.85%), pancreas (27; 3.58%), skin (23; 3.05%), soft tissue (23; 3.05%), rectosigmoid (23; 3.05%), pharynx (19; 2.52%), lung (18; 2.39%) (fig. 3).

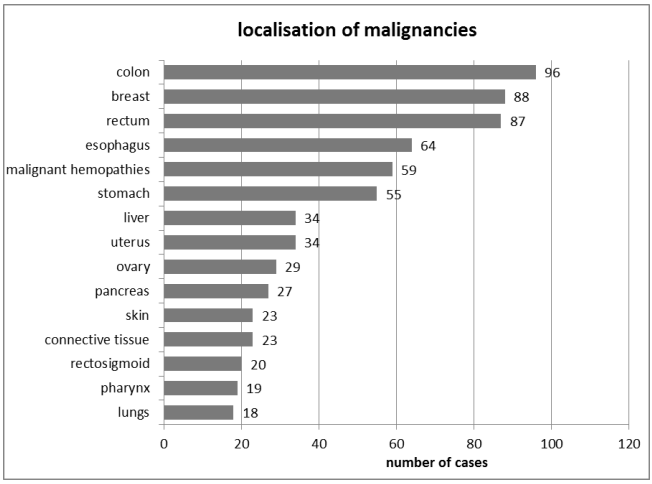

Fig. 3. The patients' distribution related to frequent malignancies

Comparing the frequency of different malignancies in 2013 and 2014, we observed a significant increase in number of various cancers in 2014: esophageal (40 cases in 2014 compared with 24 in 2013, meaning an increased percentage of 3.25%), breast malignant tumors (51 cases in 2014 compared with 37 in 2013, meaning an increased percentage of 2.33), large bowel – percentage difference of 2.20, pharynx (2.09%), thyroid (1.19%).

In 2013, we encountered some other malignancies with a higher frequency: gastric (37 cases in 2013 compared with 18

in 2014, meaning a significant percentage difference of 5. 94), malignant hemopathies (32 cases in 2013 compared with 18 in 2014, difference of 2.27%), skin - 1.70%, lung 1.35%, ovary 1.25%. In case of kidney, tongue, soft tissue, recto-sigmoid and pancreatic neoplasm we found a stationary tendency (percentage difference of less than 1) (fig. 3).

Infections encountered in case of oncologic patients. In our study, according to the literature, the infections prevalence was related to the characteristics of the primary tumor and to different co morbidities of each patient (8). The oncologic patients, secondary to immunosuppression, have an increased receptivity to various endogenous and exogenous organisms, inside and outside the hospital; the microorganisms which determine the infections are, most of the times, various species of bacteria with multiple antibiotic resistance.

Distribution of the infections related to the malignant diseases. Between January 2013 and December 2014, among the 753 patients included in the lot of study, 113 (15.01%) suffered from various infections; the most frequent of all infected patients were de ones with rectal cancers (23.0%), followed by: large bowel (16.81%), breast (11.50%), gastric (8.84%), uterine cancers (6.9%). Far less frequent were the infections appeared in case of ovary, skin, liver, biliary ducts, recto-sigmoid, lung, pharynx, esophagus, pancreatic, urinary bladder and small bowel cancers (fig. 4).

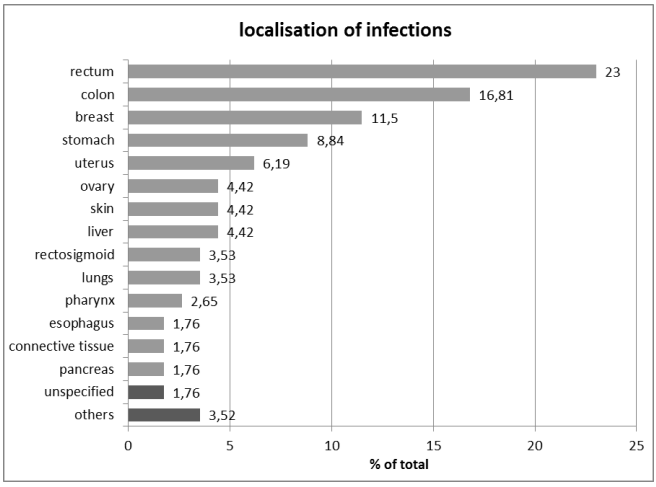

Fig. 4. Distribution of the infections related to the malignant diseases between 2013 and 2014

Mean hospitalization duration (number of days). Among the oncologic patients there was a significant difference ($p \leq 0.05$) between the mean hospitalizations duration in case of patients with infections (24.025 days) compared with those without infections (9.76 days). The hospitalization duration before surgery was longer in case of the patients with postoperative infections (5.88 days) than for the patients without infections (2.72 days), which proves that the risk of infection increases with prolonged preoperative hospitalization ($p \leq 0.05$).

Bacteria's frequency in case of oncologic patients' infections. Among the 113 patients with infections, we have encountered 204 determinations of 23 bacteria: for 63 (55.75%) cases there was only one causative organism and for 50 (44.24%) cases there were two or more causative organism; the difference among this two categories has a mean statistical significance ($p<0.05$) and can be explained by the various sites of infection and the multiple surgical procedures performed on immunosuppressed patients. The most frequent causative organism was *E. coli (*27.94%), followed by *Klebsiella pneumoniae* (18.62%), *Pseudomonas aeruginosa* (8.33%), *and Staphylococcus aureus* (7.84%). We noticed that *Staphylococcus aureus* is now on the fourth place, according to the data from the literature, standing for a decreased involvement of this bacteria community and hospital infections (fig. 5).

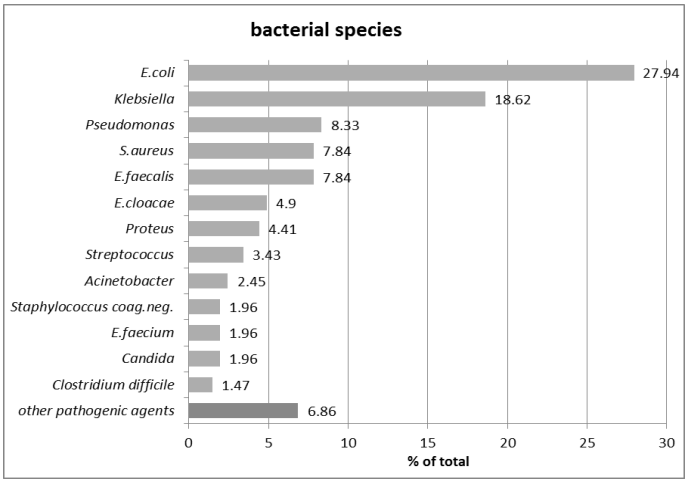

Fig. 5. Bacteria's frequency in case of oncologic patients' infections

Among the 53 cases of nosocomial infections, the most were isolated from the postoperative wounds (27: 50,95%), followed by acute enterocolitides (13: 24.53%), urinary infections (6 : 11.32%), pneumonia (5: 9.43%), and sepsis (2: 3.77%).

Causative organism observed in various biologic products. Among the 27 probes from the postoperative wounds we had isolated: *S. aureus* (33.33%), *K. pneumoniae* (14.28%) *Pseudomonas aeruginosa* (10.47%), *E. coli* (10.47%), *Enterococcus faecalis* (8.57%) and associations in other cases – 22.88% and in case of 6 positive urine cultures, *E. coli* (47.91%) and *K. pneumoniae* (27.08%) had been dominant. We had identified in haemocultures: *E. coli* and *Pseudomonas aeruginosa*; in coproculture: *Clostridium difficile*.

The interval between surgery and the occurrence of infection. The infection began during the first 48 hours in 3 cases, after 72 hours in 3, during the first week in 20, during the second week in 10, during the third week in 10, during the fourth week in 4 and in 3 cases after more than 1 month since surgery. Most of the infections appeared in the first two weeks after surgery (fig. 6).

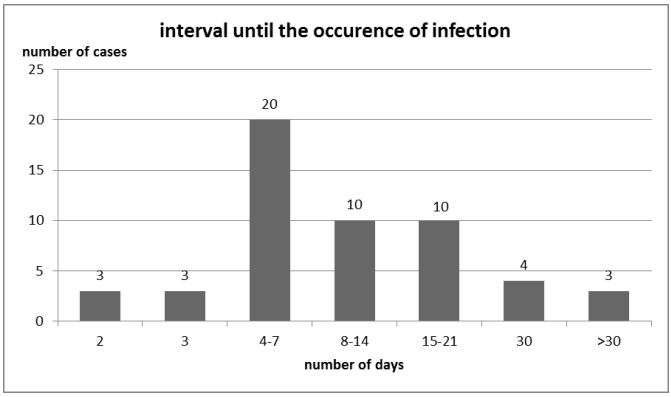

Fig. 6. The interval (days) between surgery and the occurrence of infection

The analysis of the antibiotic sensitivity of the bacteria isolated from the cultures showed the following aspects: 38 (97.43%) of 39 strains of *E. coli* had sensitivity for carbapenem (imipenem / meropenem) and all 33 (100%) strains for polypeptide (colistin); 24 (97.43%) of 33 strains of *K. pneumoniae* had sensitivity for carbapenem (imipenem/meropenem), 31 (96.87%) of 32 strains for polypeptide (colistin); 10 (83.33%) of 12 strains of *Pseudomonas aeruginosa* had sensitivity for aminoglycoside (gentamicin) and fluoroquinolone (ciprofloxacin), all 12 (100%) strains for polypeptide (colistin); all 11 strains of *S. aureus* had sensitivity for fluoroquinolone (ciprofloxacin), glycopeptide (vancomycin), sulfonamide (sulfamethoxazole), 11 (91.66%) of 12 tested strains had sensitivity for rifampicin; all 11 tested strains of *Enterococcus faecalis* had sensitivity for glycopeptide (vancomycin) and ampicillin, 10 (90.90%) of 11 strains for aminoglycoside (gentamicin). The appearance of the resistance of some strains of *K. pneumoniae* for carbapenem is of great concern. An efficient measure to limit the antibiotic multiresistance is avoiding unjustified treatments and implementing programs of good practice of antibipotherapy. *Pseudomonas aeruginosa* had resistance for most antibiotic classes because the difficulties of passing the cellular membrane; we remarked also resistance for spare antibiotics (carbapenem); 3 (27.27%) of 11 strains tested had resistance for imipenem. All tested strains of *S. aureus* had resistance for ampicillin and 50% for cephalosporines, macrolide (erythro-mycine) and tetracycline.

CONCLUSIONS

Our study showed that the anatomic location of the cancer, the hospitalization duration and the number of the hospitalizations have an important role in appearance of the infectious complications. The digestive malignant tumors were the most frequent malignancies associated with postoperative infections. The patients with digestive cancers from urban area, with ages between 50 and 79 years had the highest risk of infectious complications. For main causative organism was proved a high sensitivity for colistin. Clinical, paraclinical and epidemiological exams did not emphasize any decisive factors; we took into account the risks of infection during multiple pre-, intra- and postoperative procedures; all these have been associated with increased receptivity of immunosuppressed oncologic patients.

DEGREE OF PATIENT SATISFACTION WITH HEALTH CARE PERFORMANCE ASSESED BY MARKETING SURVEYS (Abstract): **Aim.** Marketing surveys of the health system collect useful information to develop effective management strategies. The research aim consisted in measuring patient satisfaction with health care quality. **Material and methods**. The qualitative research was based on an online SurveyMonkey open-ended questionnaire. The analysis of patient satisfaction/dissatisfaction with healthcare professionals was performed in 1838 patients. Correlation analysis allowed the identification of some determinants associated with patient satisfaction**. Results.** The variable most commonly associated with satisfaction was "I got adequate information about procedures/treatment" according to 32.2% of respondents. The patients who were dissatisfied most commonly complained that they were "Not adequately informed about maneuvers and treatment", reported by 40.0% of respondents. **Conclusions**. This study provides a basis for building an original model for determining the variables of an efficient healthcare system which to ensure a high degree of patient satisfaction. **Keywords:** PERFORMANCE, HEALTH CARE, MARKETING.

In recent years the Romanian health system takes steps toward improving the quality of healthcare services while respecting the rules underlying the accession to the European Union (EU) (1). Even in the context of important variation in health service performance, the decision makers are committed to implementing a monitoring system which is considered essential in the development of quality improvement program (2). Patient satisfaction, or health care practitioner satisfaction, respectively is one of the key criteria in quality assurance. In recent years marketing surveys have been used for assessing, among others, patient satisfaction with the quality on health care in health institutions. According to the modern marketing concept, any activity in the health system must be carried out with the knowledge of patients' needs. Thus, marketing surveys collect process and analyze information about the patients, providing evidence to support the marketing and management strategies (3).

The aim of this study was that by addressing issues of patient satisfaction to determine the necessary and useful direction in the development of management

process in health care system. The aim of this research objective was the measurement of patient satisfaction with health care performance within the context of: diagnostic characteristics, length of hospital stay, satisfaction factors and factors that could lead to dissatisfaction of patients included in the study.

MATERIAL AND METHODS

The qualitative marketing survey was based on data collected with an online SurveyMonkey questionnaire (4). For the analysis of patient satisfaction with healthcare professionals a total of 1838 subjects from university hospitals in Bucharest, Iasi, Cluj Napoca, Târgu Mures, Timisoara and Craiova were included in the study. The questionnaires included open-ended questions aimed at identifying the degree of satisfaction with the result of treatment underwent during hospital stay from both professional and medical point of view and if the patient was allowed or not to stay in touch with next of kin during hospital stays. Thus, 10 important issues were addressed: care, humanism reflected in the treatment, absence of pain, prompt attention to patient requests. Respondents' opinions on the variables that have bothered them most were expressed as 30 possible factors that contribute to a degree of dissatisfaction during hospital stay. Also, a correlative analysis was performed to identify issues that might be associated with the assessment of patient satisfaction in this study. The rate of non-responders the all questions on the questionnaire was 0.1%, not significantly influencing the quality of results. Data were processed according to the studied qualitative variables the results being considered statistically significant within a confidence interval of 95%.

RESULTS

1. Demographic and medical characteristics of the study subjects. The surveyed population was composed mostly of females (58.2%), age-group distribution showing that most subjects were in the 40-50 years (19.7%), 50-60 years (28.2%), and 60-70 years (29.5%) age-groups. Distribution of participants according to the variable "level of education", defined according to the following categories: elementary education, secondary education, post-secondary vocational education, higher education, and postgraduate education, revealed that of the surveyed population 40.6% had a higher education. The length of hospital stay was 3 days in 49.5% of the respondents, 7 days in 19.6%; 14 days in 20.0% and a maximum of 21 days in 10.7%.

2. The results of questionnaire responses in hierarchical order of their frequency were classified as follows: 1. *"I got adequate information about the procedures/treatment"* for 32.2% of respondents, but 39.1% of respondents ranked it 2nd; comparative and cumulative analysis of the results allowed the ranking of this item as 1st; 2. the variable *"I was looked after well"* according to 50.9% of respondents; 3. *"I was treated with consideration"* for 39.4% of respondents; 6. *"I was treated with warmth/kindness"*, 81.6%; 7. *"I had no pain"* according to 53% of respondents; 8. Shared by 3 variables: *"Prompt attention to all my requests"* for 38.3% of respondents, *"I had enough contact with my family"* for 33.8% of respondents and *"I had a good contact with the nursing and medical staff (they introduced themselves, joked, provided adequate psychological support)"* according to 26.6% of respondents; 9. *"I rested properly"*, 47% of respondents; 10. *"Sufficient, good quality food*" for 56.3% of

respondents (tab. I).

Based on the obtained responses the most disturbing 10 dissatisfaction factors during hospital stay in hierarchical order were the following: 1. "I did not get adequate information about the procedures/treatment" for 40.0% of respondents; 2. *"The medical staff did not introduce themselves"* according to 49.1% of respondents; 3. 45% of respondents selected the variable *"I did not know when certain procedures were to be performed";* 4. *"I was aware of odors around me"* for 44.8% of responders*;* 5. *"Mixed wards (men and women)"* according to 44.7% of respondents)"; 6. *"I was regarded as an object"* for 44.7%; 7. "*The medical staff uses words that I do not understand"* according to 45% of respondents; 8. *"In the room you are in is too cold or too hot"* in the opinion of 44.8% of respondents; 9. *"I am disturbed by the reactions of neighbor patients"* for 44.7% of respondents; 10. *"I was treated without consent"* for 35.2% of respondents.

TABLE I

Respondents' opinion on satisfaction during hospital stay

No	Treatment during hospital stay	Place/percentage of the variables that contributed to satisfaction during hospital stay									
		1	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**
1.	I was looked after well	29.7	50.9	10	8.4		1.1				0.1
2.	I was treated with warmth/kindness	0.1	0.9	0.2	16.9	0.2	81.6		0.1	0.1	
3.	I had no pain	0.2	0.2	0.2	29.6	7.6	9.3	53			
4.	Prompt attention to all my requests	0.9	0.2	22.3	0.2	18.7	0.1	19.3	38.3		
5.	I had enough contact with my family	9.9			20.3	0.3	7.6	19.6	33.8	8.4	0.1
6.	I got adequate information about the procedures/treatment	32.2	39.1	27	0.1	0.2	0.2	0.1	0.9	0.1	0.1
7.	I was treated with consideration	18.7	8.5	39.4	0.1	0.1	0.1	7.7	0.3	25.1	
8.	I had a good contact with the nursing and medical staff (they introduced themselves, joked, provided adequate psychological support)	8.4	0.2	0.1		20.3	0.1	0.1	26.6	19.2	25.1
9.	I rested properly				9.8	24.6		0.1	0.1	47	18.4
10.	Sufficient, good quality food			0.9	14.6	28		0.1		0.1	56.3

3. Correlational analysis of the results regarding patient satisfaction with health care performance showed that: "Patient age" correlates with the variables: *Appropriate care* [r (1838) = - 0.76**, p = 0.001]; *Satisfaction with how their requests were resolved* [r (1838) = 0.50*, p <0.05]; *Respect for privacy* [r (1838) = 0.72**, p <0.001] and *Fear of communicable diseases* [r (1838) = - 0.69**, p <0.001]. "Education level" was correlated with *"Perception of the level of pain experienced"* [r (1838) = 0.47*, p <0.05], and *"Modality of importance assessment"* [r (1838) = 0.53**, p <0.05].

The variable "Length of hospital stay" was strongly significantly correlated with the following variables: *Feeling that nurses are focusing more attention on devices than on patient*[r (1838) = - 0.65**, p <0.001)],

Use by the medical staff of specific medical terms [r (1838) = 0.6**, p <0.001], *Perception of ambient temperature adequacy* [r(1838) = 0.63**, p<0.001] and *Explanation of procedures/treatment* [r (1838) = - 0.75**, p <0.001]. "The level of satisfaction with the level of care received" correlates directly and inversely with the following variables: *Perception of how the patients have been treated* [r (1838) = 0.67**, p <0.001]; *Level of promptness to patient requests* [r (1838) = - 0.95**, p<0.001]; *Permission to have contact with the family* [r (1838) = 0.97**, p <0.001]; *The degree of explaining the procedures/drug treatment* [r (1838) = 0.42**, p <0.001]; *The degree of consideration with which the patient is treated"* [r (1838) = 0.321 **, p<0.001]; *Appropriate approach* (r (1838) = - 0.315**, p <0.001]; *Food quality* (r (1838) = - 0.6**, p <0.001), *Disturbed sleep* [r (1838) = - 0 5 **, p <0.001], *Brightness* [r (1838) = - 0.7 **, p <0.001]; *Degree of privacy* [r (1838) = - 0.33**, p<0.001]; *Care by unknown doctors* [r (1838) = - 0.9**, p<0.001]; *Degree of discretion* [r (1838) = - 0.32**, p <0.001] and *Fear of communicable diseases* [r (1838) = - 0.9**, p <0.001].

DISCUSSION

The results obtained allow us to state the level of satisfaction with the quality of hospital care decreases with the increasing age of patients who answered the questionnaire. We found that as the subjects were older they considered that the level of privacy was lower. Also noted was a highly significant relationship between ages and fear of communicable diseases, the older the patient the higher the fear. A relevant aspect concerns the fact that although they declared these attitudes, all subjects admitted the prompt attention to all their requests, the relationship between these variables being statistically significant. Also an increase in the number of hospital stay days was a cause of patient dissatisfaction due to the fact that nurses were more focused on devices than on patient, the patients also becoming more aware of the fact that the medical staff uses specific medical terms that patients do not understand. Also, as the length of hospital stay increased the subjects deemed inappropriate the ambient temperature and believed that they did not get appropriate information about the procedures/treatment they underwent. We believe that as the level of satisfaction with the level of care received is higher, the level of satisfaction with how the patients were treated increases, the patients believe that the procedures/treatments underwent had been clearly explained, increase the satisfaction with the consideration given and permission to be in contact with family. It was found that between the level of satisfaction with the care received and the other above mentioned variables there is an inverse relationship. Thus, as the level of satisfaction with the level of care received is higher, the level of satisfaction with the prompt attention to patient requests, the quality of contact with the medical staff, food services, quality of sleep, brightness of hospital wards, the level of privacy, and the fear of communicable diseases decrease. Also, subjects were more satisfied with the level of care received when not cared for by unknown physicians, and their right to confidentiality is not violated (5, 6, 7).

CONCLUSIONS

1. Quality of patient care largely depends on health system performance. To improve patient satisfaction a system with measurable performance goals for improved patient care should be developed.

2. A code of ethics which to take into account the results of this research is the first step in implementing a health care system. The code will be based on the above analyzed variables, complemented periodically with other variables, the research being repeated every three months.

3. The study provides a basis for the creation of an original model for determining the variables of a performant health care system, which to ensure a high degree of patient satisfaction.

NEWS

ISOQUINOLINE ALKALOIDS WITH ANTI-HEPATITIS B ACTIVITY

Hepatitis B virus (HBV) is the causative agent of B-type hepatitis in humans. Despite the fact that the disease is vaccine-preventable, about 350 million people worldwide are infected with HBV. Natural compounds are very promising for the treatment of B-type hepatitis. Eighteen isoquinoline alkaloids were isolated from sixteen *Fumaria* and six *Corydalis* species growing in Turkey. They were tested *in vitro* for anti-HBV activity using HBV-expressing cell line HepG2.2.15. Fifteen compounds showed potent anti-HBV activity in the initial screening and six of them (sibiricine acetate, berberine, α-hydrastine, oxosarcocapnidine, fumarophycine, bicuculline) demonstrated consistent antiviral activity in subsequent tests with an efficacy similar to that of tenofovir, a HBV antiviral agent. Sibiricine acetate, fumarophycine and bicuculline were more than 90-, 250- and 150-fold more potent, respectively, than tenofovir in reducing the level of HbsAg. All six compounds targeted the secretion ability of the host cell and reduced the promoter gene pSEAP secretion in a dose-dependent manner. The antiviral activity was also associated with the induction of antiviral genes; berberine and α-hydrastine induced the expression of TNF-α RNA (Aljofan M, Netter HJ, Aljarbou AN et al. Anti-hepatitis B activity of isoquinoline alkaloids of plant origin. *Arch Virol* 2014; 159: 1119–1128).

MAXILLARY SINUS ANATOMIC AND PATHOLOGIC CT FINDINGS IN EDENTULOUS PATIENTS SCHEDULED FOR SINUS AUGMENTATION (ABSTRACT) Objectives**:** An aberrant sinus anatomy or pathology can influence the sinus lift technique if it is encountered during surgical exposure. The purpose of the present study was to determine the prevalence of sinus disease and variations of normal anatomy among edentulous patients prior to sinus augmentation. **Material and methods:** 120 patients attending a private surgical practice (53 women and 67 men, with a mean age of 62.02 years, ranging between 34 and 81 years old) for whom treatment was planned for sinus augmentation were evaluated - medical history, radiographic and clinical examinations. Computerized tomograms (CT) and 3D reconstructions from 240 sinuses were analyzed using Dental CT. **Results:** Abnormalities were diagnosed in 74.2% of cases. Mucosal thickening was the most prevalent abnormality (68.3%), followed by retention cysts (15.8%) and opacification (9.2%). The diagnosed conditions included mucosal thickening, chronic sinusitis, sinus cysts and polyps. The prevalence of one or more septa per sinus was found to be 30%. Males present pathology more often than females (p=.028). No statistical correlation could be found between age and pathology (p>0.05) No significant differences in age or gender between patients with and without sinus septum were found (p>0.05). **Conclusions:** The results reinforce the importance of thorough history taking and clinical and radiographic assessment prior to performing sinus augmentation, to prevent the probability of complications. **Keywords:** SINUS DISEASE, MAXILLARY SINUS SEPTA, SINUS AUGMENTATION, COMPUTER TOMOGRAPHY

The maxilla consists of a variety of anatomic structures, including the maxillary sinus, the lateral nasal wall, the pterygoid plates, associated vasculature structures, and teeth. The maxillary sinus maintains its overall size while the posterior teeth remain in function. It is, however, well known, that the sinus expands with age, and especially when posterior teeth are lost. The average volume of a fully developed sinus is about 15 ml but may range between 4.5 and 35.2 ml. The sinus cavity expands both inferiorly and laterally, potentially invading the canine region. This phenomenon is the possible result of atrophy caused by reduced strain from occlusal function. One or more septa, termed "Underwood's septa", may divide the maxillary sinus into several recesses. The overall prevalence of one or more sinus septa is between 26.5%

and 31% and is most common in the area between the second premolar and first molar. Edentulous segments have a higher prevalence of sinus septa than dentate maxillary segments (1).

The maxillary posterior edentulous region presents more challenging conditions in implant dentistry than any other region of the jaws. However, treatment modalities have developed for this area and allow it to be predictable as any intraoral region. Most noteworthy of these treatments are subantral augmentation to increase available bone height (2).

Diseases associated with the maxillary sinuses include both intrinsic diseases (originating primarily from tissues within the sinus) and those that originate outside the sinus (most commonly diseases arising from odontogenic tissues) that either impinge on or infiltrate the sinus. These types of diseases include inflammatory odontogenic disease (thickened sinus mucosa, polyps, empyema, and retention pseudocysts), odontogenic cysts, benign and malignant odontogenic neoplasms, bone dysplasias, and trauma.

CT has become increasingly important for evaluation of sinus disease and has virtually replaced plane radiography and conventional tomography for investigations of the paranasal sinuses. Because CT provides multiple sections through the sinuses in different planes, they may contribute significantly to delineating the extent of disease and the final diagnosis. High-resolution axial and coronal CT examinations are the most revealing imaging techniques for the paranasal sinuses and the adjacent structures and areas (3).

Previous studies reported the prevalence of incidental abnormalities in CT or CBCT scan in patients' referred to as orthodontic and maxillofacial purposes, the occurrence of abnormalities is not known in samples of patients who underwent the exam for sinusal augmentation procedures (4, 5, 6, 7, 8).

The aim of the study was to determine the prevalence of sinus disease and abnormalities among edentulous patients scheduled for sinus augmentation.

MATERIAL AND METHODS

The study included 120 patients attending a private surgical practice (53 women and 67 men, with a mean age of 62.02 years, ranging between 34 and 81 years) for whom treatment was planned for sinus augmentation. The patients are edentulous in the posterior area of the maxilla. Maxillary computed tomography evaluation is performed for each patient. For statistical analysis, the subjects were divided into the following age groups: 34 – 60 and 61 - 81 years. Computerized tomograms (CT) and 3D reconstructions from 240 sinuses were assessed using Dental CT

CT was performed by using a Tomoscan SR-6000, Philips Medical Systems, Eindhoven, Holland, under the following conditions 1.5 mm slice thickness, 1 mm table feed, 120 kV, ≤25–50 mA/s, 2 s scan time/slice, 512 matrix, native and bone window.

Each observer performed all the measurements separately by using the same computer (17.3-inch diagonal HD+ Bright View LED-backlit Display (1600 x 900), HP Pavilion dv7) and screen resolution (brightness, 300 cd/ m^2; resolution, 1,920 × 1,080).

A screening procedure was engaged to identify the presence or absence of sinus abnormalities using the orthogonal views of coronal, axial and sagittal scans.

We considered deviations from normali-

ty partial or complete opacification of the maxillary sinus and increased thickening of the mucosa greater than 1 mm. We considered cases as having a sinusal abnormality when both examiners identified at least one type of abnormality and excluded cases in which both examiners diagnosed the absence of an abnormality.

The identification of an abnormality was registered separately for the right and left sinuses of each patient. Selected cases were independently reevaluated by the examiners in order to diagnose and classify the cases into different abnormality subtypes, such as: mucosal thickening, retention cysts, opacification, sinus polyps, osteoma and odontogenic cysts. The examiners noted the presence of sinus septa.

Assessment of maxillary sinus septum

Every bony prominence more than 4mm wide or 4mm high was considered because a bony prominence is thought to have an impact during elevation of the sinus floor under local anesthesia. The bony septa were transversal, horizontal, sagittal, or atypical, and were complete or incomplete (partial) (3) (fig. 1).

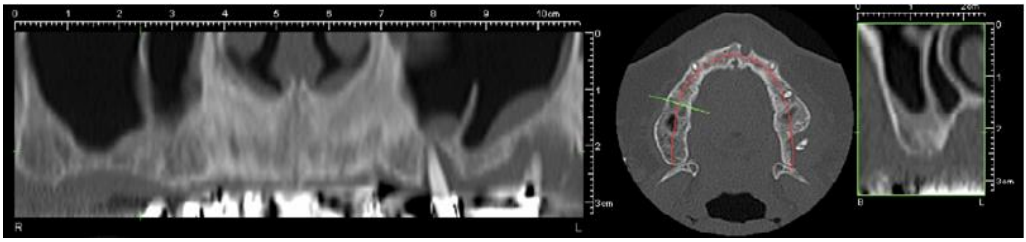

Fig. 1. Bilateral maxillary sinus septum

Assessment of pseudocysts

Whites (3) considers that pseudocysts usually form on the floor of the sinus, although some may form on the lateral walls or the roof. Retention pseudocysts may vary in size from that of a fingertip to completely filling the sinus and making it radiopaque. Retention pseudocysts usually appear as well-defined, non corticated, smooth, dome-shaped radiopaque masses. Because the lesion originates within the sinus, no osseous border surrounds it (fig. 2).

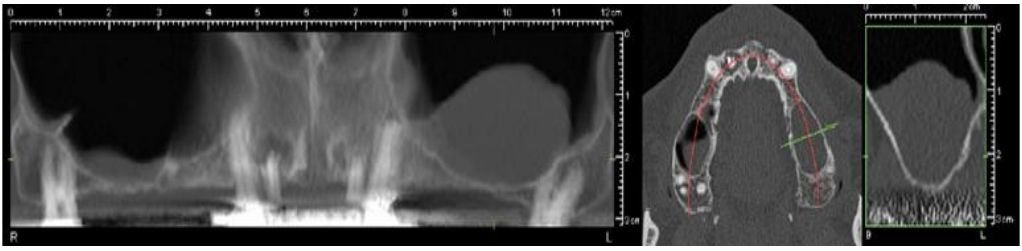

Fig. 2. Left maxillary sinus retention pseudocyst

Assessment of mucosal thickening

The image of thickened mucosa is readily detectable in the radiograph as a non corticated band noticeably more radiopaque than the air filled sinus, paralleling the bony wall of the sinus. Mucosal thickening was

considered present when the thickness of the sinus mucosa was ≥ 1 mm as measured from the floor of the sinus to the highest border of the mucosa(3) (fig. 3).

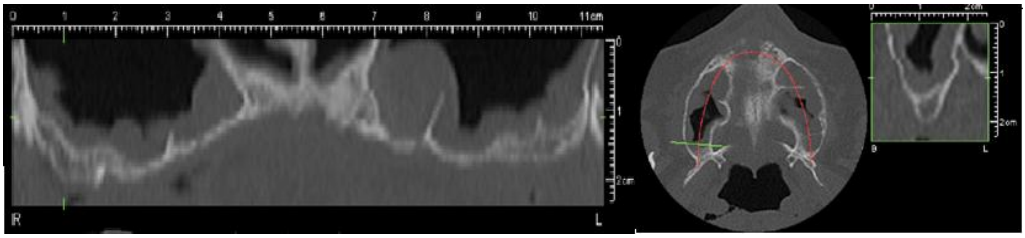

Fig. 3. Bilateral mucosal thickening of the maxillary sinuses

Assessment of sinusitis

Thickening of sinus mucosa and the accumulation of secretions that accompany sinusitis reduce the air content of the sinus and cause it to become increasingly radiopaque. The most common radiopaque patterns that occur are localized mucosal thickening along the sinus floor, generalized thickening of the mucosal lining around the entire wall of the sinus, and near-complete or complete radio opacification of the sinus (3) (fig. 4).

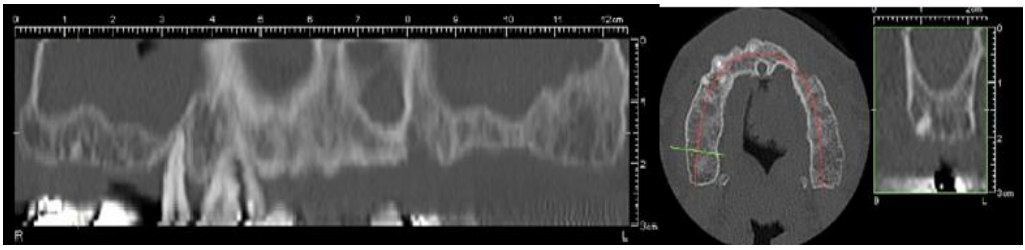

Fig. 4. Bilateral complete opacification of the maxillary sinuses

Assessment of polyps

A polyp may be differentiated from a retention pseudocyst on a radiograph by noting that a polyp usually occurs with a thickened mucous membrane lining because the polypoid mass is no more than an accentuation of the mucosal thickening. In the case of a retention pseudocyst, however, the adjacent mucous membrane lining is not usually apparent (3) (fig. 5).

Fig. 5. Polyps in the right maxillary sinus

Assessment of odontogenic cysts

The most common are radicular cysts, followed by dentigerous cysts and odontogenic keratocysts. A thin radiopaque line divides the contents of the cyst from the sinus cavity. In the case of a radicular cyst, the lamina dura of the involved tooth or teeth is not intact in the apical area (3) (fig. 6).

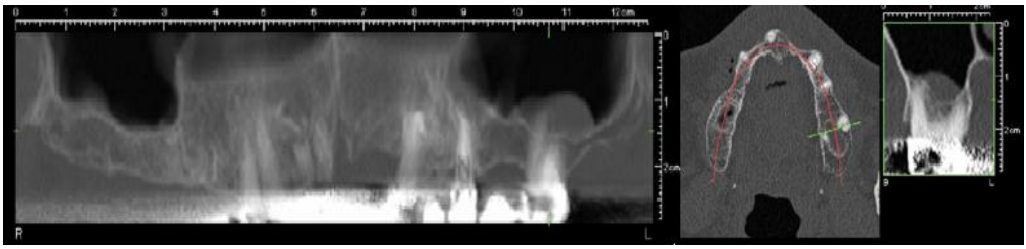

Fig. 6. Odontogenic cyst in relationship with the first left molar

Calibration and reliability

The CT scans were reviewed independently by 2 oral surgeons and 2 maxillofacial surgeons trained by a radiologist with experience of over 1,000 scans at the time of the study. The diagnostic criteria were developed on the basis of the published literature, and in the case of a disagreement, a consensus was reached after a discussion between the observers. Each examiner measured and assessed all the CT images twice.

Statistical analysis

Obtained patient data and scan data were recorded in a *SPSS* database (IBM). Statistical analysis was performed using *SPSS version 20.0* for Windows 7 (IBM). Logistic regression analysis was performed to determine the effects of gender and age on the abnormalities. The level of significance was set at 5%. The chi-square test was used to compare groups. An error probability of <0.05 was accepted as significant.

RESULTS

Mucosal thickening was the most frequently observed abnormality (68.3% of the sinuses). It is generally associated with some kind of irritation, such as odontogenic pathology or allergic phenomena.

Either one or both sinuses of 9 patients showed total opacification, which would suggest an occurrence of sinusitis. However, sometimes opacification can also be found in abnormalities other than sinusitis, such as mechanical trauma, barotraumas and hemorrhage (9). In addition, a final diagnosis of sinusitis may also be considered when clinical signs and symptoms are present and such factors were not evaluated in this study.

Mucous retention cysts were the second most frequently found inflammatory abnormality (15.8% of the sinuses). This result is similar to other studies (9).

4 of these patients showed polypoidal mucosa.

One patient showed an odontogenic cyst in relationship with the first left molar that evolved towards the maxillary sinus, one patient had a tooth in the sinus and another patient had an osteoma (fig.7). These cases were not considered statistically significant.

In most people the maxillary sinus develops as a single space with various compartments. Usually the septa are incomplete,

but in rare cases, complete septa can divide the maxillary cavity. 21.7% of the patients had unilateral maxillary septum and 8.3% had bilateral maxillary sinus septum.

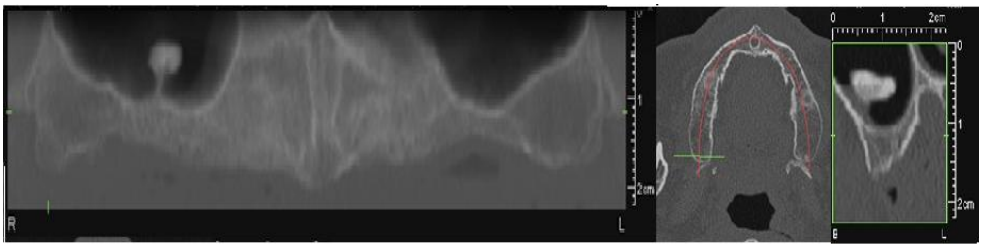

Fig.7. Osteoma in the right maxillary sinus

Pathologic findings in either one or both sinuses were found in 89 patients (74.2%). 49 patients (40.83%) showed pathologic signs in both and 40 patients (59.16%) in either one of their sinus. 31 (25.8%) of the 120 investigated patient scans showed no pathologic signs within either left or right maxillary sinus (tab I).

TABLE I
Findings tabulated for both sinuses, unilateral and bilateral

Findings	Unilateral	Bilateral
Normal	57	31
Mucosal thickening	24	29
Septum	26	10
Pseudocyst	13	3
Complete opacification	7	2
Polyp	2	2
Odontogenic cyst	1	0
Tooth in sinus	1	0
Osteoma	1	0

Out of 67 male patients 44 (65.67%) had at least some pathology in either of the sinuses, whereas only 30 of the 53 investigated scans of female patients (56.6%) showed pathologic signs in either sinus.

Fisher's Exact Test (p=0.029) showed a statistical correlation between gender and pathology. Males tend to present pathology more often (66.2%) than females (54.7%). The logistic regression results showed an association between gender (p=0.028) and pathology. In terms of odds ratio, the odds of having pathology as a male is higher by 62.4%. There was no correlation between age and pathology (p=0.847)

The logistic regression results showed no association between age (p=0.068) and gender (p=0.773) with the maxillary sinus septa for the study group.

DISCUSSION

Several studies have reported a great variability in the prevalence of incidental findings in the maxillary sinuses of asymptomatic subjects when multiplanar images are used. CT scanning studies found abnormalities in approximately 30% of cases (5, 6) and CBCT studies reported a prevalence ranging from 24.6% to 56.3%. Also, gender and age were significantly associated with pseudocysts (p=0.027) and mucosal thickening (p<0.001), respectively (4, 7, 8). In our study, we detected incidental abnormalities in 74.2 % of the cases and no association between age, gender and sinus conditions. Variations in image interpretation and diagnostic criteria and influence of the climate among differences geographical areas can influence abnormality rates (4, 5, 6, 10, 11, 12).

Differences in prevalence found in this study compared with the known literature could be explained by several factors. First, different age and patient groups were in-

vestigated in the various studies. One study investigated 30 patients with paranasal problems determining a prevalence of up to 63% (13), and another study reported on 202 patients having different indications for CT scanning with a prevalence of 82.2% for mucosal abnormalities (14).

Moreover, the definitions for pathologic changes and the applied classification systems vary among the studies. Another factor could be the visualization quality of the different imaging modalities.

Other studies that evaluated the patients about to undergo sinus augmentation observed that 98% were diagnosed with chronic periodontitis, 51% were smokers, and 27% reported a history of symptoms indicative of sinus disease. Eighteen subjects were diagnosed with sinus disease and/or abnormalities (chronic sinusitis, sinus cysts, nasal septum deviation, and ostium stenosis). No significant differences in age, gender, or smoking status between patients with and without sinus conditions were found (15).

The sinus lift technique may be difficult to perform if an aberrant sinus anatomy is encountered during surgical exposure. Previous studies that evaluated the sinus septa found a prevalence of one or more septa per sinus to be 26.5%. Another research team from France found that forty-six subjects (61%) had no bony septa or had septa less than 4 mm (16, 17). A study made on edentulous subjects found a prevalence of maxillary sinus septa of 21.58% and no association between age and gender with the maxillary sinus septa (18).

The present study is limited by several factors. The two observers in this study were not trained radiologists but they were clinically experienced oral and maxillofacial surgeons using CT in clinical routine. Blood and pus appear radiological identical and cannot be discriminated.

Inflammation in the paranasal sinus is a frequent disease and can result from a variety of causes such as infection, chemical irritation, allergy, introduction of a foreign body, or facial trauma. Periodontal disease or rarefying or sclerosing osteitis may cause a localized mucositis in the adjacent floor of the maxillary antrum. Malignancies, also, have to be identified. Incidental findings were the main focus of our study and it provides information on the frequency of anatomic and pathologic findings in the maxillary sinus in CT images of edentulous patients.

CONCLUSIONS

The vast majority of the patients had at least one pathological finding. CT is the most appropriate exam to evaluate the maxillary sinus disease and anatomical variations, before sinus floor elevation.

CLINICAL EPIDEMIOLOGICAL STUDY ON THE INCIDENCE OF *ESCHERICHIA COLI* INFECTIONS IN THE CANCER PATIENTS ADMITTED TO SURGERY DEPARTMENT II OF THE IASI REGIONAL ONCOLOGY INSTITUTE IN 2013 (Abstract). **The aim** of study was to identify pathogens involved in hospital-acquired or community-acquired infections in patients suffering from various types of cancers. **Material and methods**. A clinical epidemiological study included a group of 355 cancer patients admitted and operated at the Surgery Department II of the Iasi Regional Oncology Institute in 2013 was performed using data from hospital statistical service and the surgery and laboratory records, then processed by epidemiological and statistical methods. **Results**. In cancer patients the pathogen most commonly involved in infections was *E. coli*, followed by *Klebsiella pneumoniae*, *Pseudomonas aeruginosa*, *Staphylococcus aureus*, and *Enterococcus faecalis*, *Enterobacter cloacae* and *Acinetobacter*. Analysis of bacterial resistance to antibiotics of the pathogen most commonly involved revealed that of the 29 *E. coli* strains 22 were tested for resistance/sensitivity to ampicillin; of these, 19 strains showed resistance, and only 3 were sensitive; 14 *E. coli* strains of were resistant to cephalosporins and 8 sensitive; all strains tested were sensitive to carbapenems, imipenem or meropenem and polypeptides (colistin); the 10 tested strains showed resistance to monobactams (aztreonam). **Conclusions**. *E. coli* was incriminated in most urinary tract infections, the other pathogens being identified sporadically. Surgical wound infections were caused mostly by *E. coli* and *Staphylococcus aureus*, followed by *Pseudomonas aeruginosa*. In our study we encountered increased resistance of *E. coli* to penicillins, cephalosporins, monobactams (aztreonam), fluoro-quinolones and tetracyclines. **Keywords**: HOSPITAL-ACQUIRED INFECTION, CANCER, SURGERY, ESCHERICHIA COLI.

The incidence of infections associated to diseases requiring hospital care varies highly in relation to many factors of which the peculiarities of the underlying disease and

the presence of co morbidities rank first. Not always the medical act itself creates risks for infection. A number of causes or mechanisms may be involved, accounting for the pronounced epidemiological and clinical polymorphism of hospital-acquired infections, and implicitly for the major difficulties in their prevention and treatment.

Many pathogens can cause infections in hospitalized patients, often highly susceptible due to immunosuppression, as often is the case of cancer patients.

The origin of infection can be both endogenous, self-infection, the organisms responsible originating from the patient itself, and exogenous, through various ways and routes of transmission. Hospitalized patients, cancer patients included, are at high risk of infection which can be acquired both during hospital stay, when it occurs some time after admission or after a short or longer period of time after discharge, depending on the incubation period. The pathogens capable of causing infections in cancer patients are most often bacteria resistant and multi-resistant to antibiotics.

Colonization of patients during medical-surgical procedures occurs due to unhygienic lifestyle and as a result of long-term multiple investigations or treatments.

MATERIAL AND METHODS

This clinical epidemiological study included a group of 355 cancer patients admitted and operated at the Surgery Department II of the Iasi Regional Oncology Institute in 2013, of which 53 (14.92%) were detected to have hospital-acquired (43: 12.11%) and community-acquired infections (10: 2.8%). Data were obtained through cooperation with the hospital statistical service, and the study of the surgery and laboratory records. The results were processed and interpreted by epidemiological and statistical methods.

RESULTS AND DISCUSSION

In the 53 cancer patients with infections, the laboratory investigations done on various pathological samples identified 18 bacterial species involved in infectious episodes (tab. I, fig. 1).

In the 53 patients with infection, 93 identifications were obtained because some patients had multiple co-infections and some infections were caused by several pathogens.

In cancer patients the pathogen most commonly involved in infections was *E. coli*, followed by *Klebsiella pneumoniae*, *Pseudomonas aeruginosa*, *Staphylococcus aureus*, and *Enterococcus faecalis*, *Enterobacter cloacae* and *Acinetobacter*.

The underlying disease of the patients who contracted hospital-acquired infections with *E. coli* varied widely, the most common being cancers of the rectum (4 cases), lung (3), colon (2), and ovary, uterus, skin, sarcoma, liver, stomach one each.

Surgical wound infections were most often caused by *E. coli* and *Staphylococcus aureus*, 9 identifications each, followed, in order, by *Pseudomonas aeruginosa* (7 identifications), *Klebsiella pneumoniae* (6), *Acinetobacter* (4), *Enterococcus faecalis* (4), *Enterobacter cloacae* (3).

E. coli was incriminated in most urinary tract infections (14 % patients of the 22 patients from whom urine samples were collected had urinary infection with *E. coli*), the other pathogens being identified sporadically.

E. coli, pathogen with an increasing frequency, was found in 9 of the 49 examined wound secretions, equaling *S. aureus*. Of the nine wound samples, 7 were superficial and 2 deep.

TABLE I

Bacterial species involved in the infections detected in cancer patients

No.	Bacterial species	No. of infections	% infections
1.	*Escherichia coli*	29	31.86
2.	*Klebsiella pneumoniae*	16	17.58
3.	*Pseudomonas aeruginosa*	10	10.98

Providencia stuartii	1s	1									
Enterococcus faecium	1s	1	1								
Streptococcus pyogenes											1
Citrobacter freundii	1p	1									

s=superficial; p=deep

E. coli caused a total of 29 hospital-acquired infections, being also isolated from blood cultures, bile culture, peritoneal fluid, and catheter.

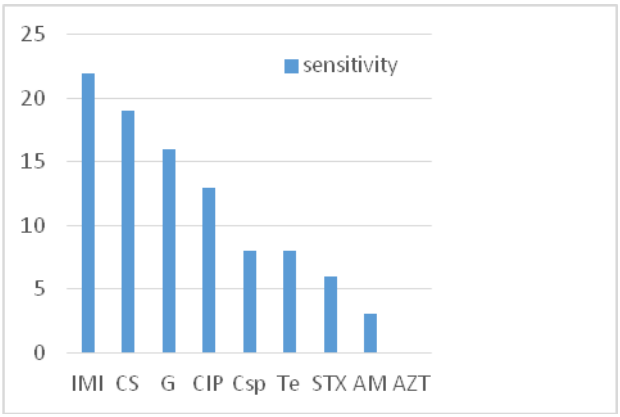
Analysis of bacterial resistance to antibiotics of the pathogen most commonly involved in infections in our cancer patients revealed the following (tab. III): of the 29 *E. coli* strains 22 were tested for resistance/sensitivity to ampicillin; of these, 19 strains showed resistance, and only 3 were sensitive; 14 *E. coli* strains of were resistant to cephalosporins and 8 sensitive; all strains tested were sensitive to carbapenems, imipenem or meropenem and polypeptides (colistin) (22 to carbapenems and 19 to colistin, respectively); the 10 tested strains showed resistance to monobactams (aztreonam).

The 2012 antibiotic use report of the Institute of Public Health, based on data obtained by IMS Health and published on its website, *E. coli* resistance to cephalosporins (in agreement with the result of our study), fluoroquinolones and aminoglycosides is mentioned. In our study, the strains circulating in the Iasi Regional Cancer Institute showed sensitivity to aminoglycosides.

TABLE III

Analysis of bacterial sensitivity to antibiotics

Antibiotic	Tested strains of *E. coli*	Sensitive strains *E. coli*	
		No.	%
Ampicillin	22	3	
Cephalosporins	22	8	
Carbapenems – imipenem, meropenem	22	22	
Monobactams - Aztreonam	10	0	
Gentamicin	22	16	
Tetracycline/doxycycline	21	8	
Ciprofloxacin	21	13	
Colistin	19	19	
Sulfamethoxazole	9	6	



Legend
Ampicillin - AM
Cephalosporins -Csp
Imipenem - IMI
Aztreonam -AZT
Gentamicin - G
Tetracycline/doxycycline - Te
Ciprofloxacin - CIP
Colistin - CS
Sulfamethoxazole – STX

Fig. 2. Sensitivity to antibiotics of *E. coli* strains isolated from cancer patients with infections

CONCLUSIONS

Our research showed that the pathogen most commonly involved in nosocomial infections in the studied cancer patients was *E. coli*, followed by *Klebsiella pneumoniae*, *Pseudomonas aeruginosa*, *Staphylococcus aureus*, *Enterococcus faecalis*, *Enterobacter cloacae*, and *Acinetobacter*.

E. coli was incriminated in most urinary tract infections, the other pathogens being identified sporadically. Surgical wound infections were caused mostly by *E. coli* and *Staphylococcus aureus*, followed by *Pseudomonas aeruginosa*. In our study, we encountered increased resistance of *E. coli* to penicillins, cephalosporins, monobactams (aztreonam), fluoro-quinolones and tetracyclines. The tested *E. coli strains* were 100% susceptible to carbapenems and polypeptides. Of the 22 *E. coli* strains tested for resistance/ sensitivity to aminoglycosides, 16 were sensitive to gentamicin, and 6 exhibited resistances to it, but showed sensitivity to amikacin.

PERSONALITY PROFILES AND RISK DIET BEHAVIORS – A CASE-CONTROL STUDY ON TEENAGERS FROM TIMIS COUNTY, ROMANIA (Abstract): In the study we conducted we aimed at investigating the relation between personality profiles and risk diet behaviors in teenagers. This study was a case-control one and we applied 2 questionnaires (Freiburg Personality Inventory – FPI with 212 items) and CORT 2004 (items Q94-Q116 of diet behavior) on a sample of 2908 teenagers (51.5% girls and 48.5% boys). Cronbach`s alpha index was 0.802 for FPI and 0.730 for items Q101-Q109 of CORT. Personality profiles were built by an Excel 2003 Program. Statistical analysis was realized with SPSS 16 program applying Chi square ($\chi^2$) and gamma ($\gamma$) correlation. Personality features of teenagers` with high and without risk diet behavior were analyzed. Results obtained: personality profiles and statistical results indicated the existence of a significant statistical difference of aggressiveness and domination between teenagers with high and no consumption of butter and/or lard (Q103) (χ^2=6.872, Sig. 0.032 and χ^2=6.922, Sig. 0.031 respectively), of juices from the market (Q106) (χ^2=9.055, Sig. 0.011 and χ^2=14.571, Sig. 0.001 respectively). Aggressiveness correlated with consumption of fried potatoes (Q109) (χ^2=6.144, Sig. 0.046) too. Correlation γ indicated direct proportional relations of aggressiveness with: Q103 (γ=0.215, Sig. 0.017), Q106 (γ=0.224, Sig. 0.004), Q109 (γ=0.242, Sig. 0.012); and of domination with: Q103 (γ=0.234, Sig. 0.008), Q106 (γ=0.073, Sig. 0.000). In conclusion, there is a direct proportional relation between consumption of: butter/lard, juices from the market and teenagers` aggressiveness, domination; and a similar relation between consumption of fried potatoes and aggressiveness. **Key words:** PERSONALITY PROFILES, TEENAGERS, RISK DIET BEHAVIORS

Risk diet behaviors met in teenagers represent the rule rather than exception (1). Prevention strategies consist in healthy nutritive behavior promotion in schools; like fresh fruits or bread and milk consumption (2). On the other hand personality profiles established for the teens` age group present specific personality features, like high nervousness, high aggressiveness, high excitability and high domination (1).

In our study we aimed at investigating the relationship between teenagers` personality profiles and their diet behaviors with high risk and no risk, in the Timis County, Romania.

MATERIAL AND METHOD

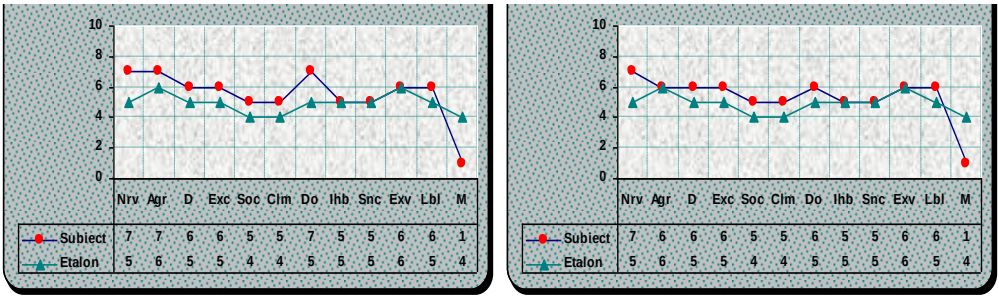
The study was performed on a statistically representative (2908 teenagers, with ages between 15 and 19 years) and homogenous (51.5% girls and 48.5 % boys) sample, provided by secondary schools from the urban area of the Timis county (Timisoara, Lugoj and Deta). The sample was stratified in nests, the sample unit being the class group. This study was a case-control one and it consisted of applying 2 questionnaires: Freiburg Personality Inventory (3) (212 items with Cronbach`s alpha index = 0.802) normalized for Romanian population and CORT 2004 questionnaire (1) (23 items of diet behavior with Cronbach`s alpha index 0.551; Q101-109 with Cronbach`s alpha index = 0.730). The 2 questionnaires were administered individually and anonymously. Work time was 60 minutes. The answering proportion was 74.6%. Depending on risk level we found 5 groups of teenagers, and chose for study the groups with risk 0 (control) and 4 (case with highest level of risk).

We established and compared the personality profiles of the 2 groups of teenagers for certain foods found with high risk: butter/lard (Q103), juices from the market (Q106) and fried potatoes consumption (Q109). Personality profiles consisted in

Nervousness (Nrv), Aggressiveness (Agr), Depression (D), Excitability (Exc), Sociability (Soc), Calm (Clm), Domination (Do), Inhibition (Inh), Sincerity (Snc), Extraversion (Exv), Emotional lability (Lbl). They were built by an Excel 2003 Program and considered the median frequency value of all the 9 ranks of each personality dimension intensity. Statistical work was performed with SPSS 16 Program. In order to avoid small number of cases (under five) we reduced the 9 intensity ranks of the personality profiles to 3 (1 = 1-3 - low intensity; 2 = 4-6 - the average and 3 = 7-9 - high intensity of the feature).

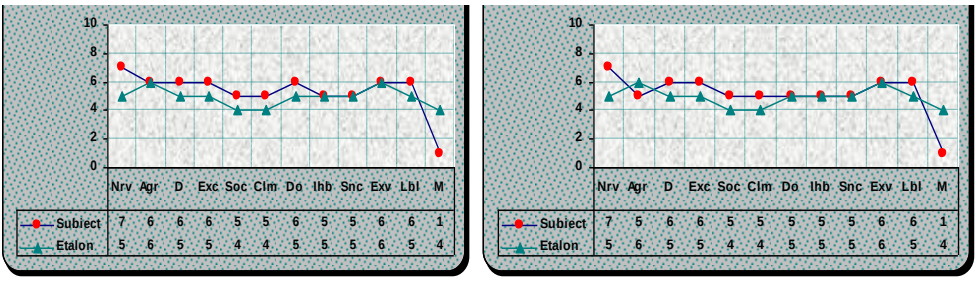
RESULTS

When we analyzed comparatively the personality profiles of the teenagers with high and no risk diet behaviors we obtained the following profiles for: **Q103** (consumption of butter and/or lard, Q103-4 high risk behavior and Q103-0 no risk behavior) (fig.1); **Q106** (consumption of juices from the market, Q106-4 high risk behavior and Q106-0 no risk behavior) (fig.2); **Q109** (consumption of fried potatoes, Q109-4 high risk behavior and Q109-0 no risk behavior) (fig. 3).



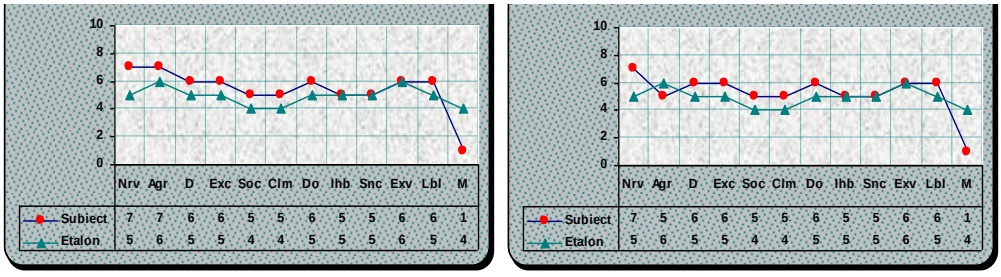
Q103-4 **Q103-0**

Fig. 1. The personality profiles of teenagers with high and no consumption of butter and / or lard



Q106-4 **Q106-0**

Fig. 2. The personality profiles of teenagers with high and no consumption of juices from the market



Q109-4 **Q109-0**

Fig. 3. The personality profiles of teenagers with high and no consumption of fried potatoes

Applying chi square test (χ^2) we found a significant statistical difference between the two personality profiles referring to aggressiveness and domination as personality features in teenagers with high and no consumption of butter and/or lard (Q103) (χ^2=6.872, Sig. 0.032 and χ^2=6.922, Sig. 0.031 respectively) and high and no consumption of juices from the market (Q106) (χ^2=9.055, Sig. 0.011 and χ^2=14.571, Sig. 0.001 respectively) (tab. I). Aggressiveness was different for personality profiles of teenagers which consumed or not fried potatoes (Q109) (χ^2=6.144, Sig. 0.046) (tab. I). Correlation gamma (γ) indicated direct proportional relations: aggressiveness – Q103 (γ=0.215, Sig. 0.017), aggressiveness – Q106 (γ=0.224, Sig. 0.004), aggressiveness – Q109 (γ=0.242, Sig. 0.012), domination – Q103 (γ=0.234, Sig. 0.008, domination – Q106 (γ=0.073, Sig. 0.000).

DISCUSSION

Previous researches identified the utility of personality questionnaires on the adolescents` personality in correlation with their dietary behavior (2). Freiburg Personality Inventory is an efficient tool in building individual personality profiles valuable in clinical diagnosis and in characterizing healthy individuals (3, 4). In our research studies we discovered the possibility to use FPI in building personality profiles specific to an age group (e.g. teenage) (1). Risk diet behaviors in teenagers are well known and frequently investigated in many studies.

TABLE I

Comparative analytical data (A), χ^2 test (B) and γ correlation (C) for Q103, Q106 and Q109 in relation with Aggressiveness, Domination and their statistical significance

[a]Not assuming the null hypothesis [b] Using the asymptotic std. error assuming the null hypothesis.

Special programs were created in order to change a risk diet behavior into a healthy one (5, 6).

In our study we analyzed together behaviors determined by personality features and diet behaviors.

Teenagers with high risk diet behaviors (7) presented different personality profiles in comparison to teens without these behaviors. When we analyzed the statistical difference (chi square) and gamma correlation we found significant values. Certain diet behaviors (consumption of butter or lard – Q103, consumption of juices from the market – Q106 and consumption of fried potatoes Q109) proved to be connected with teenager aggressiveness and/or domination.

A limit of our study was work with ordinal variables which diminished the possibilities of statistical analysis and of prediction of diet behaviors.

CONCLUSIONS

There is a direct proportional relation between consumption of: butter/lard, juices from the market and teenagers' aggressiveness, domination; and a similar relation between consumption of fried potatoes and aggressiveness.

SYNTHESIS, CHARACTERIZATION AND ANTIOXIDANT ACTIVITY OF SOME NEW THIAZOLIDIN-4-ONE DERIVATIVES (Abstract): **Aim:** To design new thiazolidin-4-ones derivatives and to evaluate their potential antioxidant effects using *in vitro* methods. **Material and methods:** New ethyl esters of the 2-(R-phenyl)-4-oxo-thiazolidin-3-yl propionic acid were synthesized using "one step reaction" between different aromatic aldehydes, thioglycolic acid and beta-alanine ethyl ester hydrochloride. The antioxidant potential of the synthesized compounds was evaluated using the DPPH radical scavenging assay and phosphomolybdenum method. **Results:** Eight thiazolidine-4-one derivatives were obtained in good yields and high purity. The structure of the synthesized compounds was confirmed using IR spectroscopy. The evaluation of antioxidant activity showed that 2-[(4-NO_2)-phenyl]-4-oxo-thiazolidin-3-yl propionic acid ethyl ester (compound 16) was the most active compound. For this derivative the DPPH radical scavenger activity (I% = 91.63%±0.77) and the total antioxidant capacity (absorbance = 1.0691±0.0763) were similar with that of ascorbic acid used as standard antioxidant. **Conclusions:** The antioxidant activity of the thiazolidine-4-one derivatives depends on the nature of the phenyl ring substituents, the NO_2 and OH radicals having the most significant influence. **Keywords:** SYNTHESIS, THIAZOLIDIN-4-ONE, ANTIOXIDANT ACTIVITY.

The concern to design thiazolidine derivatives started in 1928 when penicillin was discovered, and since then the development of new derivatives kept increasing. So far, the thiazolidin-4-ones derivatives had been found to posses various biological actions: anti-HIV1 (1, 2), antibacterial (3, 4), antitubercular (5), antioxidant (6, 7), anti-inflammatory (3, 8) and antitumoral (7, 9, 10).

On the other hand, it is known that oxidative stress is involved in the occurrence and development of many diseases, there are more than 200 diseases caused by oxidative stress and 39 deadly diseases for which there is evidence validating their positive link with oxidative stress. Antioxidants inhibit the oxidative damage induced by radicals and reactive oxygen species (ROS) (11). Thus, the therapy with antioxidants has gained ground in the last years.

Furthermore, commercial availability of

a drug is depending on the cost of production line. A simple and efficient method, a small number of synthetic steps or selectivity in a reaction of many components is desirable for obtaining the drug.

The aim of this study was the synthesis of new thiazolidin-4-one derivatives using an one- step reaction ("domino" reaction) and evaluation of their potential antioxidant effects.

MATERIAL AND METHODS

Reagents. Aromatic aldehyde (4-bromo/4-fluoro/4-chloro/2-methoxy/4-methoxy/4-nitro/2-hydroxi/4-hydroxi-benzaldehyde), thioglycolic acid, beta-alanine ethyl ester hydrochloride, *N,N*-diisopropyl-ethylamine (DIEA), and standard reagents for antioxidant assays were purchased from Sigma Aldrich or Flucka. The toluene was freshly distilled and other solvents were used without further purification. TLC silica gel 60 F_{254} from Merck was used to monitor the reactions.

Methods

Chemistry. The aromatic aldehydes (**1-8**), beta-alanine ethyl ester hydrochloride (**9**) and thioglycolic acid (**10**) were mixed in the presence of *N,N*-diisopropyl-ethylamine (DIEA) used as catalyst. The reaction was carried out by adapting similar methods used for synthesis of other thiazolidine derivatives (12).

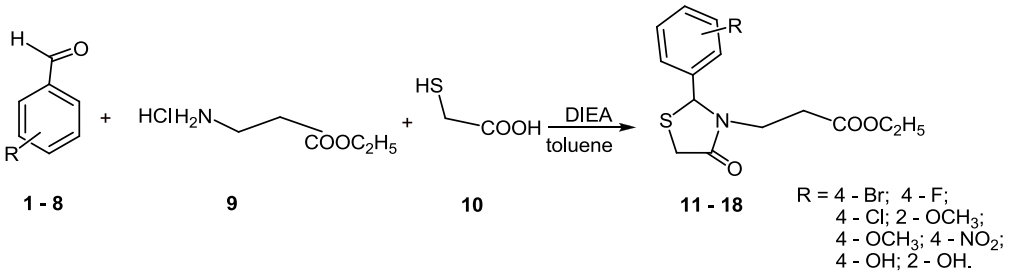

Fig. 1. The synthesis of new ethyl esters of the 2-(R-phenyl)-4-oxo-thiazolidin-3-yl propionic acid

General procedure for synthesis of thiazolidin-4-one derivatives. To beta-alanine ethyl ester hydrochloride (0.01 mol) in 10 ml toluene the aromatic aldehyde (0.015 mol) was added. The mixture was stirred for 5 min and then mercaptoacetic acid 98% (0.02 mol, 1.25 mL) was added. The mixture was stirred again for 5 min and after that *N,N*-diisopropyl-ethylamine (DIEA) (0.013 mol, 2.26 mL) was added and then the mixture was heated to 110-115°C under reflux for 24-30 h under argon. The water was removed by colleting it in a Dien Stark apparatus. The reaction was monitored by TLC using as eluent ethyl-acetate/petroleum ether = 4:6.

The reaction mixture was neutralized with saturated solution of sodium bicarbonate and the organic phase was extracted using ethyl acetate (2 x 25 mL). The organic layer was successively washed with 1M HCl solution and saturated sodium chloride solution, dried over anhydrous $MgSO_4$ and finally filtrated. The filtrate was evaporated and the residue was passed through a silica gel column.

Physico-chemical characterization

Fourier transform infrared (FTIR) spec-

tra were recorded on a Nicolet iS50 FT-IR Spectrometer. All spectra were recorded in the 4000-600 cm^{-1} range at resolution of 4 cm^{-1} over 16 scans. Spectroscopy data were processed with an Omnic Spectra Software. The value of logP (logarithm of partition coefficient between n-octanol and water) as a measure of compound hydrophilicity was calculated using Osiris Property Explorer software (clogP)

Antioxidant assays

The total antioxidant capacity of the tested compounds was evaluated using the phosphomolybdenum method according to the standard procedure of Pietro *et al.* (1999) with some modifications. Briefly, the sample solution (300 µL, 5 mg/mL in methanol) was mixed with 3 mL reagent solution (0.6 M sulphuric acid, 28 mM sodium phosphate and 4 mM amonium molybdate). The samples were incubated at 95°C for 90 min. After the mixture has cooled to room temperature, the absorbance of samples was measured at 695 nm against a blank (300 µL methanol mixed with 3 mL reagent solution) using the GBC-Cintra 2020 UV-VIS Spectrophotometer. Ascorbic acid was used as standard antioxidant.

The DPPH radical scavenging activity. DPPH is a stable nitrogen-centered free radical that is scavenged by antioxidants, changing its color from violet to yellow upon reduction by either the process of hydrogen or electron donation. The sample solution (300 µL, 10 mg/mL in methanol) was added to 2.7 mL solution of DPPH in methanol (dilution 1% from a solution of 0.043%).

The mixture was left for 30 min in the dark and then absorbance was measured at 515 nm against a blank using the UV-VIS spectrophotometer. Ascorbic acid was used as standard antioxidant.

The scavenging capacity was calculated according to the following equation:

$I\% = (Abs_{t=0} - Abs_{t=30min}/Abs_{t=0}) \times 100$

where:

$Abs_{t=30min}$ is the absorbance of the tested compound after 30 minutes.

$Abs_{t=0}$ is absorbance of DPPH methanol solution without sample.

Statistical analysis. The antioxidant assays were carried out in triplicate. Data were analyzed by the analysis of variance (ANOVA) ($p < 0.05$) and were expressed as means ± SD.

RESULTS AND DISCUSSION

Chemistry. The physical characteristics of the compounds are presented in Table I. The compounds looked like colorless or yellow liquids, excepted for the compound (17) that was solid. The value of *clogP* calculated using a free software showed a high lipophilicity (value of the *clogP* is more than 2.5) for thiazolidin-4-one compounds substituted on aromatic ring with 4-Br (*clogP* = 2.76), 4-Cl (*clogP* = 2.67) and 4-NO_2 (*clogP* = 2.60).

The chemical structure of the compounds was confirmed using FT-IR spectroscopy (tab. II). In the IR spectra the absorption band of CO from ester group appeared in the range of 1726-1728.87 cm^{-1}. The thiazolidine ring was identified by the bands characteristic of CO group (1673-1676 cm^{-1}) and C-S bond (622-644.5 cm^{-1}). The characteristic bands of aromatic ring appeared in the range of 2979-2981 cm^{-1} and the phenyl ring substituents appeared at: 1155.62 cm^{-1} (C-F), 767.93 (C-Cl), 1520.4 and 1344.87 cm^{-1} (NO_2), 3270.59 (O-H), 3233.78 (O-H). The C-Br bond had a absorption less than 650 cm^{-1}.

Antioxidant assays.

The total antioxidant capacity. The assay for total antioxidant capacity was based on the reduction of Mo^{+6} to Mo^{+5} by the tested

compounds followed by formation of a green phosphate/Mo^{+5} complex at acid pH. The results of the tested compounds are listed in table III. The most active compound was thiazolidin-4-one derivative with NO_2 on the phenyl ring (compound 16), for which the absorbance (1.0691±0.0763) was similar with that of ascorbic acid used as reference (1.00±0.4052). The compound (11) with Br as substituent on aromatic ring also had important activity (0.8467±0.0406), the value of the absorbance being comparable with that of ascorbic acid.

The DPPH radical scavenger activity. The results of the DPPH radical scavenger assay are presented in fig. 2. The most active compound was compound 16 with NO_2 as substituent on aromatic ring for which the inhibition (91.63%±0.77) was very close to that of ascorbic acid (AA) (99.01 ± 0.32). Compounds 17 and 18 with OH radical on aromatic ring also showed important scavenger activity, the inhibition exceeding 60%.

TABLE III

Absorbance of the tested thiazolidin-4-one derivatives (5 mg/ml)

Sample	R	Absorbance	Sample	R	Absorbance
11	4-Br	0.8467±0.0406	15	4-OCH_3	0.4622±0.0221

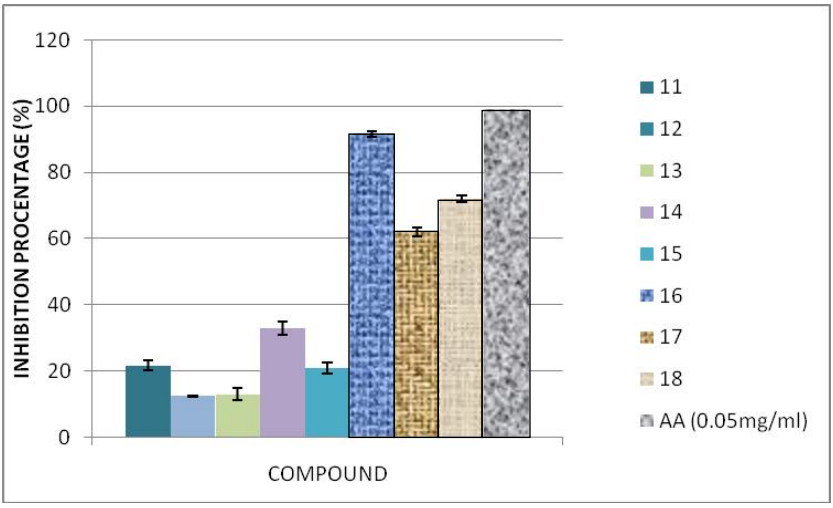

Fig. 2. Antioxidant activity – DPPH scavenger radical

CONCLUSIONS

Some new 1,3-thiazolidin-4-one derivatives have been synthesized. The synthesized compounds have been physically characterized (yield, molecular formula, molecular weight, solubility in different organic solvents, clogP) and their chemical structure was confirmed by FT-IR spectroscopy. The

antioxidant potential of the synthesized compounds has been evaluated using the DPPH radical scavenger assay and phosphomolybdenum method. The results suggest that the most active compound is 2-[(4-NO_2)-phenyl]-4-oxo-thiazolidin-3-yl propionic acid ethyl ester (compound 16) the DPPH radical scavenger activity and total antioxidant capacity of which was comparable to that of ascorbic acid.

CONTRIBUTIONS REGARDING THE LEAF HISTO-ANATOMY OF SOME PELARGONIUM SPECIES

Cristina Elena Iancu, Oana Cioanca, Cornelia Mircea, Monica Hăncianu
University of Medicine and Pharmacy „Grigore T. Popa"-Iaşi
Faculty of Pharmacy
Department of Pharmacognosy

CONTRIBUTIONS REGARDING THE LEAF HISTO-ANATOMY OF SOME PELARGONIUM SPECIES (**Abstract**): *Pelargonium* L. genra (Fam. *Geraniaceae*) includes over 250 species, most of it native to southern Africa. Nowadays, four perennial species are cultivated in Romania as ornamental plants. Our **aim** was to establish the main characteristics and differences that occur between *Pelargonium zonale, P. hispidum, P. grandiflorum, P. peltatum* and *P. radens*. All in all, the quantitative differences (regarding the leaf-stalk, blade and trichomes) have a taxonomical value for all five species included in the research. **Materials and methods:** The plant material was represented by fresh leaves harvested from 5 species of *Pelargonium*: *P. peltatum* (L.) Aiton, *P. radens* H.E. Moore, *P. grandiflorum* (Andrz.) Willd., *P. hispidum*. (anthesis phase) and preserved in ethanol 70%. Using a dissecting microscope, sections were made through leaf blade surface and cross sections of/ for leaf stalk and blade. **Results:** The common characteristics of the leaf is the palmatilobate blade with long petiole. Although many studies regarded glandular trichomes from *Pelargonium* leaves, most of the leaf structures are still unknown. The most important for the quality and quantity of essential oil extracted from *Pelargonium sp.* are trichoms. **Keywords**: *PELARGONIUM SPECIES*, ANATOMY, MEDICINAL PLANTS, DECORATIVE PLANTS.

Pelargonium genre represents a large number of species that were brought to Europe from southern Africa. Species of Pelargonium have long been cultivated due to their attractive scents and bright colors (1).

At the beginning the most common were the species with red flowers. Ever since, their popularity increased slowly along with the horticultural enhancement until 1830. The abundant foliage form and color were especially valued.

Starting with 1870 horticultural improvement of pelargonium reaches the highest peak (a larger variety of colors, flowers, forms and a longer flowering season).

Nowadays, the majority of pelargonium species stand out through vigorous plants, with variated colors (red, scarlet, white, pink, purple etc.), fragrant, simple, double and sometimes very large flowers (2). It is among the top 20 aromatic plants that are particularly rich in essential oils; therefore most of the chemical studies were concentrated on this fraction.

Our study goal was to establish the existent hysto-anatomical differences between five species of *Pelargonium* considering that, such variations will be notable

in the chemical composition of the volatile oil. Therefore, the emphases of this paper especially regarded the structure, place and density of the glandular trichomes.

The present research is part of a larger study, the chemical analysis and biological potential of the essential oil will be included in a following paper.

MATERIAL AND METHODS

1. Plant material. The plant material was represented by fresh leaves harvested from 5 species of *Pelargonium*: *P. peltatum* (L.) Aiton, *P. radens* H.E. Moore, *P. grandiflorum* (Andrz.) Willd., *P. hispidum*. (anthesis phase) and preserved in ethanol 70%. The plants were cultivated in the greenhouse of the Botanical Gardens in Iaşi.

2. Preparation of the microscopic sections. Using a dissecting microscope, sections were made through leaf blade surface and cross sections of/ for leaf stalk and blade. The microscopic preparations were colored with iodine green and ruthenium red and then, analyzed with NOVEX (Holland) photonic microscope. The photographies were taken with Olympus photo camera.

RESULTS AND DISCUSSION

Petiole. Cross sections did not show significant discrepancies between the basis and the top of the leaf blade. It was noted that the number of conducting fascicles was higher at the basis than for the rest of the leaf. Thus, in accordance with other researchers (3,5) we analyzed sections from the middle of the leaves.

The cross section had a circular shape excepting *P. Radens* and *P. grandiflorum* with semicircular-elyptic shape and the plane adaxial surface, whereas the second species has the thickest leaf stalk (4).

Epidermis consisted of isodiametric cells with external and internal wall of cells slightly thicker than the lateral ones; the external wall was couvered by a thin cuticle.

External collenchymatous parenchyma was typically lacunar, hypodermic cell layer was much smaller and tangentially collenchymatised. The number of cell layers in the anatomical area ranges from 4 to 6 and only the external parenchyma of *P. hispidum* is thicker (8-9 layers), many cells containing a single or a few crystals of calcium oxalate.

In the epidermis of the 5 species included in the study glandular and surface trichomes were found; their number, thickness and dimensions variates from one species to another (tab.I, fig.1-5).

Sclerenchyma ring bylayer is thicker (three rows) near the vascular bundle; the polygonal cells present thickend walls that are lignified. *P. hispidum* presented sclerenchyma (2-4 rows), with fibres that have thick and lignified walls and very large cells, whereas the structure of *P. grandiflorum* sclerenchyma was still primary with weak lignified walls.

Lacunar parenchyma was uncolored with bigger cells than those of the external layer, especially in the median part of the petiole. It was noted that the cells from *P.hispidum* sample contained 1-2 oxalate druses similar to external parenchyma (5).

The vascular bundles bear both xylem and phloem vessels next to the sclerenchymatic fibers. For all five species, the vascular fascicles are in great number and various dimensions alternately, the biggest of them representing central isles in the parenchyma. On the external layer phloem consisted of sieve elements, companion cells and few

large parenchyma cells, whereas the xylem (the vessels disorderly dispersed with parenchyma cells) was situated inside the bundle. Internal layer of xylem had a group of small polygonal cells with moderately thickened walls (tab. II).

TABLE I

Structural differences in petiole epidermis

Species	Surface trichomes		Glandular trichomes	
	Number	**Characteristics**	**Number**	**Characteristics**
Pelargonium peltatum	Dense	- uni/bicellular - long	Sparce	-short: -one basal cell -basal podium (2-3 short cells overlapping) -unicellular gland
Pelargonium zonale	Sparce	- long, thin şi thick - multicellular bunt tipped	Dense	-short: basal podium (2-4 cells) -long: basal podium (3-4 sharp point cells) -globular or pear-shaped gland
Pelargonium radens	Very dense	- short - unicellular - long – bicellular; thick	Dense	-short: basal podium (2-4 cells); globular gland
Pelargonium hispidum	Abundant	- uni/bicellular; rarely with 3 cells - variable dimensions	Dense	-short -medium: basal podium (3-4 cells) -large globular gland
Pelargonium grandiflorum	Very dense	- unicellular - variable dimensions -pointed tip	Very dense	- short: basal podium (3-4 cells) - pear-shaped gland

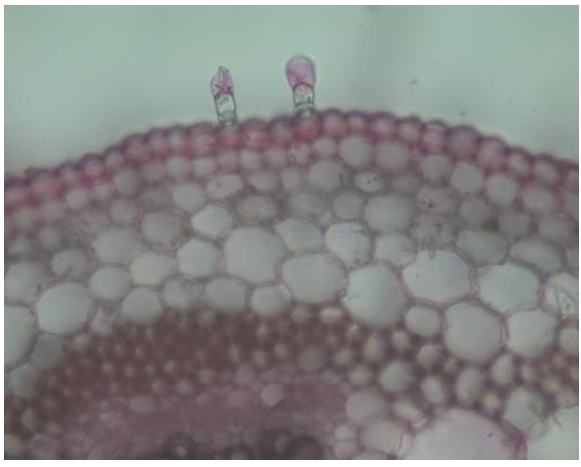

Fig.1. *P. radens* petiol

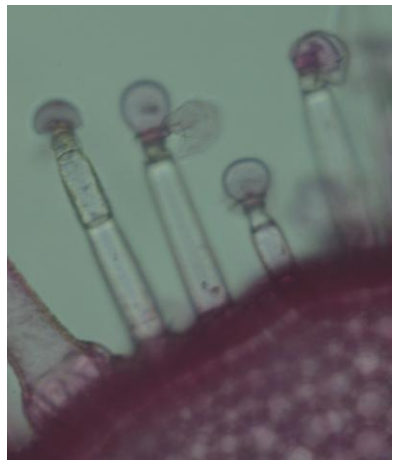

Fig.2. *P. hispidum* petiol

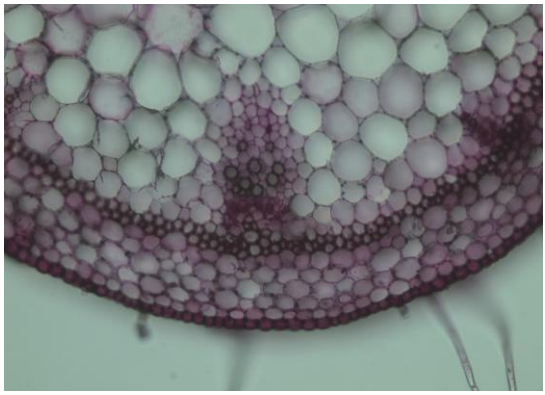

Fig.3. *P. peltatum* petiol

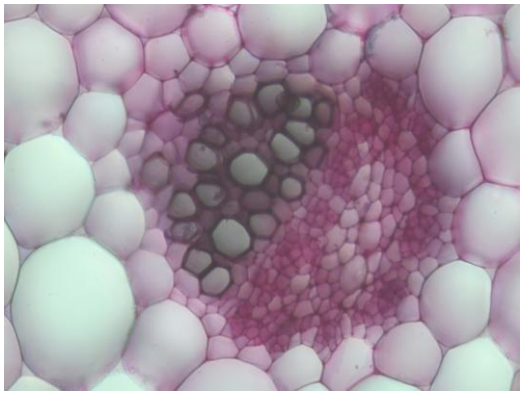

Fig.4. *P. zonale* petiol

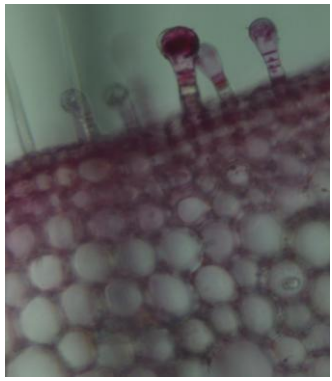

Fig.5. *P. grandiflorum* petiol

TABLE II

Structural differences of vascular bundles for all samples

Species / **Characteristics**	***P. peltatum***	***P. zonale***	***P. radens***	***P. hispidum***	***P. grandiflorum***
Fascicle number	10	11	10	8	19-21
Fascicle type	4 thick 6 thin 1-2 xylem vassels	5 large 6 small 14 at the basis of petiole	4 thick 6 thin	4 large (abundant xylem) 4 small	4 large 4 small 11-13 very small (only phloem)
Central vassel	large, thick	1 large 1 small	1 large	1 large	1 large suround-ed by 2-3 smaller
Sclerenchyma cells	absent	absent	absent	peripheric	peripheric

In *the surface view of the lamina* we noticed the upper epidermis had cells with irregular outline and slightly waved side-walls, whereas the lower epidermis had

very sinuated walls.

In *cross section*, the leaf blade looked like a ribbon and the midveins were thinly (*P. peltatum*) and extremly (*P. grandiflorum)* prominent on the abaxial surface.

All the veins contained one libero-ligneous bundle surrounded by a sheath of polygonal cells, smaller than those from the lacunar tissue.

One of the specific characteristics of *P. grandiflorum* was the presence of 3 opposite fascicles (one large and two small) with xylem elements face to face.

The epidermis has small isodiametric cells with internal and external walls thicker than the lateral ones and the external wall is covered by a very thin cuticle.

The epidermis of all selected species presented stomata and trichomes (surface and glandular) (6) (tab. III).

TABLE III

Stomata and trichomes in *Pelargonium sp*.

Species	**Stomata**	**Surface hairs**	**Glandular trichomes***
Pelargonium peltatum	anomocytic amphistomatic	-uni/bi/pluricellular -uniseriate, variated dimensions -dense and long	- dense and thin - bicellular basal podium
Pelargonium zonale	anomocytic amphistomatic	-uni/bi/pluricellular -uniseriate, variated dimensions -abundant, long and very long	- dense - short: bicellular basal podium - long: tricellular basal podium
Pelargonium hispidum	anomocytic hypostomatic	-uni/bi/pluricellular -uniseriate, variated dimensions -abundant, long and very long	- dense - short: bicellular basal podium -medium: tricellular basal podium - long: tricellular basal podium
Pelargonium radens	anomocytic hypostomatic	-uni/bi/pluricellular -uniseriate, variated dimensions -abundant, long and very long	- dense - short: uni/bicellular basal podium -medium: tricellular basal podium
Pelargonium grandiflorum	anomocytic hypostomatic	-uniseriate, variated dimensions -dense and long -abundant on the abaxial surface and on the midvein	- dense - short: bicellular basal podium -medium: tricellular basal podium - long: tricellular basal podium

*variated dimensions and number on the surface unit, with a basal cell, pluricellular basal podium and one globular-shaped gland

The mesophyll had a unistratified palisade and a bistratified lacunar tissue (7). The main differences that were noted between the five samples of pelargonium consisted in: height of the palisade, number of the layers in the lacunar tissue, abundance and layout of calcium oxalated druses (tab. IV).

TABLE IV

Mesophyll characteristics in *Pelargonium species*

Species	Palisade	Lacunar tissue	Druses
Pelargonium peltatum	-short and wide	-4-5 layers, slightly elongated cells, the size decreases towards the abaxial epidermis	-along the mesophyll
Pelargonium zonale	-short	-5 layers, slightly elongated cells	-only in lacunar tissue
Pelargonium hispidum	-high and long	-3-4 s layers, rounded cells	-sparce only in lacunar tissue
Pelargonium radens	-short	-3-4 layers, small, elongated cells	- only in palisade tissue
Pelargonium grandiflorum	-high	- 4-5 layers, elongated cells	- only in palisade tissue

The following images reveal the most important characteristics of the lamina from the five samples included in the study: *Pelargonium peltatum* (fig. 6-7), *Pelargonium zonale* (fig. 8), *Pelargonium radens* (fig. 9), *Pelargonium hispidum* (fig. 10) and *Pelargonium grandiflorum* (fig. 11).

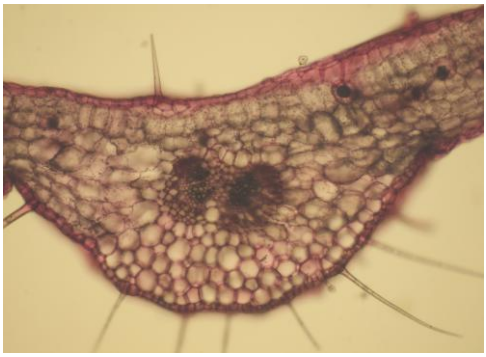

Fig. 6. *P. peltatum* lamina

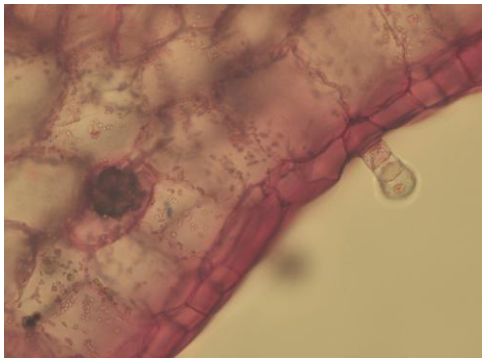

Fig. 7. *P. peltatum* lamina –detail

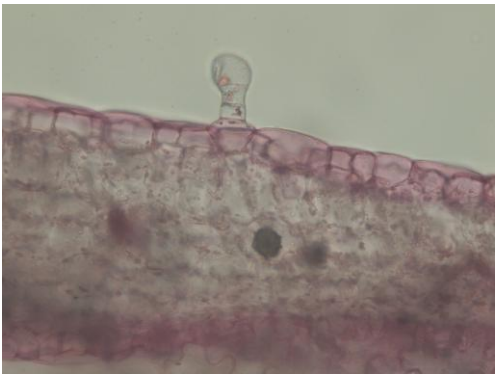

Fig. 8. *P. zonale* lamina

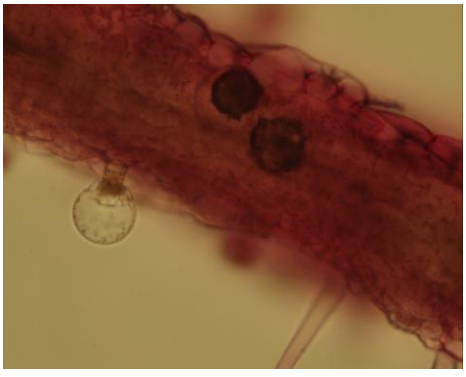

Fig. 9. *P. radens* lamina

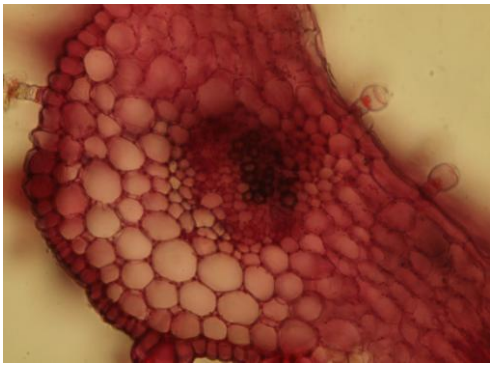

Fig. 10. *P. hispidum* lamina

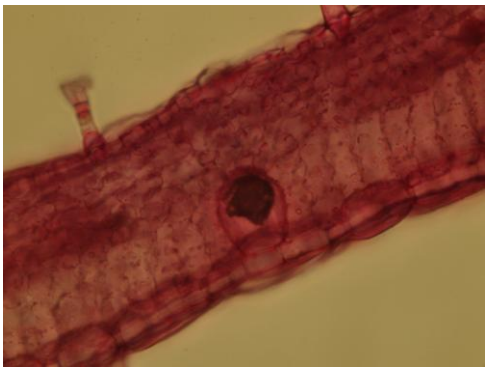

Fig. 11. *P. grandiflorum* lamina

CONCLUSIONS

As we expected, most of the notable differences between the samples were mainly quantitative and have a great taxonomic value. Since the most important for the quality and quantity of essential oil extracted from *Pelargonium sp.* are trichoms, the results showed that *P. peltatum* has a small number of hairs, whereas *P. hispidum* and *P. zonale* have abundant and long hairs. On the other hand, *P. radens, P. hispidum, P. grandiflorum* have the longest trichoms on the petiole. Such differences are to be expected to influence more or less the chemical composition of the plants metabolites. Therefore, our future research is going to establish if there are such correlations.

SULFADIAZINE MODIFIED CS/HA PEC DESTINED TO WOUND DRESSING (Abstract): **Aim:** To present the research results concerning enhanced antimicrobial and release properties of the chitosan derivative with sulfadiazine/hyaluronic acid polyelectrolyte complex (PEC) hydrogel. **Material and methods**: The PECs have been prepared from chitosan of different molecular weight, sulfadiazine chitosan derivative and sodium hyaluronate. The complex structure was assessed by FT-IR spectroscopic method and swelling capacity was followed by weighing measurements. **Results:** It has been establish that chitosan derivative influenced both PEC properties and swelling capacity. **Conclusions:** Incorporation in PEC of the sulfadiazine chitosan is a new way to combine bacteriostatic effect of chitosan with that of sulfadiazine, to control properties, antimicrobial activity in the treatment of the wound.
Keywords: WOUND HEALING, DRESSING, CHITOSAN, HYALURONIC ACID, SULFADIAZINE.

The discovery and development of new antimicrobial drugs is a main goal for scientists because of microbial resistance to a number of antimicrobial agents among a variety of clinically significant species of bacteria (1, 2).

Hydrogels containing grafted chitosan. Both functional groups of chitosan (CS) can be grafted, firstly free amino groups of deacetylated units and then hydroxyl groups of C_3 and C_6 from acetylated and deacetylated units. Grafting is achieved with molecules bearing at least one functional group capable to form covalent bonds with CS as palmitic, lactic or glycolic acids, etc. (3) or aldehydes (4). Multifunctional molecules lead to crosslinking when the concentration of grafts becomes important as in the case of ethylenediaminotetraacetic acid (EDTA) which contains four functional groups (5). Catalysts (sodium borohydride, 1-ethyl-3-(3-dimethyl aminopropyl carbodiimide bromide, cetyl trimethyl ammonium, p-nitrophenyl), initiators (iron or ammonium sulfate, potassium persulfate, ammonium cerium salt) or organic solvents (pyridine, chloroform) employed in these reactions are considered as toxics for drug delivery. Gamma irradiation (^{60}Co) affects also CS. Indirect grafting of CS with p-cresol, hexyloxyphenol or chlorogenic acid can be performed in presence of enzymes as ţyrosinase.

Grafted CS has interesting properties for wound healing when they exhibit bacteriostatic properties, although because of auxiliary substances their biocompatibility should be carefully controlled. Carboxymethyl CS forms an injectable hydrogel for sustain release of morphine and gentamicin which is useful in wound healing and also it increases the antimicrobial activity of CS. Swelling depends on the electrostatic repulsion of the free ammonium groups which leads to the expansion of the chains and the increase of the water uptake by gel, which frequently happens in acidic solutions. Dissolution of the systems containing grafted CS is rare but they show some advantages as improve the solubilization of lipophilic drugs, protect peptidic and proteinic drugs. EDTA grafted onto CS increases its antibacterial activity by complexation with Mg which in normal conditions stabilizes external membrane by Gram negative bacteria. CS can be used to prevent and to treat infection of the wounds and burns not only because of its intrinsic antimicrobial properties but also due to its capacity to deliver antimicrobial agents to wounds and burns being a carrier for retarded release. CS proved to be efficient in hemostasis acceleration favoring rapid wound healing (6, 7).

Antimicrobial activity is higher for CS with high molecular weight and high deacetylation degree and at low pH.*Kulkarniet al.* reported increased 10 times of antibacterial activity of CS by derivatization with thiazolidinone (8). It have been synthesized temperature-responsive hydrogels by grafting with poly(N-isopropylacrylamide) (PNIPAAm) of CS or HA (9). Both hydrogels show higher transition temperatures than that of PNIPAAm and they are good carriers for hydrophilic and lipophylic drugs. Most of hydrogels containing CS are dual or multi stimuli receptive, while PEC containing HA show a pulsatile behavior under electrical field action. CS/HA PECs absorb a high water amount, this increasing with CS content of PEC (10).

Sulfonamides and their derivatives are among the most useful antimicrobial agents because of their low cost, low toxicity and excellent activity against bacterial infections. Most of antibiotics delivered by systemic way are inefficient for wound healing, therefore choosing of an antibacterial topic agent is important to reduce the risk of sepsis and to bring benefits to general treatment.

MATERIALS AND METHODS

Sulfadiazine, also called sulfapyrimidine or 4-amino-N-(pyrimidin-2-yl)-benzen-sulfonamide (fig. 1) is a white or white-yellow powder, sensitive to light with a melting point of 252-256°C, insoluble in water, alcohol, ether, chloroform, soluble in acetone and diluted acidic or alkaline solutions (11).

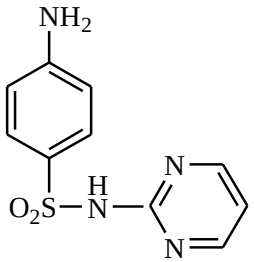

Fig. 1. Sulfadiazine chemical structure

Sulfadiazine is useful in the treatment of meningoccocal, staphyloccocal, streptococcal etc. infections. Based on this action sulfadiazine was selected to modify CS and to obtain formulations with modified and

retarded antimicrobial action.

The procedure of synthesis of the CS derivative with sulfadiazine is described in other paper (12). Chemical structure of the chitosan derivative with sulfadiazine has been confirmed by IR spectroscopy. IR spectrum shows characteristic absorption bands both for sulfonamide unit and also for glucosamine: C=O (amide I) at 1629 cm^{-1}, NH (amide II), 1595 cm^{-1}; phenyl 1546, 839 cm^{-1}, SO_2-N 1259, 1168 cm^{-1}. Degree of substitution of this derivative was 31.64 %. The sulfadiazine CS derivative (SDCS) was used as component in preparation of PEC hydrogels with sodium hyaluronate which was comparatively investigated with PEC containing unmodified CS.

Low (CHL) and medium (CHM) molecular weight chitosan were purchased from Sigma-Aldrich and sodium hyaluronate (NaHA) from *Streptococcus equis* was obtained from Fluka.

Preparation of CS/sodium hyaluronate PEC hydrogels **.**CS/NaHA and SDCS/NaHA PEC hydrogels have been prepared by dissolution of two components in an aqueous solution of formic acid 50% with a polymer concentration of 1 % and then these solutions were mixed in the ratio 1:1 (13). Solutions were continuously magnetically stirred at room temperature ~ 20^oC for 48 hours or 72 hours. The obtained solutions have been filtered and then cast on Petri dishes and dried at oven at 40^oC for 48 hours. It has been obtained thin transparent films in the case of CS/NaHA polyelectrolyte hydrogels and semi-transparent film from SDCS/NaHA polyelectrolyte hydrogels. The films were taken off from Petri dishes and washed with double distilled water for 2 days, recurrently changing the washing water and after that, they were dried at 40^oC for 48 hours.

ATR-FTIR spectroscopy have been recorded at 4 cm^{-1} resolution with 64 scans by means of a spectrometer Bruker VERTEX 70, in absorbance mode, by the ATRFTIR technique with a 45°ZnSe crystal. Penetration thickness was about 100 microns. For each film sample, the evaluations were made on the average spectrum obtained from three recordings. Background and sample spectra were obtained in the 500 to 4000 cm^{-1} wavenumber range. The processing of spectra was achieved using a SPECVIEW program.

Swelling behavior was followed by weighing of the dried PEC hydrogels and swollen ones at predetermined time intervals. Swelling was performed in buffer solution of pH 7.4 and swelling degree (SD) was evaluated using eq. (1) (14):

$$SD\ (\%) = \frac{(m-m_0)}{m_0} \times 100 \qquad (1)$$

where m_0 is mass of dry sample and m is mass at moment "t" of swelling.

RESULTS AND DISCUSSION

ATR-FTIR spectroscopy

CS spectrum shows a wide band at 3320 cm^{-1}, assigned to stretching vibration of OH group while the band centered at 1560 cm^{-1} is assigned to bending vibration of NH group (amide II) (NH_2) (15). The HA spectrum has six main bands (16): 1. a wide band centered at ~ 600 cm^{-1} attributed to rotation vibration, δL of the water molecule; 2. a strong band extended from 950 to 1200 cm^{-1}, corresponding to stretching vibration of COO (-COOH) from acids. Assignment was made on characteristic bands of cellulose with a shoulder at 1160 cm^{-1} for asymmetric vibration of $\nu_{C\text{-}O\text{-}C}$ from glycosidic units; 3. a band around

1400 cm^{-1}, which can assigned both to ν_{COO^-} symmetric vibration from carboxylate group and to $\nu_{C\text{-}O^-}$ asymmetric vibration from the same group, allowing distinction between two parts of bond: C=O and $\nu_{C\text{-}O\text{-}}$; 4. a strong band at 1500 - 1700 cm^{-1} which is an overlapping of the bands of amide I and II and various carbonyl ($\nu_{C=O}$) and carboxyl vibrations; 5. a band at ~ 2,900 cm^{-1}, which is $\nu_{C\text{-}H}$ (C-H stretching); 6. a wide and strong band which extended from 2500 to 3600 cm^{-1}, this being a stretching vibration of $\nu_{N\text{-}H}$ and $\nu_{O\text{-}H}$ groups involved in hydrogen bonding. Shoulder from 3100 cm^{-1} is characteristic to *Fermi* resonance of the νN-H with the band of amide II (17).

In all spectra can be identified the band at 1595 cm^{-1} assigned to NH_2 groups of CS and also very clear and strong bands at 1545 cm^{-1} and 895 cm^{-1} corresponding to N-H from sulfadiazine and two bands centered at 837 and 782 cm^{-1}, assigned to pyrimidinic ring (tab. I, fig. 2).

In ATR-FTIR spectra of PEC hydrogels the bands are wider and are shifted in respect with bands of pure components which is a proof of PEC formation. The shape of the ATR-FTIR spectrum of the SDCS/HA film shows differences comparatively with those described by bands at 1595 cm^{-1} assigned to amine (NH_2) group of CS, at 1545 cm^{-1} a strong band due to amide II (NH) and the band assigned to COO^- (symmetric) from HA at 1402 cm^{-1} is clearly distinct which means that not all of amine groups participate to PEC formation being available to provide antimicrobial activity according to well-known mechanism.

Swelling behavior. The swelling capacity is different from a sample to other, the lowest swelling capacity having PEC hydrogel containing sulfadiazine CS derivative (SDCS). The SDCS sample swells in the first 2-3 min reaching a swelling degree of ~1150%, then equilibrium is reached. PEC containing unmodified CS shows a lower rate of swelling up to 30 min, then a plateau is reached, but the degree of swelling is higher of ~ 2500% and ~3700% for CSL / HA and CSM / HA, respectively, high molecular weight being favorable to swelling (fig. 3).

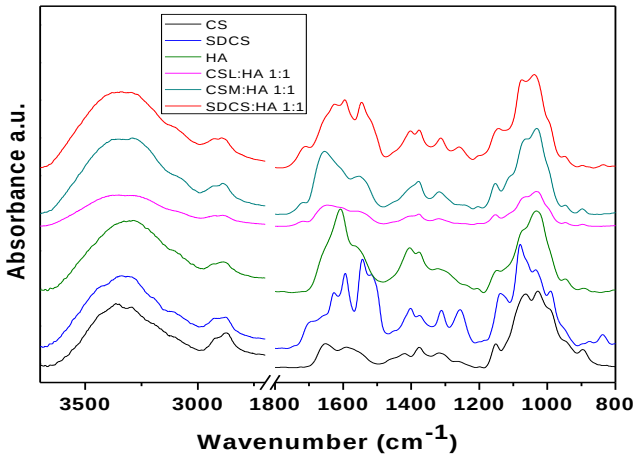

Fig. 2. ATR-FTIR spectra of CS, HA, SDCS and CS/HA PEC

TABLE I
ATR-FTIR bands of the CS/HA and SDCS/HA PEC hydrogels

CSL/HA (cm^{-1})	CSM/HA (cm^{-1})	SDCS/HA (cm^{-1})	Bands assignments
3334	3334	3334	-OH and -NH groups vibrations

		837 (w), 782 (w)	C-H pyrimidine ring

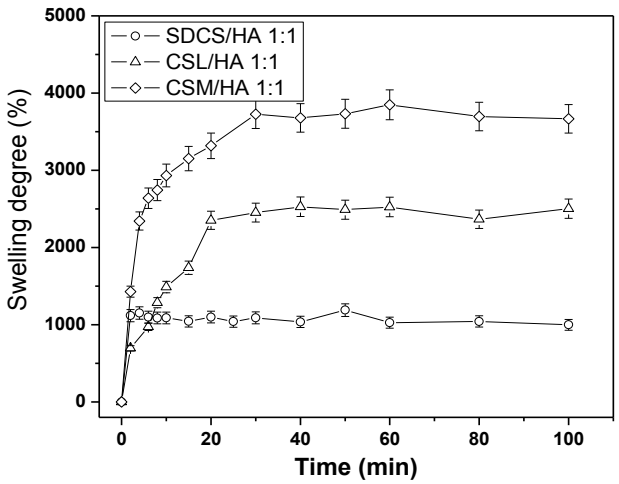

Fig. 3. Swelling profiles of CS/HA polyelectrolyte hydrogels.

CONCLUSION

Grafted chitosan should be considered as a second choice for the preparation of hydrogels, especially for drug delivery systems. Some grafted chitosan hydrogels can be interesting in specific medical or pharmaceutical applications if chitosan is functionalized without auxiliary molecules and if intrinsic properties such as bacteriostatic effect or promotion of wound healing are enhanced by grafting.

Sulfadiazine modified chitosan can be used to prepare polyelectrolyte hydrogels with hyaluronic acid which shows lower swelling capacity which could found potential application in wound healing taking in view their capacity to retain a relatively high quantity of liquid at a low degree of substitution which allow to combine antimicrobial activity of chitosan with that of sulfadiazine.

NEWS

THE MOLECULAR CHANGES IN MALIGNANT PLEURAL MESOTHELIOMA AND THEIR IMPACT ON PROGNOSIS AND TREATMENT

In recent decades, various studies have been conducted to define the molecular characteristics of malignant mesothelioma (MM) cells. Molecular studies have identified somatic genetic and epigenetic alterations in malignant pleural mesothelioma (MPM) cells, associated with altered expression and activation or inactivation of critical genes in oncogenesis. Deregulation of signaling pathways related to differentiation, survival, proliferation, apoptosis, cell cycle control, metabolism, migration, and invasion has been demonstrated in complementary studies. These changes were found by investigating individual gene status in genomic and transcriptomic studies, and were supported by immunohistologic studies. MPM cells show a large spectrum of abnormalities shared with other malignancies, or more specific alterations such as those of the NF2 gene. Comparative studies of series of MPMs have usually demonstrated that both alterations in a given gene and combined genetic and epigenetic alterations are present in MPM subsets, consistent with interindividual variations of molecular alterations. There are therefore at least 2 levels of heterogeneity, at the genome level and at the gene level, suggesting that identification of patient subgroups would be essential to develop more specific therapies. Moreover, the tumor microenvironment, consisting of a large number of different cell types, adds another level of complexity in identifying the best strategy to improve the outcome of this disease. This tumor heterogeneity could explain differences in patient survival and response to treatments. Bernestein L reviews on genomic abnormalities and signal transduction dysregulation have been summarized the molecular changes in MM, focusing on more recent advances in MPM and discussing the level of confidence and limitations of these results, their impact on prognosis and treatment, and the future research required to fill the gaps and enhance the benefit of basic research to improve patients' outcomes. Demonstration of the multiple alterations present in the tumor should encourage research into combined or more global therapies. (Jean D, Daubriac J, Le Pimpec-Barthes F, Galateau-Salle F, Jaurand M-C. Molecular Changes in Mesothelioma With an Impact on Prognosis and Treatment. *Arch Pathol Lab Med* 2012; 136: 277–293)

HEMANGIOMA OF THE PAROTID GLAND: CASE REPORT (Abstract): Hemangiomas account for half of the parotid gland tumors occurring in children. After a rapid increase in the first months of life, some of them gradually regress (until complete disappearance) in a period of several years. Hemangiomas that do not regress over time, grow in size (possibly within a short period of time) or develop complications such as intralesional acute bleeding or thrombosis require aggressive therapy: intralesional corticosteroid injection, sclerotherapy, radiation therapy, laser photocoagulation, embolization, or surgical removal. We present the case of a 12-year-old boy with hemangioma of the left parotid gland diagnosed by CT scan, angio-CT with 3D reconstruction and angiography successfully treated by superselective intraarterial embolization with acrylic glue followed after 4 days by left superficial parotidectomy with facial nerve preservation. **Keywords**: HEMANGIOMA, PAROTID GLAND, SURGICAL TREATMENT.

Salivary gland tumors occurring in children are less than 5% of all tumors, and hemangiomas are the most common (50% *versus* 2% in adults), followed by: pleomorphic adenomas, mucoepidermoid carcinomas, lymphangiomas, acini cells carcinomas (1, 2, 3). The clinical picture of parotid hemangioma is characterized by the presence of a painless swelling, usually confined to the superficial lobe of the gland, but sometimes involving the masseter muscle, bluish discoloration of the overlying skin and a network of vascular capillaries (4). Magnetic resonance imaging is considered to be the first choice in making an accurate diagnosis and investigating the vascular supply of this lesion due to image quality, soft tissue definition, lack of ionizing radiation, additional invasive procedures not being required (5,6). Therapeutically there are two options: a) conservative management and clinical monitoring of parotid hemangioma, given the probability for most of these lesions to resolve spontaneously, and b) a more "aggressive" treatment (systemic corticosteroids or intralesional steroid injection, laser photocoagulation, sclerotherapy,embolization and surgical excision), particularly when parotid hemangiomas are large, deforming, ulcerated or involve neighboring structures, with functional consequences (3, 7, 8, 9, 10, 11).

In this article, we present the case of a 12 years old boy diagnosed at the Department

of Oral and Maxillofacial Surgery with left parotid hemangioma. Management consisted in preoperative embolization and surgical excision of hemangioma by parotidectomy, without postoperative complications, the best morphological, functional and aesthetic results being achieved one year after surgery.

CASE REPORT

A twelve-year-old boy with no associated general diseases was referred to the Department of Oral and Maxillofacial Surgery for the presence of a 5cm x 4cm tumor mass in the left parotid region, poorly defined, soft, compressible, non-pulsatile, painless, and healthy overlying skin; case history revealed that the tumor mass progressively increased in size over the last 10 years (fig. 1). Head and neck CT scan showed a nodular mass located at the superficial lobe of the left parotid gland, 4.4/2.6/4.8 cm in diameter, intensely enhanced (arterial phase) after contrast administration, with a low intensity signal in the middle of the lesion (fig. 2). Angio-CT with 3-D reconstruction showed that the arterial blood supply of the tumor was from the branches of the transverse facial artery and venous drainage into the internal and external jugular vein (fig. 3). Presumptive diagnosis was parotid hemangioma and the therapeutic decision was surgical removal of vascular lesion, due to the lack of natural tumor involution. Angiography (fig. 4) and superselective intraarterial embolization with acrylic glue (Glubran), used in interventional neuroradiology, were performed prior to surgery (fig. 5) in order to reduce tumor vasculature. Four days after arterial embolization, the vascular tumor was removed by superficial parotidectomy, with facial nerve preservation (fig. 6); at 1 year postoperatively the results were very good (fig. 7). Histopathological examination confirmed the mixed type of parotid hemangioma (capillary and cavernous) (fig. 8).

DISCUSSION

Hemangiomas of the salivary glands are benign vascular mesenchymal tumors and may arise from the gland proper or by secondary invasion of subcutaneous blood vessels into the gland structure (12). Congenital

capillary hemangiomas („true" hemangioma according to the classification proposed by Mulliken and Glowacki in 1982) represent 90% of the parotid gland tumors in infants and young children (2). The course is characterized by a rapid growth phase in early childhood (proliferative phase), followed by a gradual spontaneous involution over a period of several years (5). This type of benign vascular tumor is found more frequently in girls, mean age at presentation 4 months, and the overlying skin has a characteristic bluish tint. Comparatively, cavernous hemangiomas (classified as true vascular malformations) occur as a consequence of the abnormal development of blood vessels in late childhood, are not accompanied by a bluish discoloration of the overlying skin, may contain „phleboliths" (a feature that is not found in true hemangiomas), and are unlikely to regress spontaneously, their surgical removal being the treatment of choice (13). There are also compound types (capillary and cavernous), as the case presented in this paper, in which case the final diagnosis is established histologically.

The clinical description of a parotid hemangioma includes: tumor in the parotid area, slowly progressive, poorly defined, soft, compressible, mobile, painless and the overlying skin has sometimes a bluish tint (14). Deformity and severe pain depend on tumor size and the presence of intralesional bleeding or acute thrombosis. History and physical examination are elements supporting the diagnosis of probability, but imaging is needed to confirm the suspicion.

In children, the initially recommended imaging study to salivary gland lesions is ultrasound examination, since the pathology in these locations is generally benign, ultrasound images have good accuracy and no sedation or anesthesia is required for optimal exploration (3). In particular, color Doppler is recommended to explore salivary vascular lesions. Ultrasound protocol of a parotid hemangioma reveals a homogenous mass that replaces most of the parotid gland, with fine echogenic internal septa and numerous intratumoral vessels (described as non-echogenic areas) (5). Color Doppler shows filling of non-echogenic areas, the high vascular density (> 5 per cm^2) differentiating these vascular tumors from others. At CT scan without contrast material parotid hemangioma has the same density as the muscle structure, the administration of contrast material revealing a homogenous, well defined, high absorption mass (1). An accurate diagnosis of juvenile parotid hemangioma sometimes requires an additional fine needle puncture-aspiration (15). T1-weighted magnetic resonance image shows flow voids within the lesion, thus distinguishing parotid hemangioma from other soft tissue lesions encountered in children. On T2-weighted MRI the vascular lesion appears hyperintense to muscle. During hemangioma involution, there are areas of fat replacement that appear hyperintense on T1-weighted images. Magnetic resonance imaging in cavernous hemangioma shows a heterogeneous T2 signal (due to phleboliths and venous lakes) and no intralesional flow voids (1). More recently, as to differentiate between a high and low flow lesion, or hypovascularized and hypervascularized tumor is not always possible, MRI digital subtraction angiography can be used (6). This technique can be safely performed in children of all ages, without complications, providing information on the vascular supply of the explored lesion, information not available by clinical examination or routine magnetic resonance imaging. Our patient was investigated by CT, angio-CT with 3D reconstruction, and angiography,

useful and sufficient data for determining the vascular supply of the parotid lesion being thus obtained.

Therapeutic approach of parotid hemangioma in children should be individualized, initial therapy being less aggressive and the subsequent ones more aggressive. The spectrum of treatment modalities includes: clinical monitoring of tumor involution over several years, corticosteroids (intralesional or systemic), interferon treatment, sclerotherapy, radiation therapy, laser therapy, cryotherapy, arterial ligatures, and surgical excision (3). Since many parotid hemangiomas are likely to regress, the indications for surgery are: increase in tumor size, rapidly growing lesion, non-involuting hemangiona, or intralesional bleeding. It is recommended that tumor vascular supply to be explored by MR angiography or digital subtraction angiography prior to surgical removal of a parotid hemangioma (6). Surgical excision of parotid hemangioma is performed by superficial or total parotid-ectomy, with intraoperative identification and preservation of the facial nerve. The case presented in this article was managed mainly surgically, but we also resorted to a postoperative "artifice" - superselective intraarterial embolization with acrylic glue, a technique used in recent years in interventional neuroradiology to achieve endovascular embolization stability in the treatment of cerebral vascular tumors or malformations (16, 17); the advantage of this therapeutic "mix" was a decrease in the vascular flow to the parotid lesion, facilitating intraoperative hemostasis and, thus, optimal performance of parotidectomy.

CONCLUSIONS

Surgical removal of parotid hemangioma must be preceded by a thorough imaging study of the lesion aimed at clearly detecting the vascular supply (main and collateral) in order to avoid intraoperative bleeding complications.

Superselective intraarterial embolization with acrylic glue just a few days before parotidectomy is a method that decreases vascular flow of a parotid hemangioma, with positive impact on operative performance.

BIOMARKERS AND SILENT CARDIAC DISEASE IN PRIMARY PREVENTION: TIME TO UNMASK THE DAMAGE?

The aim of this study was to examine whether biomarkers can identify silent cardiac target organ damage (cTOD) in a primary prevention population. The researchers observed that one possible way to improve primary prevention of cardiovascular events is to identify those patients who already harbor silent cTOD (i.e., myocardial ischemia, left ventricular hypertrophy, systolic dysfunction, diastolic dysfunction, or left atrial enlargement). This might be possible by screening with a biomarker (e.g. high sensitivity cardiac troponin T [hs-cTnT] or B-type natriuretic peptide [BNP]). The prospective methods used for identifying silent cTOD were transthoracic echocardiography, stress echocardiography, and/or myocardial perfusion imaging. Few conclusions have to be take in cpnsideration. In asymptomatic treated primary prevention patients, BNP screening is able to identify existing silent cTOD. The performance of hs-cTnT was not as good as that of BNP. B-type natriuretic peptide plus hs-cTnT together performed best. Prescreening with BNP ± cTnT followed by targeted phenotyping is worth exploring further as a possible way to improve primary prevention. (Nadir MA et al. Improving the primary prevention of cardiovascular events by using biomarkers to identify individuals with silent heart disease. J Am Coll Cardiol. 2012; 60 (11):960-968).

DIETARY PATTERNS IN YOUNG ADULTS FROM TIMIS COUNTY (Abstract): Dietary patterns present at the age of the young adult have great probability to remain unchanged for the rest of the life and may contribute to eating disorders later in life. **The aim** of this study is the analysis of the intake patterns for fruits and vegetables in students from Timis County. **Material and methods:** We conducted a cross sectional study using a stratified cluster sample design to produce a representative sample of students for the Timis County. The students' sample totalized 2076 students from the universities in Timis County. **Results:** A large percent of the young people participating in the study (41.9%) does not consume fresh juices. For the consumption of fresh fruits, the present results back up the international discoveries, only 32.8% of the young people consuming fruits daily, which is a smaller percent that the medium value reported by other countries. The frequency of consumption for fruits differs according to gender, being higher for girls. For salads, the percent of young people consuming this type of foods at least once a day is 17.0%, much lower compared to 32.8% of the young people consuming fresh fruits at least once a day. **Conclusions:** The examination of the dietary patterns related to the intake of fruits and vegetables helped us to determine priority areas for future interventions. **Keywords:** FRUITS, VEGETABLES, YOUNG ADULTS, DIETARY PATTERNS

Diet and physical activity, alongside genetic factors, have important roles in determining the individual status of health. The habits related to diet and physical activity start to form during childhood and continue to shape until the adult age. While the time of childhood is characterized by resistance to new culinary experiences, the young adults will use more often new culinary products to declare their independence, not always in a beneficial manner.

In the context of the young adult distancing from the known family environment and creating a new social entourage, this will influence in a variable proportion the diet. The frequency of obesity in all age groups increased 2 to 3 times in the last two decades (1). The results of the Behavioral Risk Factor Surveillance System study (BRFSS) conducted between 1991 and 1998 show the most important increase for the obesity rates in the age group 19 to 29 years, also for those with higher educational degree (2).

Overweight and obesity are some of the most challenging and steadily rising public health problems worldwide. Strategies to effectively reduce and maintain a healthy body weight are urgently required. A number of national and international bodies recommend an increased intake of fruits and vegetables in order to decrease the risk of developing lifestyle-related diseases including overweight and obesity.

The risk-reducing effect of fruits and vegetables on overweight and obesity may in part be exerted through their possible reduction upon the total energy intake. This may be explained by various factors. Fruits and vegetables are low in energy density, high in water content and they contain a considerable amount of dietary fibers, soluble dietary fibers in particular (3).

A number of observational and interventional studies have investigated the possible association between fruit and vegetable intake and body weight. Most of these studies find an inverse association. In a review (3), emphasis is given to the role of fruits alone and the risk of developing overweight and obesity. The rationales for this are several: fruits are typically consumed at other occasions than vegetables as they can be obtained in various physical forms, such as fresh, dried, canned, pureed, making them convenient as between-meal snacks, potentially substituting more energy-dense snacks; the culinary use of fruits differs from that of vegetables. For example, because of the various physical forms and commonly sweet taste, they are suitable as deserts. Also, here they may act as the relatively healthier alternative to the traditionally more energy dense deserts and fruits are frequently consumed raw, whereas vegetables are often prepared by addition of fatty substances, which diminishes the low energy-dense characteristics of vegetables. Although, to the best knowledge of the authors, the plausible differential physiological mechanisms of fruit and vegetables have not been explored, fruits possess a distinct physical profile, which may be manifested differently in relation to body weight status. Fructose, the main sugar in fruits, has a relatively low glycaemic index (4), producing a slow increase in postprandial blood glucose followed by a possible increase in satiety. The slow absorption may also increase satiety as a result of extended contact time with the gastrointestinal receptors that produce satiety signals. Another factor that may connect fructose to satiety involves incomplete absorption of fructose with subsequent hyperosmolar environment in the colon (5). This results in attraction of fluids into the gut lumen, causing a feeling of indisposition and lost interest in further food consumption. Based on these and other as yet unknown probable factors, the authors find it appropriate to distinguish between fruits and vegetables in relation to overweight and obesity (3).

Previous literature revealed that young adults tend to consume excess amounts of total fat, saturated fat, cholesterol and sodium. Other studies have found inadequate intakes of essential micronutrients, such as calcium, iron, zinc, folate, and vitamins A, B_6 and C, as well as low consumption of fruits and vegetables. Promotion of dietary change among young adults, who are currently healthy, could be especially challenging. Potential future health benefits of a balanced diet, which are the principal emphases in many of the current guidelines, may not seem as appealing to this particular population as immediate physical and psychological benefits (6).

The aim of this study is to analyze dietary patterns among young adults from the urban area in Timis County.

MATERIAL AND METHODS

This study is based on the grant "The evaluation of risk behavior dimension in high school students and young people from vocational schools and universities in Timis County" (CORT 2004), carried out between 2003-2005, cod CNCSIS 1167, attained at The University for Medicine and Pharmacy Timisoara. The CORT 2004 study is a transversal epidemiologic survey assessing risk behavior in a group of young people attending the colleges and universities in Timis County.

We conducted a cross-sectional study using a stratified cluster sample design to produce a representative sample of students for the Timis County, Romania. A 126-item questionnaire was developed to investigate health-risk behaviors of young adults. Some of the questionnaire items were modified from other instruments, including the 1999 Youth Risk Behavior Survey (YRBS) (7) and the European School Survey Project on Alcohol and Other Drugs (ESPAD) (8). The survey focused on health risk behaviors established during the period of young adulthood that results in the most significant mortality, morbidity, disability, and social problems for youths and, later, adults. The following issues were examined: family environment, out-of-family entourage, tobacco use, alcohol use, illicit drug use, violence-related behaviors and school-related violent behaviors, suicide ideation, attempted suicides, and the seriousness of those attempts, preventive conduct in road traffic, sexual behaviors, dietary behaviors, overweight and weight control, physical activity, medical attendance. In total, 30 items were dedicated to dietary behaviors. A pilot test was conducted to establish the validity and reliability of the instrument.

The participants were included in this study based on their free consent. The questionnaire was administered in a regular classroom setting and took students 60 minutes to complete. No filter questions were used. By doing this, comparable amounts of time are required to complete the questionnaire, regardless of risk behavior status and students cannot detect the risk behaviors of their colleagues simply by looking at the pattern of the responses. Only students present the day of the survey were eligible for participation. Trained public health residents and undergraduate students conducted the survey. The data collectors read aloud scripts that explained the survey procedures. Students were told that they do not have to put their names on answer sheets, and that obtained data would be used only for general assessment of the situation in the county.

The data processing and interpretation used modern methods of advanced medical statistics. Data were filed using *EpiInfo*, version 6.0, 2001 and processed using *EpiInfo*, version 3.5.1, 2008. The values of the statistical significance level $p<0.05$ were considered statistically significant, and $p<0.01$ were considered very significant statistically. The following statistical tests were applied: chi-square test, Mann-Whitney test, Kruskal-Wallis test, Pearson correlation and Kendall correlation. Factorial exploratory analysis was also used in order to group the association of the risk behaviors.

RESULTS AND DISCUSSION

The students sample from Timis County

was composed of 2076 students from universities in the urban environment. Among this sample, the distribution was as it follows: 62.49% (1296) girls and 37.51% (778) boys. The individuals participating in this study were young adults, meaning their age was between 18 years (0.3%) and 25 years (3%).

In Great Britain, in the year 1994, the Cardiovascular Review Group recommended a daily intake of 5 to 6 portions of fruits and vegetables, twice as much as the medium intake of the average British citizen, although the consumption pattern vary in different areas and in different social layers (9). Among multiple factors influencing the intake of these food classes, the pleasure of consuming them is one of the most important internal factors, and their availability, cost and time necessary for cooking them are maybe the most important external factors (10). For people leading an active life reaching the recommended ratio of these foods may be challenging. One way to consume them during the day is in the form of juice.

As to the intake of fresh fruits juices, most of the young people participating in the study declared they do not consume it, 41.9% (858), or they consume it 1-3 times per week, 37.9% (775). Only 7.1% (145) admitted they drink fresh fruits juices once a day, and 5.5% (113) twice or more times per day. The contribution of fruit juices to the fibers intake is very poor and in this aspect it is more indicated the intake of fresh fruits (tab. I).

The studies conducted on national level in the United States showed that young adults with the age between 18 and 24 years consume insufficient quantities of fruits and vegetables (11, 12, 13).

TABLE I

The students' distribution according to the frequency of consumption for juices prepared from fresh fruits

The frequency of consumption for juices prepared from fresh fruits	Frequency	Percent	Valid percent	Cumulated percent
2 or more times per day	113	5.4	5.5	5.5
Once per day	145	7.0	7.1	12.6
4-6 times per week	156	7.5	7.6	20.2
1-3 times per week	775	37.3	37.9	58.1
never	858	41.3	41.9	100.0
Total	2047	98.6	100.0	
Missing data	29	1.4		
Total	2076	100.0		

The studies conducted by WHO uncovered that, on average, only 30% of the boys and 37% of the girls report daily fruits intake. The consumption was highest in Israel (49% of the boys and 54% of the girls) and lowest in Estonia (17% of the boys and 23% of the girls). In 16 different countries and regions, more than 25% of

the young people consume only rarely fruits (once per week or less). In almost all the countries and regions, mostly girls reported daily fruits intake, although there is a considerable geographic variation present (14).

Of the young adults participating in the present study, 41.13% (844) reported fruits intake 1-3 times per week, and 23% (472) consume fruits 4-6 times per week. Only 3.07% (63) of the participants to this study declared they never eat fruits. 16.0% (329) of the young adults included in the study eat fresh fruits 2 or more times per day, intake pattern comparable to the international recommendations (tab. II).

TABLE II

Students' distribution related to the frequency of intake for fresh fruits

Frequency of intake for fresh fruits	Frequency	Percent	Valid percent	Cumulated percent
2 or more times per day	329	15.8	16.0	16.0
Once per day	344	16.6	16.8	32.8
4-6 times per week	472	22.7	23.0	55.8
1-3 times per week	844	40.7	41.1	96.9
Never	63	3.0	3.1	100.0
Total	2052	98.8	100.0	
Missing data	24	1.2		
Total	2076	100.0		

The results of the present study corroborate the results of other international studies showing that most of the young people do not consume the recommended quantities of fruits (15, 16).

The sample of 844 young adults reporting fruits intake 1-3 times per week, is composed of 497 girls (38.7% of the female respondents) and 347 boys (45.4% of the male respondents). For the different fresh fruits intake frequencies, the males and females percents are similar. Nevertheless, the girls' percent, 17.4% (223) is higher than the boys' percent, 15.7% (120), which consume fresh fruits once per day. The same, in case of consumption 2 or more times per day of these aliments, the percent of girls reporting this intake pattern, 18.2% (234), was higher than the boys percent, 12.4% (95) (tab. III). These results suggest that the consumption frequency for fruits differs related to gender, being higher for girls, conclusion reached by other authors too (16).

Salads are consumed by the young adults: 52.0% (1067) 1-3 times per week, 16.8% (345) never, and 6.3% (130) consumes salads 2 or more times per day, but in this case also the intake is low (tab. IV).

In the fast-food restaurants accessible to students, there is a less diversified offer of salads, and for the most part they are missing. As the young adults prefer this way to procure food, the reduced intake of these foods can be explained.

TABLE III

Students' distribution according to the fresh fruits frequency of intake, by gender

Fresh fruits frequency of intake	sex				Total	
	female		male			
	Number	Percent	Number	Percent	Number	Percent
Twice or more times per day	234	18.2	95	12.4	329	16.0
Once per day	223	17.4	120	15.7	343	16.7
4-6 times per week	301	23.4	170	22.2	471	23.0
1-3 times per week	497	38.7	347	45.4	844	41.2
Never	30	2.3	33	4.3	63	3.1
Total	1285	100.0	765	100.0	2050	100.0

TABLE IV

Students' distribution related to the salads intake frequency

Salads intake frequency	Frequency	Percent	Valid percent	Cumulated percent
Twice or more times per day	130	6.3	6.3	6.3
Once per day	219	10.5	10.7	17.0
4-6 times per week	290	14.0	14.1	31.2
1-3 times per week	1067	51.4	52.0	83.2
Never	345	16.6	16.8	100.0
Total	2051	98.8	100.0	
Missing data	25	1.2		
Total	2076	100.0		

CONCLUSIONS

Dietary patterns may seem not as acute a risk behavior compared with behaviors producing more dramatic results (violence, addiction etc.), but on a long term is just as damaging as the others. There are always difficulties in adequate assessing nutrition intake with a limited number of items.

The present study corroborates the findings of other authors, namely the young adults' intake of fruit and vegetables is lower than the recommended ratio. There are a number of reasons we can think off in order to explain this situation: the students prefer to eat in fast-food restaurants, where the offer for fresh salads and fruits is usually not very diversified; the cost of these foods can represent a barrier to higher intake because they are more expensive than highly processed foods; during an active

day it may be difficult to consume these particular aliments (an option is represented by juices); fruits are usually ready to be eaten, but vegetables necessitate more time to prepare; the food choices are usually influenced by entourage and publicity.

The insufficient intake of fruits and vegetables situates the young adults at risk for future chronic diseases (cardiovascular diseases, diabetes, obesity). In the future, strategies to increase the intake of fruits and vegetables must be developed for this age group, taking into account the particularities of the young adults.

LEFT-SIDED DUPLICATION OF INFERIOR VENA CAVA: CLINICAL IMPLICATIONS IN A PATIENT WITH SIGMOID ADENOCARCINOMA

2. Center of General Surgery and Liver Transplant

LEFT-SIDED DUPLICATION OF INFERIOR VENA CAVA: CLINICAL IMPLICATIONS IN A PATIENT WITH SIGMOID ADENOCARCINOMA (Abstract): Double inferior vena cava is a rare congenital anomaly, usually detected by computed tomography or magnetic resonance imaging. Although asymptomatic, it may have a clinical significance, as it may mimic a para-aortic lymphadenopaty. A case of left-sided duplication of the inferior vena cava in a patient with sigmoid colon cancer is presented. The diagnostic pitfalls and clinical implications are discussed. Accurate preoperative assessment of such an anatomical variant is of utmost importance, this way potentially life-threatening surgical complications, particularly when a minimally invasive approach is planned, are prevented. **Key words**: DOUBLE INFERIOR VENA CAVA, COLON CANCER, LYMPHADENOPATY, COMPLICATIONS.

Congenital anomalies of the inferior vena cava are uncommon findings (1) and usually are identified in asymptomatic patients (2). Although rare, double inferior vena cava may have a significant clinical impact, especially during retroperitoneal surgery (3, 4) or in the treatment of thromboembolic diseases (5). The left inferior vena cava can be misinterpreted as a retroperitoneal tumor or, more frequently, as a para-aortic lymphadenopaty (7, 8). We present the case of a patient with sigmoid colon adenocarcinoma and a double inferior vena cava, the left one mimicking a lymph node metastasis. The clinical implications of this association are also discussed. To the best of our knowledge this is the first case reported in the English literature on an association between colon cancer and double inferior vena cava.

CASE REPORT

A 48-year-old woman with no significant medical history was investigated for alternating constipation and diarrhea along with abdominal discomfort. Clinical examination was unremarkable, except mild skin pallor. Laboratory tests revealed mild anemia (Hb = 9 g/ dl) without other abnormalities. Carcinoembryonic antigen and CA 19-9 serum levels were within normal limits. Colonoscopy emphasized a ulcerate tumor mass at the level of the sigmoid colon, partially obstructing the lumen. Abdominal ultrasonography revealed a para-aortic "tumor mass" suggestive of lymphadenopaty. Axial contrast enhanced computed tomography showed a double inferior vena cava (fig. 1 a), invalidating the presence of para-aortic lymphadenopaty; no distant metastases to the liver, lung or peritoneum

were found. Coronal computed tomography reconstruction revealed a left accessory inferior vena cava lying along the left side of the aorta and draining into the left renal vein (fig. 1 b). The patient was referred to surgery and underwent a left open colectomy. The double inferior vena cava was confirmed intraoperatively (fig. 2). The postoperative outcome was uneventful and the pathological examination of the operative specimen diagnosed a moderately differentiated (G2) sigmoid adenocarcinoma invading through the muscularis propria into the pericolic tissue (pT3), with no regional lymph node metastases (pN0) – stage IIA, Dukes B.

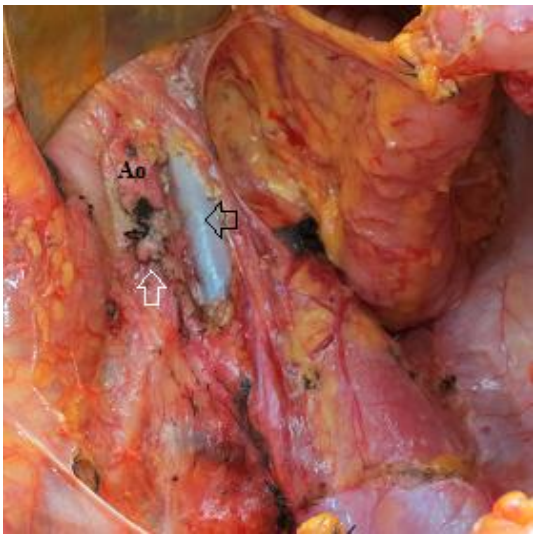

Fig. 1. (a) Axial contrast enhanced abdominal computed tomography showing a pseudotumoral mass on the left side of the aorta (black arrow); (b) Coronal contrast enhanced reconstruction imaging revealed double infrarenal inferior vena cava; the left inferior vena cava (black arrow) continues the left common iliac vein and drains into the left renal vein (Ao, aorta; rIVC, right inferior vena cava; lrv, left renal vein; SMA, superior mesenteric artery)

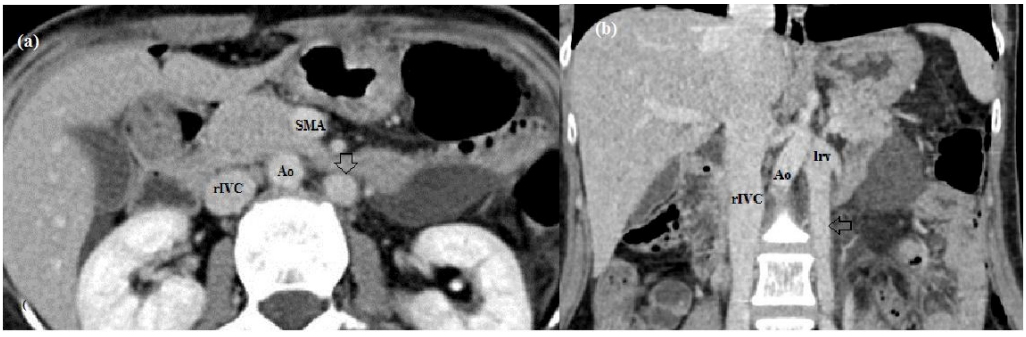

Fig. 2. Intraoperative aspects of the left inferior vena cava (black arrow) after left colectomy with removal of the lymph nodes at the origin of the inferior mesenteric artery from the aorta (Ao); white arrow shows the stump of the inferior mesenteric artery

DISCUSSION

The prevalence of double inferior vena cava in the general population is no more than 3% (1), most of the cases being asymptomatic and diagnosed by radiology (2, 8). However, in a limited number of cases, this rare anatomical variant may have a surgical impact, especially in urology (7, 9) or vascular surgery (4).

The embryogenesis of the inferior vena cava is a complex process. Development of the inferior vena cava is due to appearance, regression, and fusion of three paired embryonic veins: posterior cardinal, subcardinal and supracardinal veins. Normally, the left supracardinal vein regresses, and the right supracardinal vein forms the infrarenal part of the inferior vena cava (1, 2). Persistence of the left supracardinal vein results in a double infrarenal vena cava; usually, the left infrarenal vena cava ends into the left renal vein (1, 2), as seen in the above presented case.

Data in the literature show that double inferior vena cava was misdiagnosed as para-aortic lymphadenopathy in patients with prostate (7), testicular (9), cervical (10) or rectal cancer (8). Thromboses of the double inferior vena cava (6) have been reported. CT scan without the administration of a contrast agent is the most common cause of misdiagnosis (6).

Lymph node metastases are widely recognized as one of the most important prognostic factors after colon cancer resection. Recently it was demonstrated that the presence of lymph node metastases at the origin of inferior mesenteric artery from the aorta strongly correlates with poor prognosis (11). Thus, the identification of a para-aortic lymphadenopathy in sigmoid colon cancer is of utmost diagnostic importance. This is particularly important when a minimally invasive surgery is planned because in these cases there is a poor depth perception, and tactile sensation is diminished (12). Misinterpretating a left inferior vena cava as a lymph node metastasis may lead to such life-threatening complications as severe intraoperative hemorrhages. Nevertheless, laparoscopic approach has been previously demonstrated as feasible and safe in left nefrectomy patients, even in the presence of a double inferior vena cava (3).

A double inferior vena cava was also associated with an increased risk for deep vein thrombosis, especially in young adults, due to inadequate venous return from the lower extremities (5).

The clinical implications of a double inferior vena cava in a patient with colon cancer are related to an increased risk for deep vein thrombosis and misdiagnosis of para-aortic lymphadenopaty. An accurate preoperative diagnosis can be made if computed tomography assessment of vascular structures is made by using intravenous contrast material; during the arterial phase, the veins exhibit little or no contrast (2). Prophylactic use of anticoagulants may theoretically reduce the risk for deep vein thrombosis and pulmonary embolism.

CONCLUSIONS

Double inferior vena cava is a rare congenital anatomical variant that may have significant surgical implications. Awareness of this anomaly is mandatory and the surgeon should be able to distinguish it from para-aortic lymphadenopaty. If a double inferior vena cava is not preoperatively recognized, it can be a source for severe surgical complications.

ASSESSMENT OF METEOROLOGICAL FACTORS INFLUENCE ON THE HEALTH OF A GROUP OF PATIENTS IN THE CITY OF IASI (Abstract): **Aim**: Analyzing the meteorological factors influence perception on state of health and evaluation of the awareness of how they act **Material and methods**: The study was carried out between 2010-2011 on a sample of 75 patients from of a cabinet of family medicine în the city of Iasi. The lot included randomly selected persons with age between 18-74 years. They answered a questionnaire with 25 items. The questionnaire Included demographic date (age, education, social, financial situation, the belonging religious) and questions on personal perception and evaluation of the influence of climate and weather conditions on individual state of health, degree to promote beneficial climatic factors în maintaining health and quality of life. **Results**: The istribution of Cases în function of perception implication în meteorological factors în health reveals the following aspects: they showed significantly morecases meteorosensibili from urban areas (45.3%) and meteoro dependentecases from rural areas (10.7%) în our group has revealed several casesmeteorosensibile both females (36%) and the male ones (14.7%) Distribution în the study group depending on the class of diseases revealed predominant rheumatic diseases (36%) and heart disease (33.3%), haematological (20%) mental illness (14.7%) digestive (12%),respiratory diseases and neurological (10.7%). **Conclusions** Meteorological facts does not represent etiological but the favoring or triggering factors în some pathological conditions. Important weather newsletters în informing and educating patients about the risks of meteorological sesnsibili requires that a necessity for maintaining health andquality of life. **Key words**: METEOROLOGICAL SENSITIVE, METEOROLOGICAL ADAPTATIV, ANTICIPATIVE, METEOROLOGICAL DEPENDENT.

Studiile privind impactul factorilor meteorologici asupra stării de sănătate au evidențiat că meteorosensibilitatea interesează aproximativ 1/3 dintre locuitorii zonelor cu climă temperată, manifestând tropism la schimbările vremii. Diagnosticul meteoropatiilor se stabileşte cu dificultate deoarece nu se poate separa acțiunea factorilor meteorologici de întreg complexul de agenți etiologici şi de a separa reacțiile somatice de cele psihoemoționale.

Experții francezi au realizat un studiu de durată, computerizat, care a demonstrat că incidența infarctului de miocard creste în perioadele friguroase, în vreme ce seceta şi canicula din timpul verii favorizează apariția atacului vascular cerebral, exprimat prin pierderea bruscă a cunoştinței şi a

motilității active. De asemenea s-a constatat că atunci când temperatura zilei scade cu 10 grade, frecvența cazurilor de infarct crește cu 13% iar când presiunea atmosferica se modifică cu 10 milibari, rata crește cu până la 12%. Astfel de studii s-au efectuat în mai multe țări din Europa occidentală şi majoritatea au confirmat aceste observații. (1). Cercetări efectuate în Suedia au relevat faptul că migrenele sunt mai accentuate în urmatoarele trei zile după sosirea unui front atmosferic, însoțită de o schimbare bruscă a temperaturii şi presiunii atmosferice iar cercetările efectuate în Japonia au evidențiat faptul că astmul are crize frecvente când vântul îşi schimbă direcția. Un studiu efectuat în Ungaria în cadrul companiei de transporturi auto „Volan Trust", a arătat că variațiile condițiilor atmosferice proprii în special primăverii şi toamnei, generează migrene, oboseală, somnolență sau, dimpotrivă, încordare. Fenomenele constatate la schimbarea vremii afectează în mod nedorit eficiența şi siguranța în trafic a conducătorilor auto. Un studiu similar efectuat la celebrele uzine Mercedes-Benz din Stuttgart, Germania, asupra unui număr de 36.000 de accidente de muncă, a pus în evidență influența fronturilor de aer cald, însoțite de instabilitatea atmosferică, în producerea accidentelor de la locul de muncă. Un alt aspect a fost surprins de únele studii americane efectuate în unitățile de învământ. Concluziilor acestora au arătat că scăderea marcată a presiunii atmosferice este însoțită de diminuarea disciplinei în şcoli, în vreme ce valurile de caldură, merg mână în mână cu creşterea violenței urbane. Studiul unui un front atmosferic care a ucis mii de oameni în Chicago, a evidențiat că nu doar valul de căldură a fost cauza deceselor, ci faptul că a existat o asociere de factori care ar fi putut agrava activitatea cardiacă, concluzionându-se ca fenomenele meteorologice reprezintă factori dinamizatori - favorizanți pentru unele procese patologice (2,3,4).

Studiul nostru a avut următoarele obiective: (i) analizarea implicării factorilor meteorologice în starea de sănătate individuală; (ii) evaluarea percepției subiective, cognitive şi emotionale a influenței factorilor meteorologice în starea de sănătate şi starea de boală individuală şi (iii) evaluarea implicării personale în promovarea factorilor meteorologice în menținerea stării de sanatate şi în prevenirea şi combaterea stării de boala

MATERIAL ŞI METODE

Studiul a fost efectuat în perioada 2010-2011, pe un lot 75 de pacienti ai unui cabinet de medicină de familie din municipiul Iasi. S-au respectat principiile etice de cercetare, pacienții fiind informați cu privire la metoda cercetării şi şi-au exprimat consimțământul. Lotul selectat aleator a cuprins persoane cu vârste între 18 şi 74 de ani. Aceştia au răspuns unui chestionar cu 25 itemi care a inclus date demografice (varsta, sex, studii, mediul social urban/rural, situație financiară, religie) şi întrebări privind percepția şi evaluarea personală a influentei climei şi condițiilor meteorologice asupra stării de sănătate individuală, a gradului de promovare a factorilor climatici sanogeni în mentinerea sănătății şi a calității vieții. Prelucrarea datelor s-a efectuat cu ajutorul programului SPSS 16.0

REZULTATE şi DISCUTII

1. *Caracteristicile lotului de studiu*. Lotul de 75 de pacienti, a inclus 45 (60%) femei şi 30 (40%) bărbați cu un raport F/M= 1,5/1. Au predominat cazurile de sex femi-

nin provenite din mediul urban (48%), însă diferența nu a fost semnificativă statistic față de masculin (32%) comparativ cu distribuția cazurilor din mediul rural (F=12% vs M=8%) (χ^2=0,09; GL=1; p=0,768).

Vârsta medie a pacienților la intrarea în studiu a fost de 42,91 ± 14,50 ani, variind de la 18 la 74 ani: vârsta medie a pentru sexul masculin a fost de 39,67 ani cu variații de la 18 la 68 ani; iar cel feminin de 44,13 cu variații între 19 şi 73 ani.

Nivelul de instrucție determină conştientizarea implicării factorilor sau condițiilor meteorologice în definirea stării de sănătate şi a calității vieții a evidențiat ca 40% au avut nivelul liceal; 33,3% studii superioare; iar 26,7% studii medii. Lotul de studiu a cuprins semnificativ mai multe femei cu nivel mediu de instrucție comparativ cu bărbații (p=0,008); mediul de proveniență a fost preponderent urban la persoanele cu nivel mediu de instrucție (p=0,008); nu s-au înregistrat diferențe cu semnificatie statistica pe grupuri de vârstă (5)

Activitatea profesională a evidențiat existenta a 56% salariati iar 33,3% erau pensionare. Analizarea condițiilor socio-economice din momentul intrării în studiu a evidențiat: condiții nesatisfăcătoare: 15 (20%) - cu venitul lunar mediu de 600 ron;condiții satisfăcătoare: 40 (53,3%) – cu 1000 ron;condiții bune: 15 (20%) - cu peste 1000 ron; 6,7% dintre pacienți nu au precizat venitul familiei.

2. Distribuția cazurilor în relatie cu *percepția cognitiv-emoțională a implicațiilor factorilor de mediu în starea de sănătate* a relevat existenta mai multor cazuri meteorodependente provenite din mediul rural (10,7%) şi meteorosensibili din mediul urban (45,3%); s-au evidențiat mai multe cazuri meteorosensibile atat la sexul feminin (36%), cat şi la masculin (14,7%); la grupul de vârstă de 18- 30 s-au înregistrat diferențe semnificative comparativ cu grupul de grupa de peste 65 ani, unde au fostsemnificative: la grupul 31-65 ani predomină persoanele meteorosensibile (40%) la grupul de peste 65 ani au predominat cazurile meteorodependente (9,3%) (tab. I).

TABELUL I

Digestive	7	77,8	2	22,2	χ^2=0,29; GL=1;p=0,587

[a]pentru valorile mai mici de 10, proportiile sunt orientative

4. Analizarea *evolutiei simtomatologiei* pe grupuri de afecțiuni corelat cu modificările de vreme diferențele procentuale semnificative au următoarele caracteristici: afectarea cardiovasculară prezintă un risc relativ de 2,47 ori mai mare la pacienții meteoroinfluențabili (p=0,019); afectarea aparatului respirator este asociată semnificativ cu pacienții meteoroinfluențabili (p=0,023); afecțiunile sistemului osteoarticular, în asociere cu factorii de mediu prezintă un risc relativ de peste 11 ori mai mare la pacienții meteoroinfluențabili (p=0,0007); afectarea psihică este dependentă semnificativ de variațiile factorilor meteorologici, cu un risc relativ de aproximativ 6 ori mai mare la grupul de pacienți meteoroinfluențabili (0,015); afecțiunile neurologice sunt asociate pacienților meteoropați, la impactul cu variațiile factorilor meteorologici (p=0,023), riscul relativ fiind de peste 5 ori mai mare la aceştia; sindroamele anemice sunt caracteristice pacienților meteoropați, cu un

risc relativ de 9,51 (p=0,00006); prezența bolilor metabolice, digestive, de piele, renale şi chiar cancerele nu s-au asociat semnificativ cu variațiile factorilor de mediu.

5. Evaluarea *cunostintelor* legate de efectul sanogen (6) al factorilor climatici în mentinerea starii de sanatate şi în prevenirea şi combaterea starii de boala din cei 75 de pacienti intervievati doar 26,7% consulta prognozele meteo; cunoaşterea şi promovarea factorilor climatici în starea de sănătate s-a regăsit la 36% din pacienți; 46,7% dintre cazuri au beneficiat de tratamente în stațiuni balneoclimaterice şi 72% nu cunosc eficiența terapeutică a salinelor.

CONCLUZII

Cercetările noastre au evidențiat ca implicarea factorilor meteorologici în promovarea sănătății şi combaterea stărilor de boala este insuficient cunoscut şi valorificată iar fenomenele meteorologice s-au dovedit a fi factori dinamizatori favorizanți pentru unele procese patologice.

S-a dovedit dificultatea de stabilire a diagnosticului meteoropatiilor existând dificultate în a separa acțiunea factorilor meteorologici de întreg complexul de agenți etiologici şi de a diferenția reacțiile somatice de cele psihoemoționale.

Educarea pacienților asupra riscurilor meteorotrope a fost evidențiată ca principală preocupare pentru medicul de familie.

LASER MICRODISSECTION – A NOVEL APPROACH FOR ACCESSING THE MOLECULAR BASIS OF CANCER (Abstract): **Background and aim:** It has been known for quite a lot of time that tumours are cellular aggregates of different cells, mainly malignant cells but also immune cells – of which the most well-known are the tumour infiltrating lymphocytes (TIL) and the tumour associated macrophages (TAM). By observing hematoxylin – eosin stained or immunohistochemical stained slides belonging to different areas of the tumour it is clear that there are clusters of malignant cells within the tumour itself that seem to behave differently from the rest of the tumour. Another fact is that different areas of the tumour contain different inflammatory cells which may promote carcinogenesis or may help to confine it. Whereas different immune cells can be recognised by using immunohistochemistry, a satisfactory characterization of the molecular characteristics of the malignant clusters of the tumour cannot be made without further use of different molecular techniques such as different PCR techniques or microarray methods. Laser microdissection thus comes as a valuable aid in choosing exactly which cells will be analyzed further on. **Principle of the method:** Laser microdissection is based on using the energy of a focused laser beam to cut through the thickness of the tissue that is placed on a microscope slide in order to obtain cell samples previously selected by the pathologist through special software. **Conclusion**s: To be able to cut the cells that you want and analyze them further without having them contaminated with other cells means that you can get more insight into the progression of the mutations that occur in these malignant cells, mutations that cause them to become more aggressive or multidrug-resistant. This could in time lead to the discovery of new molecular targets for cancer therapy. **Key words**: LASER MICRODISSECTION, LASER PRESSURE CATAPULTING, CELL CLUSTERS, MOLECULAR ANALYSIS.

Much of the current scientific focus in medical sciences has nowadays shifted on gathering information about the pathogenesis of the disease at a molecular level. The reason for this increasing interest regarding the molecular characteristics of cancer cells has to do with trying to find new approaches for cancer treatment.

A "top-down" strategy for gathering and integrating information about various factors

that could influence the prognosis of the tumour or the treatment should include the assessment of the histological type of the tumour, followed by the analysis of the tumour microenvironment and finally the molecular alterations responsible for the development of the tumour. Such an analysis could lead to a better understanding of the factors that play a role in determining a tumour's outcome and can complete the prognosis issued by the TNM staging thus leading to better patient management.

There has been a lot of struggle to find a good tool for selecting only some of the cells that are of particular interest to the researcher. It is widely known that a tumour mass consists of different cell clusters, belonging to different cellular clones. Sometimes these clusters are clearly defined from one another even on hematoxylin-eosin stained slides and the study of these cells alone, without their neighbouring cells could be interesting from the point of view of discovering the more intimate mechanisms that lead to metastasis, multidrug-resistance, local relapse or more precisely the mechanisms that lead to the selection of clones that induce these effects.

High throughput methods for molecular studies have become available but despite the increasing complexity of these new methods their accuracy is influenced by the selection of the study material (1, 2). For many types of assays the use of homogenised tissue samples can result in evening-out the results because of mixing cells that are heterogeneous in nature. The reasons behind this is the fact that all human tissues and especially malignant tissues are mixtures of different cell types from which procuring a pure sample may help to acquire meaningful data.

The concept of tumor heterogeneity is increasingly being recognized, and it will be important to define and analyze separately subpopulations of cells within a neoplasm to identify properties that might be unique to them.

Some of the techniques that have been used so far in attempting to isolate pure cellular populations are cell cultures, flow cytometry and different microdissection techniques. Each of them has proven to be useful to a certain extent. Flow cytometry for example is a technique that has been used extensively, but it comes with the disadvantage of having to use a suspension of cells and this means it has limited usefulness in studying solid tumors.

Cell cultures are another example that has limited applicability because of the fact that cells being cultivated although belonging to a cell line that is of interest to the researcher do not grow in the exact same environment that the tumor does. This means that they are not subject to the same selection pressures and accordingly they may be unfit for some research purposes. For example there have been reported differences in gene expression between primary colon cancer cells and cultivated cell lines (3).Early research had focused on grafting tumor tissue on laboratory animals but this technique has been abandoned due to it being expensive and time consuming.

We mentioned earlier the use of some microdissection techniques, the most rudimentary of which involved using a fine needle to scrape off the tissue of interest from a histological section (4). An advanced version of this technique is the non-laser based microdissection – a technique that uses a piezoelectric micro-chisel that vibrates to ultrasonic frequencies (5). Yet another improvement to the technique above is a system that uses a micromanipu-

lator for extracting single cells suitable for single-cell PCR (6).

Another technique that was used was coating the cells of interest with a pigment that prevents ultraviolet light from destroying the DNA of the cells of interest and then subjecting the whole tumor section to ultraviolet light (7). By the use of this technique cellular studies could be performed only on the genetic material of the cells that were of interest for the researcher.

The most intensively used microdissection technique currently applied is laser capture microdissection.

THE PHYSICAL PRINCIPLE BEHIND LASER CAPTURE MICRODISSECTION

Laser capture microdissection is "a recently developed technique that allows the rapid and reliable procurement of pure populations of cells from tissue sections, in one step, under direct microscopic visualization" (8). This method was developed at the National Cancer Institute (NCI) for the analysis of populations of cells from tumors. A commercial instrument, developed by NCI and Arcturus Engineering Incorporated (Mountain View, California, USA), became available within 12 months of the first publication that described the method(9).

The principle underlying LCM is simple. It involves cutting the cells that are of interest to the researcher by means of a laser beam coming from a laser generator that is coupled into the microscope. The laser beam cuts away the sections previously selected by the pathologist either by the movement of the laser beam or by the movement of the microscope's stage. The setup can involve either an inverse microscope or a normal one, depending on the means by which the sampled cells are transferred into the PCR tubes (8).

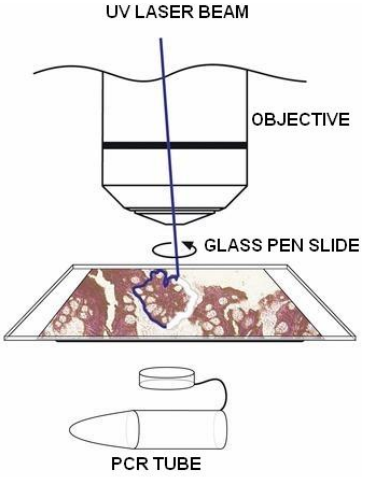

Fig. 1. Schematic representation of a laser microdissection system in which the dissected sample is collected through gravity - adapted from the Leica official website (10).

Lasers used are either ultraviolet (UV) or infrared (IR). The UV spectrum can be split into three regions UV-A, UV-B and UV-C. The absorption peaks of biomolecules such as DNA is located somewhere between 260 and 280 nm – which corresponds to UV-C. This is one reason why UV-A is used in laser microdissection. Another reason for using UV-A laser is better spatial resolution. This why 355 nm is the wavelength of lasers being used in most of the commercially available laser microdissection systems. When compared to IR lasers, UV laser have the advantage of being faster and able to cut through thicker sections. However UV lasers could supposedly produce lesions when very small cells are cut due to the high energy that they produce. Compared to UV laser, IR laser has the major advantage of being less harmful to the dissected cells, but has

the great disadvantage of being slower and requiring special slides.

The energy of the lasers being used is important considering the fact that section thickness or hardness is variable (5 – 20µm sections can be processed by laser microdissection) (8). This is the reason why the newest laser microdissection systems offer adjustable energy lasers. Besides the energy of the laser, the pulse duration is important because shorter pulse duration means faster and more precise cutting by depositing strongly localized energy at well-defined locations. The laser beam is focused through the lens system into a micron-size spot diameter that allows the laser beam to carry enough energy in order to cut through the tissue.

The transfer of the selected cells can be done by so-called contact methods or by contact-free methods. In the first instance histological sections that are to be processed using this method have to be placed on specially designed slides covered with ethylene vinyl acetate (EVA). The reason why the EVA film is used is that when this material interacts with the laser beam it melts and fuses to the area of the slide that is intended to be removed. The selected cell or cell group fused with the EVA film is then removed and further processed. When using this method the EVA film is placed on the cap of a PCR tube. This is the original laser microdissection method described that was using IR laser. The need for these special caps is one of the major disadvantages of using IR laser (8).

There are some other contact methods that use different adhesive plastic films, but all these methods have the disadvantage of possible contamination with foreign material.

Another group of transfer methods are contact – free and they involve using gravity or different "catapulting" technologies. The easiest of these methods is based on letting the sample fall into the cap beneath under the influence of gravity. This method requires the use of an upright microscope and PEN (polyethylene naphthalate), PET (polyethylene terephthalate) or POL (polyester) membrane slides.

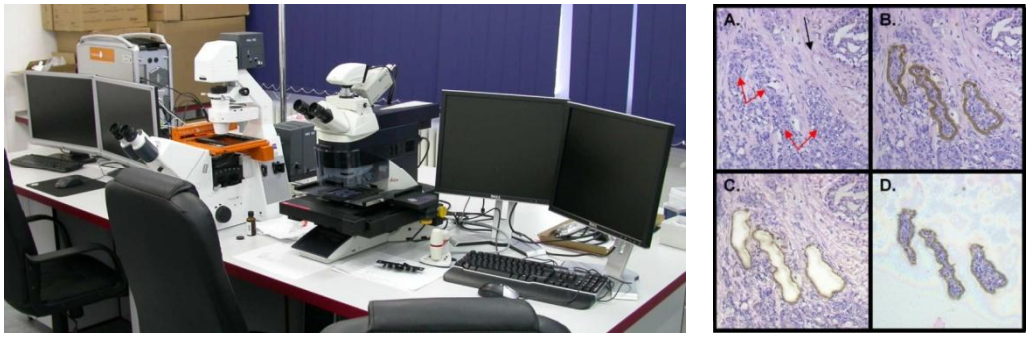

Fig. 2. The Leica LMD6000 microdissection system available in the Genetics and Immunology Laboratory -"Sf. Spiridon" Hospital, Iaşi and the steps involved in laser microdissection (A. visualization of the slide in order to chose the cells that could be of interest; B. selection of the cells; C. view of the slide after microdissection. D. microdissection product) (11).

Other contact-free methods are based on different "catapulting" technologies. The first of them is a method that is already implemented and is based on laser pressure catapulting. The principle behind laser pressure catapulting has been asserted by Schütze et al in 1998 and confirmed by Niyaz et al in 2005 (12,13). To allow the sampled cell or group of cells to be lifted out of the plane of the slide a laser beam is focused below the focal plane of the sample through an objective with high numerical aperture. The power generated by this unfocused laser beam can lift the selected cells out of the object plane and transports them along the axis of the beam (14).

In order to have a more in depth understanding on how laser pressure catapulting works we have to stress the fact that the way in which a laser beam interacts with tissue depends on some characteristics of the tissue and the laser: absorption characteristics of the tissue, wavelength, numerical aperture of the objective, whether or not the laser is pulsed. The way in which laser energy is used to cut tissue has been investigated by Vogel and Vengupalan and they concluded that laser pressure catapulting relies on plasma formation supported by linear absorption of energy that leads to mechanical effects such as cavitation or shock wave formation (15). The process takes a minute interval of time that should be short enough not to affect other cells situated in the proximity of the targeted cells (16, 17, 18).

The newest transfer method that involves the use of laser is LIFT (Laser Induced Forward Transfer) – a method that involves the transfer of minute quantities of material as droplets and their deposition on another surface (19).

APPLICATIONS OF LASER MICRODISSECTION SYSTEMS

By the use of this system cells can be selectedbased on their morphology, on immunohistochemical staining or by using in situ hybridisation methods to select cells with a specific genotype. Immunohistochemistry is the basis of a novel microdissection technique – expression microdissection. After immunohistochemical staining a special film is applied to the slide and the whole slide is then irradiated by a light or laser source. When the film is removed the positively stained cells are removed along with it because they become adherent to the film after the irradiation process. Such a system is virtually an operator-independent system that can be used by a researcher with minimal or no histopathology training (20).

Laser microdissection is currently being used on a variety of substrates: living cells, frozen sections of tissue, but most importantly it can also be used on formalin fixed, paraffin embedded sections. The fact that it can be used on such paraffin embedded sections makes laser microdissection an important tool for analyzing archived pathological material.

After the dissection process takes place the genetic material of the cell has to be extracted. For DNA extraction proteinase K is used. PCR can then be performed on the resulting DNA and finally the DNA can be sequenced or it can be used in Southern blotting (21).

One problem with using DNA material from paraffin embedded tissue is that the use of formalin fixation leads to a certain degradation of the genetic material which is traduced into a smaller amount of amplification product at the end of the PCR process compared to frozen tissue. Because of this a

methanol fixation method was proposed before the paraffin embedding. The results of using methanol instead of formalin have been investigated by Maitra et al who have shown that the DNA obtained from samples fixed by their protocol could amplify products up to 989 base-pairs compared to only 268 base-pairs when the DNA was obtained from formalin fixed samples (22). Such DNA samples can then be used in loss of heterozygosity studies or single strand conformational polymorphism assays.

DISADVANTAGES OF THE METHOD

The major disadvantage especially in the current economic climate of our country is price. Besides the initial sum that has to be invested in buying the system one must take into account the need for special slides which can be considered costly compared to slides that are used in normal microscopy for example.

Most of the other disadvantages come from the fact that the procedure requires a researcher with histopathology training and from the fact that cell selection requires a lot of time from the researcher.

From the point of view of its output the method does not allow for comfortable procurement of large numbers of cells for different array-based methods or proteomic analysis and is hard to use in the case of scattered cells. Sometimes the need may rise for subcellular dissection and currently this technique may not be accurate enough for this purpose.

CARDIOTOXICITATEA LA ANTRACICLINE. MECANISME, METODE DE DEPISTARE PRECOCE, POSIBILITĂŢI DE INFLUENŢARE TERAPEUTICĂ

Irina-Iuliana Costache, A. Petriş

CARDIOTOXICITY OF ANTHRACYCLINES (Abstract): It is a well known fact that the antitumor agents like the anthracyclines induces a dose-related cardiotoxicity and more to add, the new agents used in the treatement of breast cancer may stimulate these cardiotoxic effects, causing in the end an increased morbidity and mortality rate by cardiovascular diseases. Cardiotoxicity caused by anthracyclines can be divided into 3 types: acute (during administration), early (several days to month following administration) and late (years to decades following exposure to anthracyclines). Mechanisms of this cardiotoxicity are very complex: myocyte damage has been attributed to the production of toxic oxygen free radicals, which cause lipid peroxidation of membranes leading to vacuolation, irreversible damage and myocyte replacement by fibrous tissue. Clinical manifestations of anthracycline cardiotoxicity are variable, depending in part upon the time course of appearence (acute, early or late). A number of risk factors for the development of anthracyclines cardiotoxicity have been identified. The strongest predictor is cumulative dose, age, concomitant administration of other chemotherapeutic agents and underlying heart disease. Approaches to reducing anthracyclines cardiotoxicity involved the use of novel infusion protocols, the development of new anthracycline compounds, the use of adjunctive agents, endomyocardial biopsy and noninvasive monitoring of cardiac function. **Key words**: ANTHRACYCLINES, CARDIOTOXICITY, OXYGEN FREE RADICALS

Antraciclinele (AC) sunt printre cei mai activi agenţi utilizaţi în tratamentul cancerului de sân, utilizarea lor în regimuri terapeutice combinate îmbunătăţind atât evoluţia bolii, cât şi supravieţuirea acestor pacienţi (1, 4, 16). Din nefericire, utilitatea clinică a antraciclinelor este limitată de toxicitatea cardiacă, prin efect cumulativ doză-dependent, toxicitate care în final, duce la insuficienţă cardiacă (4, 5, 6, 16).

Paralel cu efectele benefice asupra cancerului creşte şi numărul pacienţilor care dezvoltă fenomene de cardiotoxicitate. Mai mult, noii agenţi utilizaţi în tratamentul cancerului de sân pot potenţa aceste efecte cardiotoxice (ex. trastuzumab).

Antraciclinele au fost izolate din culturi de *Streptomyces peucetius* (specie de actinobacterii) de către Federico Arcamone, în 1960 (4). În timp au devenit componentă esenţială în tratamentul cancerului de sân, în combinaţie cu terapia adjuvantă, reprezentând standardul în stadiile precoce de boală. Mai sunt utilizate în tratamentul anu-

mitor forme de leucemii, limfoame, cancer uterin, ovarian, pulmonar.

Cele mai utilizate sunt doxorubicina şi epirubicina, derivat sintetic de doxorubicină. Alţi agenţi utilizaţi sunt: daunorubicina, idarubicina, valrubicina.

Se cunosc **3 mecanisme de acţiune** (4, 5, 6): 1) Inhibarea sintezei de ADN şi ARN prin intercalarea între lanţurile de ADN şi ARN, prevenind replicarea celulor canceroase cu creştere rapidă; 2) Inhibarea topoizomerazei II prin aceasta blocând transcripţia şi replicarea ADN; 3) Producerea (mediată de fier) a radicalilor liberi de oxigen care lizează ADN-ul şi membrana celulară.

Utilizarea pe termen lung este limitată de apariţia cardiomiopatiei şi a insuficienţei cardiace (4). Efectele toxice ale antraciclinelor la supravieţuitorii de durată cu cancer, pot duce la creşterea mortalităţii şi morbidităţii cardiace. Există dovezi care arată că efectele cardiotoxicităţii cresc la supravieţuitorii pe termen lung, de la 2% după 2 ani la 5% după 15 ani.

Cardiotoxicitatea la antracicline poate fi împărţită în 3 tipuri: acută, precoce şi tardivă, în funcţie de relaţia cu tratamentul.

Forma acută apare în timpul perfuziei cu AC sau în prima săptămînă. Tahicardia sinusală este cel mai obişnuit simptom, însă au fost raportate şi aritmii (tahicardie ventriculară). Au fost descrise: miopericardite şi insuficienţă ventriculară stângă acută. Această formă se poate însoţi de modificări electrocardiografice, cum ar fi: modificări nespecifice ale segmentului ST şi undei T, scăderea amplitudinii complexului QRS, alungirea intervalului QT, aritmii (tahicardie sinusală, aritmii supra-şi/sau ventriculare, tahicardii joncţionale), blocuri atrioventriculare sau de ramură. Incidenţa formei acute este aprox. 1% şi de obicei dispare la oprirea tratamentului. Nu este clară relaţia între toxicitatea acută şi dezvoltarea ulterioară a cardiotoxicităţii întârziate (7).

Cardiotoxicitatea precoce apare în primul an după tratamentul cu antracicline. Pacienţii pot dezvolta modificări electrofiziologice, disfuncţie ventriculară stângă, simptome de insuficienţă cardiacă manifestă. Momentul maxim de apariţie al acestor tulburări este la 3 luni de la ultima doză de antracicline, iar mortalitatea la aceşti pacienţi este ridicată.

Debutul tardiv al cardiotoxicităţii este la peste un an după terminarea tratamentului. Pacienta iniţial asimptomatică poate dezvolta disfuncţie VS, insuficienţă cardiacă, aritmii ventriculare severe şi chiar moarte subită (4).

Unii autori folosesc termenul de cardiotoxicitate „cronică" forma care apare în timpul primului an de tratament şi cardiotoxicitate „cu debut tardiv" forma care apare după un an de la întreruperea completă a tratamentului. Ca manifestări ale acestui tip de cardiotoxicitate s-au descris: scăderea fracţiei de scurtare (cu o incidenţă de 18%) şi creşterea postsarcinii, anomalii care preced o viitoare decompensare cardiacă.

Cardiotoxicitatea tardivă la antracicline se pare că este mai frecventă la vârste tinere şi la sexul feminin (1, 4, 16).

Mecanismul cardiotoxicităţii AC este încă incomplet elucidat. Modificările miocardice care apar după tratament includ: pierderi de miocite prin apoptoză sau necroză, pierderea de miofibrile, distensia reticulului sarcoplasmatic (prin interferarea cu receptorii rianodini), balonizare mitocondrială.

Una din ipotezele cardiotoxicităţii induse de doxorubicină este cea conform căreia doxorubicina ar creşte speciile reactive de oxigen (ROS) în mitocondriile miocitelor,

mai mult decât în alte ţesuturi. AC pot induce generarea de radicali liberi de oxigen pe 2 căi principale: o cale nonenzimatică care utilizează fierul şi un mecanism enzimatic care utilizează lanţul respirator mitocondrial. Radicalii liberi sunt toxici puternici putând provoca leziuni directe ale proteinelor, lipidelor şi ADN. Miocitele adulte sunt cele mai susceptibile. Administrarea doxorubicinei la om este urmată de creşterea nivelelor plasmatice de ROS şi produşi ai peroxidării lipidelor şi scăderea nivelelor plasmatice şi tisulare de antioxidanţi. Nivelul stresului oxidativ indus de doxorubicină este de 10 ori mai mare în cord decât în ficat, rinichi şi splină.

Studiile la nivel de gene pe şoarece au arătat că esenţială pentru apariţia efectelor cardiace ar fi HER2, o protooncogenă, membră a familiei erbB de tirozinkinaze transmembranare, iar deleţia HER2 ar duce la apariţia cardiomiopatiei dilatative (1, 4, 5, 7, 9). La şoarecele deficient în proteina HER2 sau în ligandul său asociat neuregulina (NRG), un peptid paracrin cu rol de mesenger care activează HER 2, antraciclinele au rol în declanşarea disfuncţiei ventriculare stângi. Aceste observaţii au furnizat o explicaţie pentru cardiotoxicitatea crescută apărută după administrarea concomitentă de antracicline şi trastuzumab, un anticorp monoclonal antiHER2. Ca răspuns la expunerea acută la antracicline, calea de supravieţuire a cardiomiocitelor este activată de către neuregulinele care leagă HER2: heterodimerul HER4, prevenind moartea cardiomiocitelor. Traztuzumabul, prin inhibarea receptorului HER2 interferă cu această cale şi favorizează efectele cardiotoxice ale antraciclinelor.

De asemenea, se pare că antraciclinele produc inhibiţia selectivă a expresiei unor gene din miocite, cum ar fi cele pentru actină, troponină, lanţurile uşoare de tip 2 pentru miozină, izoforma M pentru creatinkinază, care pot explica pierderea de miofibrile asociată cardiomiopatiei. Aceste fenomene se adaugă injuriei produse de eliberarea de radicali liberi, supraîncărcării celulare cu calciu, perturbărilor funcţiei adrenergice, eliberării de amine vasoactive şi toxicităţii celulare produse de metaboliţii doxorubicinei. De asemenea, eliberarea de citokine proinflamatorii (implicată şi în alte forme de disfuncţie ventriculară) este un factor adjuvant în apariţia cardiotoxicităţii la antracicline (10).

Supraîncărcarea intracelulară cu calciu poate duce la moarte celulară. Doxorubicina favorizează influxul de calciu în miocit şi eliberarea de Ca din reticulul sarcoplasmic. Injuria membranei celulare de către radicalii liberi pare să favorizeze acest influx intracelular de calciu, sugerând că cele 2 mecanisme ar fi în legătură (5). La acestea se adaugă disfuncţia adrenergică care constă în fenomenul de *downregulation* a receptorilor beta adrenergici din miocard (4).

Studii recente au arătat că citokinele proinflamatorii circulante pot fi legate strâns de evoluţia disfuncţiei ventriculare şi a dilataţiei cardiace (4, 5, 6, 10). Doxorubicina induce eliberarea factorului alfa de necroză tumorală din macrofage şi a interleukinei 2 din monocite, ambii cu efecte cardiotoxice, prin intermediul unor receptori specifici la nivel miocardic. Eliberarea de citokine este diferită însă în funcţie de tipul tumorii (4).

În ceea ce priveşte cardiotoxicitatea tardivă la antracicline, ea apare la pacienţii trataţi cu antracicline, după o perioadă destul de lungă de compensare. Disfuncţia ventriculară progresivă apare la distanţă de injuria miocardică iniţială, fiind posibilă

intervenţia unor factori *trigger*: sarcina, intervenţii chirurgicale, infecţii virale acute etc.

Factori de risc ai cardiotoxicităţii la antracicline:

Cel mai puternic factor de risc se consideră a fi doza cumulativă. Alţi factori de risc potenţiali sunt: frecvenţa mare a curelor, vârsta (atât cea înaintată, cât şi vârsta foarte tânără), sexul feminin, coexistenţa altor factori de risc cardiovascular sau a unei boli cardiace preexistente, HTA, iradierea concomitentă mediastinală, asocierea altor agenţi chimioterapici. Este încă neclar dacă aceşti factori acţionează în sens aditiv cu antraciclinele sau le potenţează efectul (1, 4).

O doză cumulativă crescută de antracicline este cel mai recunoscut factor de risc pentru injuria cardiacă şi rămâne în continuare cel mai bun predictor pentru disfuncţia cardiacă subsecventă. Primele observaţii au fost ale lui Von Hoff într-o analiză retrospectivă care a arătat că toxicitatea la antracicline şi insuficienţa cardiacă au fost dependente de doză, iar incidenţa complicaţiilor a crescut paralel cu doza de doxorubicin. Procentul estimat de pacienţi care au dezvoltat insuficienţă cardiacă a fost de 3% la doza de 400 mg/m^2 şi a crescut la 7% la doza de 550 mg/m^2 şi la 18% la doza de 700 mg/m^2. Aceasta a dus la recomandarea ca doza limită cumulativă de doxorubicin de-a lungul vieţii să nu depăşească 450-550 mg/m^2. Studiile ulterioare au confirmat această observaţie cu menţiunea că stabilirea dozei cumulative trebuie să ţină cont şi de vârstă, precum şi de alţi factori de risc asociaţi cu impact pe mortalitatea de cauză cardiovasculară (1, 4).

Vârsta. Există studii care au sugerat faptul că efectul cardiotoxic al antraciclinelor este mult mai pronunţat odată cu înaintarea în vârstă. Astfel, în sprijinul acestei idei vine o analiză retrospectivă reprezentată de 3 trialuri clinice care au cuprins 630 de pacienţi trataţi cu doxorubicin, în care Swain şi colab. au arătat că pacienţii cu vârste peste 65 de ani ar fi de 2,25 ori mai predispuşi să dezvolte afectare cardiacă după terapia cu antracicline, comparativ cu cei cu vârste sub 65 ani, dar efectul este mai pronunţat la doze cumulative peste 400 mg/m^2. Numărul pacienţilor din acest subgrup este însă mic. Alte studii (*SEER – Surveillance, Epidemiology and End Results*) au raportat o creştere de 2 ori a riscului de cardiomiopatie şi cu 40% a riscului de insuficienţă cardiacă la femeile cu cancer de sân în fază precoce, tratate cu antraciclină. Aceste studii au arătat că insuficienţa cardiacă a fost asociată cu vârsta, rasa neagră, prezenţa altor comorbidităţi, a factorilor de risc cardiovascular şi a unui istoric de boală cardiacă. Riscul de insuficienţă cardiacă în aceste studii a fost mai mare decât în alte trialuri ce au utilizat altă medicaţie şi în care pacienţii au avut vârstă mai tânără (1, 2, 4).

Metode de depistare a cardiotoxicităţii la AC. Detectarea cardiomiopatiei induse de antracicline în stadiul subclinic, utilizând fracţia de ejecţie a VS în repaus şi fracţia de scurtare este o metodă suboptimală, întrucât dozele convenţionale de antracicline determină injurie miocardică permanentă şi reducerea rezervei funcţionale a miocardului. În plus, mecanismele acestei cardiotoxicităţi (deja amintite mai sus) sunt mult mai complexe la nivel celular: eliberare de radicali liberi, disfuncţie adrenergică, supraîncărcare cu calciu, eliberarea de citokine cu efect cardiotoxic. Billingham et al. au descris o metodă de

apreciere a cardiotoxicităţii la antracicline pe baza unui scor semicantitativ bazat pe metode histologice – respectiv biopsia endomiocardică- care se pare că se corelează bine cu doza cumulativă de antraciclină. Se pare că biopsia endomiocardică este cel mai fidel indicator de apreciere a cardiotoxicităţii la antracicline. Erori pot apare în cazul biopsiei la nivelul VD dacă leziunile sunt focale sau dacă injuria celulară afectează predominant VS. De asemenea limitele acestei metode derivă şi din imposibilitatea efectuării pe scară largă, a repetării ei la nevoie şi mai ales la copii (12).

Angiocardiografia cu radionuclizi este utilizată pe scară largă pentru a monitoriza cardiotoxicitatea precoce indusă de antracicline. Pe baza acestei metode, Allexander şi colab. au sugerat că scăderea fracţiei de ejecţie cu 15% sau o fracţie de ejecţie de bază sub 40% identifică pacienţii cu risc crescut de decompensare cardiacă. Metoda are însă limite legate de faptul că determinarea fracţiei de ejecţie de repaus are senzitivitate scăzută în ce priveşte detectarea cardiotoxicităţii precoce la antracicline întrucât nu există o corelaţie între modificările morfologice care pot fi semnificative şi fracţia de ejecţie care poate fi încă în limite normale. Studii cu radionuclizi la efort pot creşte şansele de depistare a cardiotoxicităţii precoce. Limita metodei este legată de imposibilitatea ca unii pacienţi să fie supuşi unui test de efort (9, 13).

Ecocardiografia bidimensională este o altă metodă noninvazivă de apreciere a cardiotoxicităţii la antracicline, mai ales la copii. Parametrii cei mai utilizaţi sunt fracţia de ejecţie şi fracţia de scurtare, cu aceleaşi limite ca şi în cazul metodei precedente (14).

Parametrii care caracterizează funcţia diastolică au fost de asemenea studiaţi în ceea ce priveşte utilitatea lor în depistarea şi aprecierea injuriei cardiace induse de antracicline. Cardiotoxicitatea cronică la antracicline determină îngroşarea importantă de tip fibros a endocardului cu impact asupra relaxării şi umplerii ventriculare ducând în final la disfuncţie diastolică (scăderea raportului E/A şi creşterea timpului de relaxare izovolumic), modificări care au apărut înaintea scăderii fracţiei de ejecţie. Conform majorităţii studiilor, disfuncţia diastolică precede disfuncţia sistolică la pacienţii trataţi cu antracicline. La copiii trataţi cu antracicline însă, se pare că fracţia de scurtare este un parametru mult mai fidel decît anomaliile de funcţie diastolică în aprecierea cardiotoxicităţii la antracicline.

Dopplerul tisular permite aprecierea velocităţilor sistolice şi diastolice ale pereţilor ventriculari şi ale inelului mitral, fiind mult mai performant în aprecierea funcţiei diastolice a VS comparativ cu ecocardiografia Doppler convenţională (1, 14). Dopplerul tisular poate evidenţia modificări ale funcţiei regionale care nu pot fi obiectivate prin simpla apreciere a fracţiei de ejecţie.

O metodă şi mai fidelă de cuantificare a deformării regionale a VS bazate pe principii de inginerie mecanică este „*strain rate*" care detectează modificările precoce ale funcţiei sistolice a VS şi care se corelează cu markerii biochimici şi inflamatori (1, 14).

Detectarea cardiotoxicităţii tardive la antracicline

Apariţia la distanţă de terapia cu antracicline a unor disfuncţii la nivel cardiac au impus necesitatea unor metode de depistare precoce a acestor modificări, mai ales la pacienţii asimptomatici. Întrucât nu există întotdeauna o corelaţie bună între fracţia de ejecţie şi cea de scurtare cu scăderea capacităţii funcţionale s-a propus utilizarea ecocar-

diografiei de stres cu dobutamină şi a angiografiei cu radionuclizi combinată cu testare de efort, mai fidele în depistarea precoce a disfuncţiei ventriculare stângi subclinice.

Disfuncţia diastolică poate fi de asemenea observată precoce la pacienţii care vor prezenta tardiv disfuncţie sistolică. În urmărirea pe termen lung a pacienţilor cu leucemie trataţi cu antracicline au fost observate cazuri de cardiomiopatie restrictivă după tratamentul chimioterapic. Au fost identificaţi câţiva parametri asociaţi cu un prognostic nefavorabil: scurtarea timpului de decelerare a undei E, creşterea velocităţii undei E (aspectul de pseudonormalizare a raportului E/A). Disfuncţia diastolică se corelează strâns cu simptomele congestive pulmonare la pacienţii cu cardiomiopatie dilatativă indusă de antracicline.

Majoritatea acestor metode amintite mai sus obiectivează anomalii ale funcţiei cardiace, însă după ce au avut loc modificări structurale şi pierderi celulare semnificative.

Din acest motiv pentru detectarea şi prevenirea cardiotoxicităţii într-un stadiu cât mai precoce, se consideră că markerii biochimici sunt mult mai fideli (1). Dintre aceştia, studiaţi au fost: peptidul natriuretic cerebral (BNP), endotelina I, troponinele (T şi I), mioglobina, creatinkinaza (CK, izoenzima MB) care sunt markeri relevanţi ai injuriei miocardice şi au fost asociaţi cu afectarea funcţiei sistolice şi diastolice a VS la pacienţii trataţi cu antracicline. Injuria miocardică sub tratamentul cu antracicline este cauzată de stresul oxidativ şi implicit speciile reactive de oxigen. Reducerea doxorubicinei de către enzimele microzomale NADPH dependente duce la generarea ROS. Celulele cardiace, prin intermediul unei dehidrogenaze NADH mitocondriale (absentă în alte tipuri celulare), generează cantităţi foarte mari de ROS în prezenţa doxorubicinei. Mai mult s-a sugerat că citokinele proinflamatorii pot contribui la apariţia cardiomiopatiei dilatative (7, 9, 10). Interleukina 6 şi receptorul său solubil (sIL-6R) sunt crescute la pacienţii cu insuficienţă cardiacă, în special la cei cu caşexie şi decompensare edematoasă (1). Nivelul citokinelor creşte paralel cu clasa NYHA. Alţi markeri studiaţi în ceea ce priveşte cardiotoxicitatea AC au fost factorul de necroză tumorală (TNF alfa) şi receptorul său solubil de tip 1 (sTNF alfa R1), care s-au dovedit markeri fideli de apreciere a injuriei miocardice cu rol predictiv pentru apariţia afectării cardiace subsecvente, anumite studii stabilind chiar o corelaţie între nivelul acestor markeri şi gradul apoptozei (1,4, 7, 9, 10).

S-a observat de asemenea că nivelul glutation peroxidazei (GPx) scade semnificativ după administrarea de AC. Acelaşi comportament îl are superoxid dismutaza (SOD) şi catalaza (1, 4).

Astfel, detectarea precoce a cardiotoxicităţii induse de antracicline prin determinarea acestor markeri s-a dovedit extrem de utilă.

Cum prevenim şi cum tratăm cardiotoxicitatea la antracicline ?

Orice metodă destinată minimalizării efectelor cardiotoxice ale antraciclinelor tebuie să menţină efectul antineoplazic. Strategiile (altele decît monitorizarea cardiacă) elaborate pentru prevenirea cardiotoxicităţii declanşate de antracicline au fost orientate în 3 direcţii principale.

În primul rând, metoda de eliberare a citostaticului poate influenţa cardiotoxicitatea acestuia. Se pare că administrarea perfuziei continui 48-96 de ore cu doxorubicin ar avea efecte cardiotoxice mai reduse comparativ cu administrarea mai rapidă

(15-20 minute). În al doilea rând, administrarea unor analogi structurali ai antraciclinelor ca mitoxantrona şi idarubicina are beneficii încă nedeterminate între cardiotoxicitate şi efectul antineoplazic. În al treilea rând, agenţii cardioprotectori sunt utilizaţi pentru a diminua efectele antraciclinelor asupra cordului.

Există studii care au utilizat inhibitori de enzimă de conversie pentru tratamentul pacienţilor care au prezentat disfuncţie contractilă după tratament cu antracicline. Se aşteaptă încă rezultate referitoare la efectul preventiv al acestor inhibitori. De asemenea, administrarea tratamentului digitalo-diuretic la pacienţii care au dezvoltat insuficienţă cardiacă pare a fi benefic (4, 16).

Dezrazoxane (ICRF-187) este un cardioprotector utilizat în unele studii pentru a reduce riscul de cardiotoxicitate la antracicline, fără a afecta răspunsul la chimioterapie şi supravieţuirea globală (15). Administrarea sa concomitent cu tratamentul chimioterapic se pare că atenuează efectele cardiotoxice. ICRF 187 este un agent chelator de fier care reduce generarea de radicali liberi produsă de antracicline, inclusiv la copii. Este aprobat şi utilizat clinic doar la femeile cu cancer de sân metastatic după o doză cumulativă de de doxorubicin de 300 mg/m^2, întrucât se pare că ar diminua efectul şi eficacitatea antitumorală a antraciclinelor în stadiile precoce de cancer.

Studii efectuate pe animale de laborator au indicat că probucolul – un hipolipemiant similar ca structură cu vitamina E furnizează cardioprotecţie faţă de injuria miocardică indusă de doxorubicin. Probucolul creşte la nivel miocardic activitatea glutation peroxidazei şi superoxid dismutazei prin aceasta având efect antioxidant. Îmbunătăţirea statusului antioxidant al miocardului are loc concomitent cu reducerea peroxidării lipidelor indusă de antracicline (8, 16). Probucolul nu interferă cu efectele antitumorale ale antraciclinelor. Sunt necesare studii pentru extrapolarea acestor rezultate la om.

Reducerea supraîncărcării celulare cu calciu produsă de antracicline constituie o altă ţintă terapeutică în cardioprotecţie. Experimentele pe animale au sugerat că antagoniştii de calciu reduc cardiotoxicitatea indusă de antracicline. Blocanţii beta-adrenergici previn supraîncărcarea cu calciu a cardiomiocitelor, indusă de antracicline, contracarând efectul cardiotoxic al catecolaminelor. Beta blocantele lipofile ca propranololul previn de asemenea peroxidarea lipidelor mediată de radicalii liberi. Totodată, metoprololul s-a dovedit eficient în cardiomiopatia indusă de antracicline, cardiomiopatia dilatativă idiopatică şi insuficienţa cardiacă ischemică. Se pare că administrarea precoce, încă din stadiile subclinice a inhibitorilor ECA şi a beta blocantelor ar putea reduce efectele cardiotoxice ale antraciclinelor şi implicit mortalitatea legată de aceasta (1, 3, 4, 11, 16).

De asemenea se pare că utilizarea formulelor lipozomale de daunorubicin şi doxorubicin par să fie mai puţin citotoxice pentru ţesutul cardiac comparativ cu formulele nonlipozomale.

În concluzie, cardiotoxicitatea la antracicline limitează efectele benefice anticanceroase ale acestora, din acest motiv se impune necesitatea unor metode cu senzitivitate crescută în ceea ce priveşte depistarea precoce a disfuncţiei cardiace. În plus, specificitatea oricărui test trebuie să permită cu acurateţe analiza raportului cost - beneficiu în ceea ce priveşte utilizarea terapiei antitumorale.

BIOCOMPATIBILITY TESTING OF CHITOSAN HYDROGELS (Abstract): Chitosan is a linear, natural cationic polysaccharide comprising β-1,4 linked glucosamine and N-acetyl-D-glucosamine. Hydrogels of chitosan were prepared by crosslinking with varying amounts of glutaraldehyde. It can be used as a bacteriostatic, fungistatic and coating agent, and the gels and suspensions may play the role of carriers for slow release or controlled delivery of drugs, as an immobilizing medium and an encapsulation material. **Material and methods:** Chitosan and glutaraldehyde were used to prepare the hydrogels and their characteristics were investigated by Fourier transform infrared (FT–IR) spectroscopy and the inhibitory effect on cellular growth was tested by chemiluminescence assay. The hemolytic activity was also determined by direct contact with human blood and the concentration of hemoglobin was spectrophotometrically measured. **Results and discussion:** Chitosan hydrogels have no inhibitory effect on cell growth, and hemolytic action below 1%, which means good blood compatibility; therefore they are promising materials. **Keywords**: CHITOSAN, HYDROGEL, CELL VIABILITY, HEMOCOMPATIBLE.

The increasing need to develop new biodegradable materials for medical purposes like skin tissue engineering, wound cover or dressings and barrier-membranes appeared with the high demand for skin replacements and skin repair treatments. An ideal material to be use as a wound dressing should associate availability with minimal storage requirements, long shelf life, versatility and biocompatible behavior.

Many polymeric materials have been investigated for the purpose of wound covering on account its importance in the treatment of burns, prevention of post surgical adhesions and cosmetic surgery. Among them the biodegradable polymers from renewable resources e.g. starch, collagen, gelatin, chitosan, alginate, represent one alternative approach, since these polymers are widely available in nature, are biodegradable and non-toxic. A proper material for wound dressing should maintain a moist environment at the wound/ dressing interface and absorb excess exudates without leakage to the surface of the dressing, to provide thermal insulation and mechanical resistance, bacterial protection, to allow gaseous and fluid exchange, absorb wound odor, to be non-adherent to the wound and easily removed without trauma, non-toxic, non-allergenic and non-sensitizing, sterile (1).

In last years, much attention has been paid to the development of hydrogels from natural, biodegradable and biocompatible polymeric materials. (2) Among other biodegradable polymers, chitosan, a linear polysaccharide, has been found to be a good chemical entity for synthesizing hydrogels because of its greater crosslinking ability due to the presence of amino ($–NH_2$) groups. Chitosan is a linear, natural cationic polysaccharide comprising β-1,4 linked glucosamine and N-acetyl-D-glucosamine and its potential applications of chitosan in medicine can only be exploited if its usable forms are properly developed and prepared, in solution and gel. It can be used as a bacteriostatic, fungistatic and coating agent (3-5) Gels and suspensions may play the role of carriers for slow release or controlled delivery of drugs, as an immobilizing medium and an encapsulation material (6-9). Film and membranes are used in dialysis, contact lenses, dressings and the encapsulation of mammal cells, including cell cultures (10-12). Chitosan sponges are used in dressings, and to stop bleeding of mucous membranes (13). Chitosan fibres there are used as resorbable sutures, non-wovens for dressings, and as drug carriers in the form of hollow fibres (14).

Wang et all (15) investigated smooth surface chitosan microspheres which were prepared by emulsion and crosslinking method. They preformed dynamic blood clotting test showing that chitosan microspheres can shorten the clotting time. By comparing the lowly hemolytic activity with the highly erythrocyte agglutination, they showed that chitosan only induce the adhesion of erythrocytes but not seriously damage the cell membrane.

Present study is dealing with the investigation of hemocompatibility and cell viability of chitosan based sponges. The sensitivity of the chemiluminescent assay was enhanced by using a metal catalyst and quinones suitable to microorganisms. The detectable cell density of viable bacteria and yeast was found to be approximately several thousand of colony forming unit (CFU)/ml. The modified chemiluminescent assay was applicable to detect single S. POmbe after 4 hours cultivation and centrifugation. The conditions for the rapid chemiluminescent assay are discussed herein.

EXPERIMENTAL

Materials

Chitosan, an Aldrich product, with a relative molecular weight of 400 kDa and a deacetylation degree of about 68 % determined by Moore and Roberts's method on the base of FT-IR spectrum was used. Glutaraldehyde used as crosslikning agent was purchased from Fluka as solution 50wt%.

Preparation method of hydrogel based chitosan

Solutions of 1 wt% Chitosan (CS) in acetic acid solution 1 wt% were prepared by continuously stirring about 4 hours in order to completely dissolution of chitosan. The samples of chitosan were crosslinked with different amounts of glutaraldehyde (GA) (CS: GA of 1:0.5; 1:3 v/v %) obtaining gels, which were repeatedly washed with twice-distilled water to remove the excess of GA.

Investigation methods

The freeze-dried hydrogels based on chitosan with different amount of crosslinking agent were spectroscopically analyzed, to evidence the structure differences between hydrogels of chitosan crosslinked with various amounts of GA and to asses

chemical modification. The ATR-FT-IR spectra were recorded using a Vertex 70 Bruker Spectrometer, through reflexion on a diamond crystal with an angle of 45 degrees.

Chemiluminescence assay

The chemiluminescence assay was used for the detection of viable cells according to Yamashoji method (16). A highly sensitive and specific assay method was developed for the detection of viable *Schizosaccharomyces pombe* wild type as an indicator organism in water, using Nucleic-Acid-Sequence-Based Amplification (NASBA) and electrochemiluminescence (ECL) analysis. (16)

This assay is composed of two steps: (A) 10 min incubation of microorganisms with quinone and (B) 2 seconds of photon counting upon the injection of luminol. Viable microorganisms can reduce quinone to produce quinol or semiquinone radicals, which generate active oxygen species during their autoxidation in culture during step A. The production rate of active oxygen species is determined by luminol-dependent chemiluminescence during step B and is proportional to the viable cell's number. The proposed mechanism for menadione - catalyzed production of active oxygen species by viable cells is represented in figure 1.

The calibration curve of control samples (*S Pombe* cultivated in absence of polymers) is presented on figure 1 where relative light units (RLU) were plotted versus cells/ ml concentration.

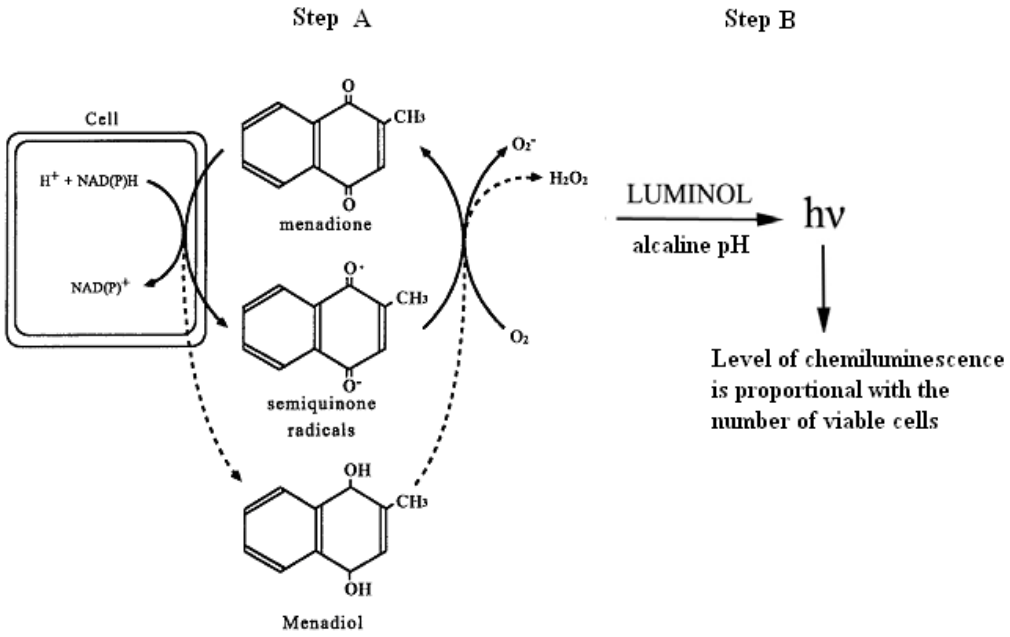

Fig. 1. Mechanism for menadione - catalyzed production of active oxygen species by viable cells (16)

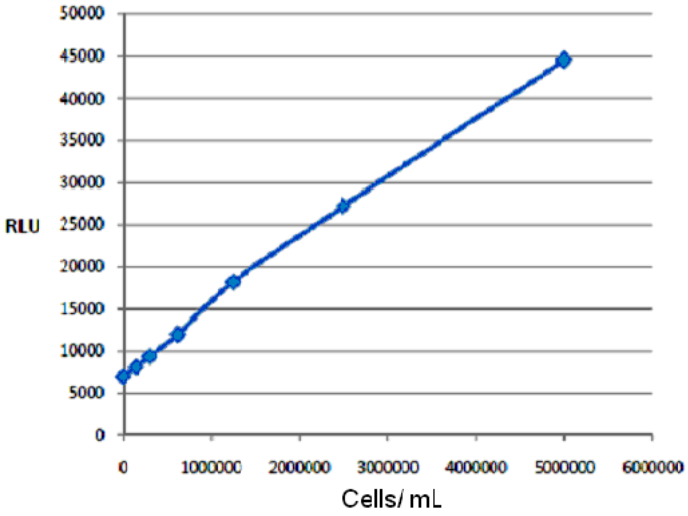

Fig. 2. Standard curve of control samples (S Pombe cultivated in absence of polymers)

Hemolysis tests

The sampling of blood was done from healthy patients and each hydrogel was tested with blood from 1 patient; the distilled water was used as positive reference and the plasma obtained from the blood sample was used as negative reference. From each recipient of blood was taken 1.5 ml of blood which are enough to ensure the contact with the hydrogel. The tested biomaterials in direct contact with blood were incubated at 37 ^{o}C during 2 hours and then centrifuged for 6 min at 5000 rpm. Prior to be spectrophotometrically measured plasma is diluted 11 times with Tris buffer adjusted with HCl to have a pH about 8 (62.5 mmol/L). The positive reference, the distilled water was prepared by blood hemolysis with distilled water in a ration of 1:11; the hemolyzed solution is incubated further during 2 hours at 37 ^{o}C and the diluted 100 times in order to be spectrophotometrically analyzed.

The used method for determination the hemoglobin concentration from plasma is the polychromatic method of Noe (17) the absorbance being measured at 380, 415 and 470 nm.

The degree of hemolysis can be calculated according the following equation:

$$Hemolysis\ (\%) = (C - C_n)/(C_p - C_n) \times 100$$

Where: C hemoglobin concentration on analyzed sample, C_n hemoglobin concentration for negative reference şi C_p hemoglobin concentration for positive reference.

RESULTS AND DISCUSSION

FT-IR spectra

FT-IR spectra - fig. 3 - revealed that the intensity of bands at 2900-2800 cm^{-1} increased with the increasing amount glutaraldehyde.

In order to evidence the structure of hydrogels and the degree of crosslinking the main bands (18) were assigned to be as: 900-1000 cm^{-1} which are characteristic bands of polysaccharide structure, while bands at 1650 cm^{-1} and 2900-2880 cm^{-1} assigned to υNH-CO-COOR and respectively C-N and C-H could appear because of crosslinking.

Cell toxicity assays

The hydrogels based on chitosan crosslinked with glutaraldehyde exhibit potential utility for many biomedical applications due to their gel state. In figure 4 is presented the cell viability as results of chemiluminescent assays to detect the viability of S. Pombe after 4-h cultivation and centrifugation.

Cells viability was calculated by comparison with control samples (*S Pombe* cultivated in absence of polymers), considered to be 100 % viable cells. The effect of hydrogels on cell growth was evaluated by MTT test, a rapid and economical assay for measurement of cellular viability. The chitosan hydrogels exhibited cell viability comparable with the control sample which means a good biocompatibility and didn't show inhibitory effect on the cell's growth.

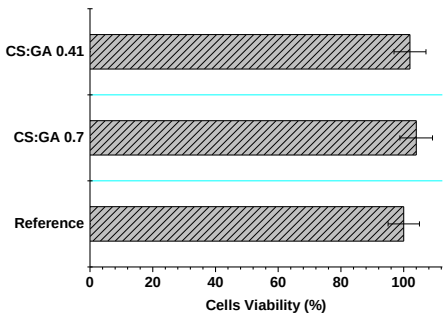

Fig. 4. *S. Pombe* viability detected by chemiluminescence assay

Cells viability was calculated by comparison with control samples (*S Pombe* cultivated in absence of polymers), considered to be 100 % viable cells. The effect of hydrogels on cell growth was evaluated by MTT test, a rapid and economical assay for measurement of cellular viability. The chitosan hydrogels exhibited cell viability comparable with the control sample which means a good biocompatibility and didn't show inhibitory effect on the cell's growth.

Hemocompatability

Table 1 represents the values of hemolysis obtained for the chitosan hydrogels. The method is based on measurement of the hemoglobin released by hemolysis. Hemolysis is regarded as a special significant screening test, once it provides quantification of small levels of plasma hemoglobin, which may not be measurable under *in vivo* conditions. As reported in literature (19), it is not possible to define a universal level of acceptable or unacceptable amounts of hemolysis. Although by definition a blood compatible material should be non-hemolytic, in practice several medical devices cause hemolysis. This means that when such hemolytic effect takes place, it is important to make sure that clinical benefits overcome the risks and that the values of hemolysis are within acceptable limits.

According to ASTM standard, (20) the materials can be classified in three different categories according to their hemolytic index (hemolysis %). Materials with percentages of hemolysis over 5% are considered hemolytic; while the ones with hemolytic index between 5% and 2% are classified as slightly hemolytic. Finally, when the material presents a hemolysis percentage below 2% it is considered as a non-hemolytic material.

The data of table I indicate a hemolysis degree less than 0.6 %therefore they are not hemolytic.

TABLE I

Hemolysis results for the chitosan hydrogels

Sample	A415	A380	A470	Biomaterial concentration	Hemolisys degree (%)
CS:GA0.7	1.0359	0.4035	0.1215	1.245285	**0.5421425**

CONCLUSIONS

Chitosan hydrogels were obtained by chemical croslinking with glutaraldehyde. The biomaterials didn't show inhibitory effect on the cellular growth and the biocompatibility tests were made by hemolysis (plasma hemoglobin) technique, the results obtained showed a good biocompatibility between hydrogels and blood.
